The therapeutic uses of radium are mainly in connexion with cancer, though it is also used for certain other conditions and some dermatological diseases The outstanding medical interest in radium therapy is in determining its value and the best methods of application in the treatment of cancer

Radium therapy has gone through several phases In its earliest years, about 1900, success often attended its use in superficial cancers of low malignancy, this was followed by attempts at dealing with internal growths by implanting radium in platinum or other metal tubes into them Dominici from 1909 onwards insisted on the necessity of avoiding the use of easily absorbed beta and gamma rays when radium was actually inserted into the tissues, and said that only "les rayons ultra-pénétrants" should be used

By the year 1914 radium therapy had already made some progress The principle of selective action was recognised, and there were several laboratories where the effects of the rays on normal and malignant structures were being investigated All this work received a set back during the years of the War, but the ten years that have passed since have been a time of great activity and progress in the subject

France is the home of radium therapy (Curie thérapie they prefer to call it), and it is in no small part due to the systematic researches carried out at the Institut du Radium in Paris, organised by Prof Regaud, that radium therapy has reached its present phase This phase is one in which the definite gains of the past give rise to the belief that radium may be looked upon as a means where by certain localised growths of cancer can be removed as surely as, and generally with less danger than, by surgery This is a big claim, and it is one now generally acknowledged, but it can not seriously be suggested that radium is a cure for generalised cancer Although a primary local ised growth often disappears with radium treatment, in cases where the disease has already spread to glands it is generally true to say that the disappear ance of growth in one part of the body has little recognisable effect upon the spread of the disease outside the range of action of the radium

One of the most important principles that has been recognised during the last five or six years is the significance of the time factor It is certain that the effect of radiation upon a tumour depends not only upon the dose of radiation absorbed by the tumour and the surrounding normal structures, but also upon the time over which the radiation is spread This is nowhere exemplified better than in the treatment of cancer of the tongue For many years these growths, often heavily infected with bacteria, were the despair of those who attempted to treat them by inserting one or two radium tubes, containing perhaps as much as 50 milligrams of the element, and leaving them *in situ* for twenty four hours With this treatment it often happened that the local condition was actually aggravated Since the treatment has been altered and a number of smaller tubes containing only a milligram or two have been inserted and allowed to remain for a week or ten days, so great has been the improvement in the results that, to day, radium combined with surgery is looked upon as the most suitable treatment for cancer of the tongue and buccal cavity

An explanation of this difference in biological reaction has been sought on various lines, for while some think that it lies in the greater probability of cells in the vulnerable state of division being ir radiated in the longer exposure, others believe that cell growth is more affected by prolonged than by short period irradiations, while the opinion is also held that the effect is largely due to the ability of the host to support a low intensity of radiation more easily than a high one It must not be lost sight of, however, that the two types of treatment are fundamentally different in the distribution of the radium in the tissues In the second case the radiation of the region involved is much more uniform and there is more prospect of treating the whole of the growth than in the first case, where one or two tubes containing a large quantity of radium are embedded This distribution necessarily gives a much too heavy dose to the tissues surround ing the tube, while at the same time much of the growth may be outside the lethal range of action

Radium is now an acknowledged agent in the treatment of localised cancer, and every year new methods are being devised in order to deal with the more inaccessible varieties of growths (for example, stomach, œsophagus, brain, etc) But the radium in Great Britain is not enough to treat the numbers of cases of cancer who would probably benefit from its use It is true that the supplies, especially in the London area, have been considerably increased in the last five years, but in Great Britain generally there is a real shortage From a national point of view, if an agent is known to be of remedial value in the treatment of any disease then it would naturally be urged that it should be got, provided there are people enough who know how to use it to the best advantage These two objects are doubtless in the minds of those who have not only to gauge the nation s radium needs but also to find the means of satisfying them It is unthinkable that Great Britain cannot really afford the radium that it requires, but the administration of a quantity, let us say a gram per million of popula tion, calls for a good deal of consideration in medical economics Is the present moment the time for starting a radium centre on the broadest lines where treatment, research, and the teaching of therapy can be carried out ? Would it be better to supple ment the resources of centres in Great Britain which have already earned a certain reputation ? Or would it be better to aim at putting the tech nique of radium therapy into the hands of the general practitioners of the country ?

The final result, in so far as the economic and efficient treatment of cancer by radium is con cerned, is very largely bound up with the decisions of a national character which are likely to be taken in the near future

In the House of Commons on April 16, Mr Winston Churchill announced that the Govern ment has arranged for the publication of the report of the Sub Committee of the Committee of Civil Research on Radium This Sub Committee under the chairmanship of Lord Rayleigh, expressed the opinion that in order to meet the medical require ments of England, Scotland, and Wales twenty grams of radium should be acquired before the end of 1930 It also recommended the election of 'National Radium Trustees' whose duty it should be to hold the funds provided and to purchase and hold radium for the use of an expert body, this expert body to be called the 'Radium Commission' Mr Churchill further stated that the Government has accepted the financial recommendation of the Sub Committee and that it will be prepared to con tribute from public funds, up to a maximum of £100,000, to the extent of £1 for every £1 of private subscription

Obituary.

Sir George Knibbs, C M G

BY the death of Sir George Handley Knibbs at Melbourne, on Mar 30, science in Australia has lost one of her most forceful and enthusiastic workers

Sir George was born in Sydney in June 1858 As a surveyor and civil engineer he took an active part in the topographical survey of New South Wales He then became acting professor of physics at the University of Sydney In 1906 he was appointed Commonwealth Statistician, and in that capacity brought out the Commonwealth Year Book, which, by reason of its comprehensive and accurate nature, is one of the best statistical publications in the world

After serving for fifteen years as Commonwealth Statistician, Sir George Knibbs was appointed in 1921 Director of the Commonwealth Institute of Science and Industry, which post he held until his retirement from public life in 1926 The Institute was then reconstructed as the Council for Scientific and Industrial Research While under his direction, the small staff of the Institute commenced a number of important lines of investigation, some of which have recently passed from success in the laboratory to the sphere of commercial scale tests These included research into the manufacture of paper pulp from Australian hardwoods, power alcohol production, the eradication of prickly pear, and the utilisation of Australian pottery clays Knibbs deplored the inevitable whittling away of funds intended for research purposes, due to political indifference, which lessened the value of the Institute to the nation The constitution of the Institute, however, did not favour its fullest co operation with the universities and other State bodies, nor did the somewhat autocratic manner of the director attract his Australian fellow scientific workers Both features were undesirable in a national research body

Throughout his public life Sir George Knibbs took an active part in social legislation and served on Royal Commissions concerned with education, social and other forms of insurance, taxation of crown leaseholds, trade, and industry As Commonwealth Statistician, he devised the mathematical formulæ on which the Commonwealth land and income taxes are assessed

Though his activities were more of an administrative nature, Sir George contributed to the scientific press numerous monographs on pure mathematics, geodesy, and geodetic instruments His larger contributions include "The Mathematical Theory of Population," "The Census of Wealth," and a recent book, "The Shadow of the World's Future"—a study of the relation of world population growth to food production and migration influences From a statistical basis, he emphasises the need for modification in national policies to avert the danger of over population

Sir George Knibbs was a fellow of the Royal Astronomical Society, an honorary fellow of the Statistical Society, and a member of the International Institute of Statisticians He attended many international congresses, where his sound knowledge of foreign languages, backed by a comprehensive grasp of scientific affairs, made him an able and worthy representative of the Commonwealth Although in recent years his health was failing, this disability seems to have had little effect on the keenness and brilliance which he applied to the welfare of Australian scientific organisations The knighthood bestowed on him in 1923 was regarded in Australia as a fitting recognition of the devoted and brilliant service he had rendered to his country

---

Sir Henry Rew, K C B

The death at his house at Wormshill, Kent, on April 7, at the age of seventy years, of Sir Henry Rew removes a leading authority on agricultural economics and, in the old sense of the word, statistics For some years prior to 1906 he was in charge of the Statistical Branch of the Ministry of Agriculture and Fisheries, and after his promotion in that year to the post of assistant secretary, his predominant interest lay in the annual reports on agricultural statistics, for which he was personally responsible To his work in this field is largely due the fullness and comparability of the series of returns on British agriculture His initiative may be exemplified by the estimates made by a committee of the Royal Statistical Society, from returns from representative dairies and slaughter houses of the production of milk and meat in the British Isles

The two addresses given by Sir Henry Rew as president of the Royal Statistical Society were devoted to "The Organisation of Statistics" and to "The Progress of British Agriculture" In the first of these he emphasised that 'The real question is not the present defects of the official statistics or the delinquencies of official statisticians, but the deficiencies of the present system and the inadequacy of the available resources" After quoting the several high authorities who at different times had urged the importance of the establishment of a centralised statistical department, he expressed his own conviction of the need for "a general overhaul of official statistical machinery, and for some drastic measure for securing co ordination" The function of the Royal Statistical Society should be to assist in forming an appreciative, watchful, and well informed public opinion

Sir Henry's second address to the Royal Statistical Society was largely a historical account of agricultural statistics leading to the important conclusion that while the statistical data were unable to prove the case, an examination of the statistics so far as they were available pointed to the conclusion that a larger quantity of food was being produced at the outbreak of War than at any previous period, and this in spite of a shrinking acreage

MR C E BENHAM

MR CHARLES EDWIN BENHAM, of Colchester, whose sudden death on April 1, at sixty eight years of age, we regret to record, was a representative of the type of scientific amateur of which British science has reason to be proud He followed scientific pursuits, and studied natural processes and events, purely for the love of Nature in all her ways, and by faithful observation and original mind he was able to make some notable contributions to knowledge

Mr Benham was for many years editor of the *Essex County Standard* and spent most of his life in the town of Colchester, where he took a leading part in educational and other movements It is not surprising that "William Gilbert of Colchester" should have attracted his literary and scientific attention, for Mr Benham's methods were of the same experimental and independent character as those of Queen Elizabeth's learned physician In an excellent little book published in 1902 he showed what manner of man Gilbert was, wherein lay his genius, and the spirit of his work which was "that all scientific knowledge must be founded on practical experiment and observation alone, instead of upon speculations and theories evolved out of inner consciousness"

In 1895 Mr Benham devised a colour top by which a curious optical illusion is produced which is not easy to explain Half of a white cardboard disc is coloured black and on the other half a number of black lines are drawn as arcs of a circle On rotating the disc, and viewing it in a bright light, the arcs of some of the circles appear coloured On reversing the rotation the order of the colours reverses The subjective colour effects then exhibited were the subject of a number of letters in NATURE at the time the top was produced, and Mr Shelford Bidwell devoted a paper to them which was published in the *Proceedings of the Royal Society* of Dec 17, 1896

On the experimental side also, Mr Benham developed the twin elliptic pendulum and published a number of papers on harmonic vibrations and vibration figures He was the author of many communications published in NATURE, *Knowledge*, *Science Progress*, *Engineering*, and other scientific journals, and the subjects covered a wide range of practical inquiry, including thermographs, atmospheric electricity, electroscopes, alarum sundials, and iridescent glass Mr Benham was in addition an artist whose water colour drawings are of real distinction, and the author of works on local Essex dialects and the history of Colchester He was an ardent lover of knowledge in all its highest aspects, and his death will be regretted by a wide circle of students who have been stimulated by his work, as well as by his numerous personal friends

PROF F KEHRMANN

DR FRIEDRICH KEHRMANN, professor of organic chemistry at the University of Lausanne, died on Mar 4 We are indebted to the *Chemiker Zeitung* for the following details of his career Born at Coblenz in 1864, Kehrmann became deeply interested in chemistry while still a boy, but being at first unable through lack of means to attend regular classes, he studied by himself He became so proficient in analytical work that he obtained a post as analytical assistant to Fresenius at Bonn In 1887 he graduated at Basel under Nietzki, with whom he carried out an investigation of quinones After graduation he became assistant to Claus at Freiburg, where from his observations upon di ortho substituted quinones he formulated the well known hypothesis of 'steric hindrance,' a generalisation which has been very extensively applied in the study of other branches of organic chemistry

Kehrmann's hypothesis was based upon the hindering effect of two ortho substituents upon oxime formation, and in support of his idea he quoted many other well known examples of inhibited reactions, which had hitherto remained unexplained He was even able to foresee the discovery of steric hindrance in the ortho substituted benzoic acids This prediction was verified shortly afterwards by the work of V Meyer but for some reason or other Kehrmann's claim to priority seems to have been overlooked

Kehrmann moved to Aix le Chapelle and thence to Geneva, where he found in Graebe's laboratory a congenial atmosphere and inspiring companions At Geneva his chief interest was in dyestuff chemistry, to which he made many notable contributions, particularly in the field of azines thio azines, and oxazines To him may also be attributed the origin of the theory of the oxonium salts For a short time he held a post with the firm of Casella and Co, but ill health compelled him to relinquish it Later he took up a teaching appointment at the Municipal School of Chemistry at Mulhausen in Alsace, and in 1910 he was appointed to the chair of chemistry at Lausanne His collected works, which include the spectroscopic examination of whole classes of dyestuffs, have been published in five volumes

WE regret to announce the following deaths

Mr W Worby Beaumont, honorary consulting engineer of the Royal Automobile Club, for ten years a joint editor of *The Engineer* and author of several well known books on motor car engineering, on April 14, aged eighty years

Prof F S Earle, sugar cane technologist at the Tropical Plant Research Foundation at Herradura, Cuba, and president in 1906 of the American Botanical Society, on Jan 31, aged seventy two years

Mr Charles Hunt, an honorary member and past president of the Institution of Gas Engineers, aged eighty six years

Prof Clemens von Pirquet, professor of pædiatrics in the University of Vienna, known for his studies of the mathematical relationship of body measurements to nutritional requirements and for his cutaneous tuberculin reaction, aged fifty four years

Dr Paul Sarasin, president of the ethnographical section of the Natural History Museum of Basle, on April 7, aged seventy three years

News and Views.

Sir Alfred Ewing, Principal and Vice Chancellor of the University of Edinburgh, was presented on April 18 with the freedom of the City of Edinburgh in the Usher Hall in the presence of a large and representative assembly The honour was conferred, as stated in the Burgess Ticket, as a mark 'of the high esteem in which he is held by the citizens of Edinburgh, in testimony of his valuable services to the city and the State, and in recognition of his brilliant and distinguished career as Principal of the University of Edinburgh during a period marked by exceptional difficulty on account of the War and the policy of unprecedented development and expansion of the University The Lord Provost, Sir Alexander Stevenson, who presented the silver casket containing the Burgess Ticket, spoke of Sir Alfred's distinguished career of his services to the University and his efforts to make the University a living force in the City, and of his work at the Admiralty during the War as creator and organiser of the department which achieved great success in intercepting and deciphering enemy wireless messages In his reply Sir Alfred referred to some of the important developments in the University during the thirteen years of his principalship, and at the end stated that he had received from Sir Alexander Grant a cheque for £25 000 and a promise of a like amount within twelve months for the building of a new department of geology After the ceremony, Sir Alfred accompanied by the president of the Students Representative Council, was conveyed from the Usher Hall by way of Princes Street to the City Chambers in a gaily decorated open carriage drawn by students

In 1923 a large wooden building which was erected in 1917 in St Andrew Square, Edinburgh for the use of American troops, was purchased by the University and rebuilt on the new campus near the southern edge of the City adjacent to the Department of Chemistry Early in the following year the Department of Geology was transferred thereto from inadequate premises in the Old College The wooden building is now approaching the limit of its existence, and Sir Alexander Grant s generous gift relieves an anxiety which was becoming acute as to the housing of the Department of Geology This is the second benefaction the University has received from him, for about four years ago he contributed a sum of £50 000 towards the extinction of the debt on the Department of Chemistry In June 1923 he gave £100,000 towards an endowment fund for the Scottish National Library, and in July of last year a further sum of £100,000 for the erection of a suitable building in which to house the Library He was also one of the chief contributors to the fund for the Scottish National War Memorial His name, as Sir Alfred Ewing said is in Edinburgh a synonym for generosity

When a journal has been for thirty years in charge of one man, the reputation of the journal reflects the merits of the editor The case in point is that of *The Mathematical Gazette* and Mr W J Greenstreet Founded and maintained in the interests of school teachers, the *Gazette* has pedagogy in plenty, abundant notes on scholarship mathematics, and reviews which endeavour conscientiously to appraise schoolbooks as they issue in bewildering streams from the publishers But it aims also at helping its readers to understand how mathematics has grown since their own university days, and nowhere are important mathematical treatises subjected to more valuable analysis or more authoritative criticism Keynes has been reviewed by Russell, Eddington by Newall, Weierstrass by Carathéodory, Schrodinger by Fowler, Knopp by Bromwich While Mr Greenstreet has secured for a journal which grew out of the annual reports of a teachers' association the standing implied by such names as these, he has also poured into its pages a wealth of biographical and historical knowledge which has made the *Gazette* the most readable mathematical periodical in the world A testimonial in appreciation of Mr Greenstreet's long and successful editorship has been organised by the Council of the Mathematical Association, which invites the co operation of everyone who feels that such work as his deserves recognition Because of a severe illness which drained his resources two years ago, the testimonial is to take the form of a cheque, accompanied by the names of subscribers but not by a list of amounts The expenses of the fund are being borne by the Mathematical Association, and the work involved has been undertaken by Mr C Pendlebury, 39 Burlington Road, Chiswick, London, W 4, to whom donations should be sent

The pioneers of New Zealand geology include von Haast, James Hector, F W Hutton, and Ferdinand von Hochstetter, the last of whom was born on April 30 1829 The son of an Austrian pastor, Hochstetter took the degree of Ph D and in 1853 joined the Geological Survey of Austria Four years later he became geologist to the famous *Novara* Expedition and on Dec 22, 1858, arrived at Auckland, where his services were at once secured by the Government Von Haast, the German geologist, had arrived the day before, having been sent out to report on the suitability of the country for German emigrants Together, Haast and Hochstetter carried out extensive geological explorations and both published works on the geology of New Zealand Returning to Europe in 1861, Hochstetter settled at Vienna and for many years held the chair of geology and mineralogy at the University there He died on July 21, 1884, and a memoir of him was written by Haast, which was reviewed in our columns on Nov 20, 1884

Prof E V Appleton, Wheatstone professor of physics at King's College, London, has been awarded the Morris Liebmann Memorial Prize for 1929 by the American Institute of Radio Engineers This prize is awarded annually by the board of directors of the Institute to the worker responsible for the most important contribution made to wireless progress during the preceding year Prof Appleton has for

some years been engaged in the study of the scientific problems of radio telephony, chiefly on behalf of the Radio Research Board and the Department of Scientific and Industrial Research In 1924, working in conjunction with Dr Barnett, he was the first to put forward acceptable experimental evidence for the existence of the so called Heaviside layer and the value of its height above the ground More recently, work on similar lines has been carried out under Prof Appleton's direction, in the most part at the Peterborough Station of the Radio Research Board and at King's College, London, where wireless methods have been developed which have led to a great increase in our knowledge of the electrical properties of the upper atmosphere It may be recalled also that Prof Appleton made an announcement in NATURE of Mar 23 last, of the discovery of what is probably a second Heaviside layer He was recently awarded a Wireless Premium by the British Institution of Electrical Engineers for his researches on the causes of wireless signal fading and directional errors

A MOVEMENT to commemorate in an appropriate way the pioneer work of the late Mr W H Dines in the exploration of the upper air and in other branches of practical meteorology was initiated a few months ago by the Royal Meteorological Society The Council of the Society believes that the most suitable form of memorial would be the publication of a collection of Mr Dines's scientific papers in a single volume, and a circular has just been issued inviting promises of subscription to such a volume of about 600 large octavo pages, to be published at a price not exceeding thirty shillings The papers consist almost exclusively of contributions to the publications of a number of scientific societies extending over a period of fifty years , and their re issue in a collected form would not only be a tribute to Mr Dines's original and fruitful work but also would be of real service to science in general and students of meteorology in particular Intending subscribers to the volume should communicate with the secretary of the Royal Meteorological Society, 49 Cromwell Road, South Kensington, S W 7 We trust that the promises to purchase the volume when published will be numerous enough to relieve the Council of any anxiety which may be involved in the cost of publication of a work worthy of one whose researches began a new epoch in the history of meteorology and have led to developments of great practical value

THE American Association for the Advancement of Science held a very successful meeting in New York during the last week of December On behalf of the fifty educational and scientific organisations of the city, Prof Henry Fairfield Osborn, the president, welcomed the Association, which now includes more than 17,000 members, and gave an indication of the programme set for the meeting A reprint of his address has now reached us The programme seems to have been arranged with great regard to the convenience of the public and the scientific worker of wide interests, for separate days were set aside for general sessions each on one particular science, so that geology, physics, biology, chemistry, and anthropology each had its day, and on the evening of the same day a reception and address followed in the corresponding department of the American Museum of Natural History Following the excellent precedent of the British Association, these evening addresses were of a semi popular character designed to attract and stimulate the rapidly growing interest in science manifested in the city of New York and throughout the United States and Canada "The leading *motif* of this science week programme was to offset some of the extreme specialisation of the present day by a more general prospectus of the unity and harmony of various sciences such as prevailed in the unified spirit of the great founders of the Association eighty five years ago " It is a leading *motif* which deserves serious consideration in arranging the programme of the British Association Advantage was taken of the occasion of the meeting to celebrate the centenary of the epoch making glacial theory of Louis Agassiz, one afternoon session being devoted to a symposium of addresses on various aspects of glaciation

ONE of the interesting evening addresses was delivered by Prof W M Wheeler, of Harvard University, on "Present Tendencies in Biological Theory," and this has since appeared in the February *Scientific Monthly* Prof Wheeler makes a strong protest against the critics of biological theory, who find that "biology has been steadily going to the dogs ever since the Renaissance," or that "biology has about reached a stage corresponding with pre Copernican astronomy and physics, and that biologists have not yet discovered a single law, since what they have been fondly calling laws are merely rules or generalisations" He considers that there are at least three recent theories, which, with some mutual adjustment, might yield a provisional synthesis, or at any rate clarify the conflict between the mechanistic and vitalistic points of view These are the theory of emergence or 'holism' propounded by Prof S Alexander, Prof C Lloyd Morgan, and General J C Smuts , the configuration or 'Gestalt' theory , and behaviourism Each of these theories deals with wholes, from different aspects , the first emphasising that the whole has a novel import not apparent in any mere sum or aggregate , the second being more interested in the peculiar irreducibility of wholes as patterns either in space or time than in their novelty , and the third concerned with the action patterns of the whole organism in response to its environment While admitting that certain oppositions must remain in biological theory from the nature of the emergence levels of organisms, Prof Wheeler thinks that many of the oppositions among theories may be elucidated and toned down "by the rejection of a lot of adventitious and mystical notions foisted upon the biological sciences by historians and philosophers "

AN outstanding feature in the recent history of the British Research Association for the Woollen and Worsted Industries is the retirement of the chairman, Sir James P Hinchliffe Sir James, who is well known for his public services in Yorkshire, is a

distinguished figure in the textile industry, and he has, in large measure, been responsible for the development of the present high degree of efficiency of the Association He is succeeded by Lord Barnby, who, in addition to being governing director of one of the largest wool firms in the world, has already rendered much service through the Federation of British Industries and elsewhere, by his advocacy of the importance of the application of scientific method in the development of British industry The Report of the Association for the year 1928–29 contains a complete survey of its activities The effects of selection, breeding, nutrition, climate, and pasturage on particular breeds of sheep, and the consequent effects upon the wool produced, are being investigated, with the financial assistance of the Empire Marketing Board, in conjunction with the Dominions overseas Physical and chemical problems continue to provide an extensive field of investigation Much of this work has already been described in previous reports by the Association The joint research with the Society of Dyers and Colourists upon fastness of dyestuffs and fading of fabrics due to light, perspiration, and other agents, is being continued

The extent and complexity of the purely scientific problems which confront the textile industry at the present time are clearly described in the Report referred to above, and the difficulty of the dissemination of the results of the purely scientific work of the Association in the industry itself has received timely emphasis The better utilisation of research, not merely in the textile industry, but also in British industry generally, is probably one of the most urgent needs of the present time The final Report of Sir Arthur Balfour's Committee on Industry and Trade sounds a warning note upon this point when it states that before British industries, taken as a whole, can hope to reap from scientific research the full advantage which it appears to yield to some of their most formidable trade rivals, nothing less than a revolution is needed in their general outlook on science , and in the case of some industries at least this change of attitude is bound to be slow and difficult, in view of old and deeply rooted industrial traditions The work of the research associations generally will be immensely facilitated if this view gains a wider appreciation amongst all those engaged in industry to day

In his Friday evening discourse, delivered on April 19 at the Royal Institution, Prof O T Jones described a visit to the Grand Canyon, Yellowstone National Park, last summer This is the largest of the national parks in the United States, and is chiefly remarkable for its geological and physiographical features Volcanic accumulations of the Tertiary period make up a large area of the Park and attain a thickness of many thousands of feet The large number of existing geysers and hot springs indicates that the volcanic phenomena are not yet quite extinct Among the most striking of the physiographic features of the area is the great canyon carved by the Yellowstone River on its way from the Yellowstone Lake to join the Missouri Physiographers have usually regarded the Grand Canyon as a product of erosion since the glacial period An examination of sediments in the wall of the Canyon near the Great Fall has shown that they are sands, muds, and conglomerates extending in different places from the rim of the Canyon nearly to the bottom These prove beyond doubt that the Canyon since its excavation has been dammed at some point below, and in the lakes resulting from this process the sediments have accumulated, filling the Canyon to the brim Further investigations have established that the Canyon since its excavation has been dammed by great flows of lava which entered the Canyon from the north and flowed against the drainage of the Yellowstone and its main tributary, the Lamar River A consideration of the profiles of the drainage system shows that prior to the damming episode the Canyon had been eroded in three or four stages or cycles of erosion , each new stage being initiated by uplift of the region The lava flows entered the Canyon while the last cycle of erosion was in progress The results of these discoveries have thrown an entirely new light on the volcanic history of the Park, which will have to be examined anew

The Society for Experimental Biology met at the University of Manchester on April 19 and 20, the meetings being held in the Physiology Department through the kindness of Prof H S Raper Among the numerous contributions were an account of the growth and development of different types of bulbs by Prof F E Weiss, and a stimulating discussion which followed the statement, by Prof D Thoday, of the principles underlying the causal interpretation of plant anatomy Mr M A H Tincker described the effect of varying the daily light duration upon the time of flowering, form, and chemical composition of plants, while Mr E J Collins outlined some experiments on the 'breaking' of tulips Prof H S Raper gave an account of melanin formation among animals, pointing out that a similar mechanism appears to underlie all the cases explored, with possible exceptions among vertebrates Mr J Needham discussed the evolution of the egg and the metabolic limitations which it imposed upon the embryo Prof T H Pear described his work upon the transfer of training in the acquisition of manual dexterity Mr A D Ritchie introduced an interesting discussion on the acid base equilibrium in muscle

The Prime Minister of the Commonwealth has appointed a committee to take charge of the general arrangements for the proposed Australian Antarctic Expedition under Sir Douglas Mawson Sir George Pearce, vice president of the Executive Council, is chairman of the committee, and the other members are Sir Douglas Mawson (or, in his absence, Capt J K Davis, who will be second in command of the expedition), Sir David Masson, Rear Admiral W R Napier, Dr A C D Rivett, and Dr W Henderson The expedition will undertake a coastal survey of the Antarctic continent south of Australia between longitudes 160° and 45° east, the *Discovery* having been placed at its disposal by the British Government

It is anticipated that the ship's complement will number twenty six, and that the scientific staff, including a press correspondent, will be twelve The starting point of the expedition has not yet been determined, but operations will probably begin late in November and continue until the end of April 1930 It is very probable that a second season will be necessary to enable the whole programme of the survey to be carried through

In the article on Christian Huygens in our issue of April 13, p 575, reference was made to the object glass of 122 feet focal length which, according to Weld, was given to the Royal Society by Huygens in 1691 Weld also states that two other object glasses of Huygens' were afterwards presented to the Society by Sir Isaac Newton and the Rev Gilbert Burnet From Prof R A Sampson, Astronomer Royal for Scotland, we learn that the real donor of the first and the maker of all three lenses was Christian's elder brother, Constantine Huygens (1596–1687), and that, collaborating with Prof A E Conrady, Prof Sampson has recently communicated to the Royal Society a paper containing a critical account of these historical lenses Weld's "History of the Royal Society" was published in 1848, but the mistake about the lenses had been pointed out by Uylenbroek ten years before From the *Times* of April 22, we learn that the tercentenary of the birth of Huygens was celebrated the previous week at Leyden, the commemoration being organised by the Royal Academy of Sciences in conjunction with the University of Leyden and various scientific associations A souvenir account of the proceedings is to be published at Amsterdam

The issue of *Vox* for Mar 1, edited by Prof Calzia, of the University of Hamburg, contains an official communication of the International Society of Experimental Phonetics giving an account of the Conference to be held on July 24–31 next in Hamburg, with a list of addresses and demonstrations and an announcement that opportunities will be given for practical training in the methods of the science The published list of members includes experimental phoneticians from nearly every country in Europe and also from America and Asia An account of a new and very practical form of stroboscope for observing the vocal cords is illustrated in detail *Vox* is the official organ of the Phonetic Laboratory of the University of Hamburg, the Phonetic Institute of the University of Vienna, and the International Society of Experimental Phonetics It is sent without charge to members of the International Society

Dr Millais Culpin has contributed an article on noise and hearing, considered from the psychological point of view, to a recent issue of *The Nineteenth Century* (vol 105, No 626) Few of those who most volubly protest against the noises of modern life are content to base their objection on the simple fact that unnecessary noise is irritating to most people, and that certain temperaments may find that irritation harmful to health Instead, a pseudo scientific terminology is used to describe fantastic happenings to the central nervous system Dr Culpin discusses the problem of nervousness, the relation of the nervous temperament to the degree of suffering from noise, the bewildering array of personal peculiarities that confronts any investigator of noise, the domain of the physiological injury when such can be proved to exist The frequently urged view that energy is used up in ignoring noise, sounds plausible, but as it can neither be proved nor disproved it leads nowhere, arguing by analogy, however, there seems no reason to suppose that lack of attention to certain auditory sensations can be of any more danger to the organism than lack of attention to any other sensory stimulation The article is a very timely and necessary corrective to the loose thinking and over simplification characteristic of many writers on the subject Dr Culpin also makes the subject much more valuable by treating it in relation to other problems and not as an isolated phenomenon

An authoritative committee, composed principally of veterinary surgeons in charge of slaughter houses, recently held at Leeds a trial of the Weinberg casting pen, the object of which is to ensure that no suffering shall be inflicted when beasts are cast for slaughter by the Jewish method (shechita) It is therefore satisfactory to know that the report of the committee is entirely favourable The chairman was Prof F T G Hobday, principal of the Royal Veterinary College, and the honorary secretary Capt C W Hume, of the University of London Animal Welfare Society The members included Prof Lovatt Evans, five veterinary surgeons in charge of large abattoirs, and two representatives of animal protection societies It is understood that two further machines having the same object are to be tried out in the near future The subject is one upon which feeling runs very high in some slaughter houses, and in these circumstances it is not easy to ensure the scientific character of the trials by eliminating incalculable human factors The committee will doubtless, however, be fully alive to this consideration

In a recent address to the Institution of Electrical Engineers, Mr J Swinburne gave an account of Sir Joseph Swan's inventions in connexion with the carbon filament electric lamp In the April *Journal* of the I E E, Mr A Campbell Swinton has a note on the part played by Lane Fox Pitt in the invention of this lamp He thinks that neither Mr Swinburne nor Sir Ambrose Fleming in his 'personal recollections,' published in the February issue of the *Journal*, do justice to this inventor, and points out that he was the first patentee of the method of 'flashing' used in making carbon lamps, and was the inventor of the constant voltage system of public lighting with the lamps in parallel In the same journal Mr Swinburne replies that he does not know who invented the method of flashing' In his address he was discussing Swan's work, and as Swan got no help from Lane Fox Pitt's work, it was unnecessary to discuss the work of the latter He mentioned, however, in his address that Pitt did take out a patent on parallel distribution a year before Edison, which, although bad

in law, propounded with luminous clearness parallel distribution, and dispelled for ever the fog about 'the subdivision of the electric light'

AT a meeting held in the Natural History Theatre of the University of Manchester on Feb 23, a provisional committee was appointed to draw up a scheme for co-ordinating the work of the scientific societies, especially those following biological lines of research, in north-western England and Wales The committee has now issued a circular with suggestions for the establishment of a "North Western Naturalists' Union," which will, it is hoped, be definitely inaugurated in June Membership of the Union will be open to individuals as well as to societies in the area proposed, which includes the English counties from Cumberland to Staffordshire and Shropshire, North Wales, and the Isle of Man It is believed that such a Union may be of great service to the local societies, by holding a yearly general meeting and conference, by arranging exchanges of lecturers between the various centres, and by facilitating the publication of papers For many years past there has been at work a strong naturalists' union in north-east Lancashire, and it is hoped that the more comprehensive union now proposed will be a means of help and encouragement to the large number of earnest Nature lovers who pursue their studies in the busy industrial towns and the countryside of the north-west of England

THE Australian National Research Council has elected Sir Thomas Lyle, formerly professor of natural philosophy in the University of Melbourne, to the office of president in succession to the late Mr R H Cambage

AT the meeting of the London Mathematical Society on Thursday, May 16, at 5 P M at Burlington House, Prof C G Darwin, of Edinburgh, will deliver a lecture on "The Refraction and Scattering of Light" Members of other scientific societies who may be interested are invited to attend

SIR OLIVER LODGE is to deliver the nineteenth annual May Lecture before the Institute of Metals on Tuesday, May 7 The title of the lecture will be "Some Ideas about Metals" Cards of invitation to the lecture can be obtained by sending a stamped and addressed envelope to the secretary of the Institute of Metals, 36 Victoria Street, London, S W 1

IT is announced in *Science* that Prof Frank Schlesinger, director of the Yale University Observatory, has been awarded the Bruce Medal of the Astronomical Society of the Pacific for his work on photographic parallaxes and in other departments of astronomy The medal is awarded on the recommendation of the directors of the Harvard Observatory, Lick Observatory, Yerkes Observatory, the Observatory of Berlin, the Observatory of Greenwich, and the Observatory of Paris

THE Council of the Institution of Automobile Engineers has awarded the medal of the Institution to Capt J S Irving in appreciation of his brilliant work in connexion with the design of the "Golden Arrow," which, coupled with the courage and skill of Major Segrave, has resulted in the world's speed record being once more held by Britain, and this time by a very large margin The medal was established in 1922 as a recognition of technical achievement likely to have special influence on the advancement of automobile engineering

THE annual congress of the South Eastern Union of Scientific Societies will be held at the Royal Pavilion, Brighton, from Wednesday, June 5, until Saturday, June 8, inclusive, by invitation of the Brighton and Hove Natural History and Philosophical Society, and the Worshipful the Mayor and Corporation of Brighton Sir Arthur Keith has consented to serve as president in succession to Sir Martin Conway The honorary general secretary of the Congress is Mr E A Martin, 10 Avenue Road, South Norwood, S E 25, and the assistant hon secretary is Mr R W Strickland, 5/6 Clements Inn, W C 2

WE learn from a *Daily Science News Bulletin* (Science Service, Washington, D C) that the United States Senate has passed a bill providing pensions of 125 dollars per month for the Army officers and enlisted men, or their widows or heirs, who took part in 1900 in the yellow fever investigations carried out in Cuba under Major Walter Reed, which demonstrated conclusively that yellow fever is not infectious or contagious in the ordinary sense Further, the names of the 22 men (of whom 14 survive) of the expedition are to be published annually in the Army Register as a roll of honour, and each of the men or their heirs is to be presented with a commemorative gold medal

AT the annual general meeting of the Physical Society of London, held on Mar 22, the following officers were elected —*President* Dr W H Eccles, *Vice Presidents* Sir Oliver J Lodge, Sir Richard Glazebrook, Prof H L Callendar, Sir Arthur Schuster, Sir J J Thomson, Prof C Vernon Boys, Prof C H Lees, Sir William Bragg, Dr Alexander Russell, Dr F E Smith, Prof O W Richardson, Mr R W Paul, Dr J S G Thomas, Prof A O Rankine, and Prof F L Hopwood, *Hon Secretaries* Dr Ezer Griffiths and Dr Allan Ferguson, *Foreign Secretary* Prof O W Richardson, *Hon Treasurer* Mr R S Whipple, *Librarian* Mr J H Brinkworth

A PRIZE consisting of a medal and the sum of £500 is offered by the British Empire Cancer Campaign to the person, or group of persons, who shall submit the essay embodying the results of original investigations which, in the opinion of the judges, is the best contribution towards the early diagnosis of cancer The competition is open to British subjects of either sex, resident in the British Empire or the Dominions, who can obtain a copy of the rules and regulations relating to the prize by writing to the secretary of the British Empire Cancer Campaign, 19 Berkeley Street, W 1 The latest date for the receipt of essays is Dec 31, 1931 The award will be made early in the following year

AN interesting article by Prof Luigi Devoto on the results which have followed the institution of 'summer

time' appears in the *Rendiconti* of the Royal Lombardy Scientific and Literary Institute for last year This question was discussed at the seventh Italian National Congress of Industrial Medicine, held at Parma, following a paper by Prof Gaetano Pieraccini, who considered more particularly its hygienic aspects Pieraccini's conclusions, given *in extenso*, indicate whole hearted accord with daylight saving, which has resulted in the checking of various maladies favoured either by lack of light or by the use of artificial illumination

A catalogue (No 8) of miscellaneous second hand books of science, mainly of botanical and zoological interest, has been received from Mr J H Knowles, 92 Solon Road, S W 2

Readers interested in West Africa may like to have their attention directed to a short catalogue of second hand books relating to that part of the world which has recently been issued by Messrs Francis Edwards, Ltd, 83 High Street, Marylebone, W 1

Applications are invited for the following appointments, on or before the dates mentioned —A senior curator of the Museum of St Bartholomew's Medical College—The Dean of the Medical College, St Bartholomew's Hospital, E C 1 (April 29) A research studentship at St Mary's Hospital Institute of Pathology and Research—The Secretary, Institute of Pathology and Research, St Mary's Hospital, Paddington, W 2 (April 30) A lecturer in engineering, with special qualifications on the electrical side, at the Plymouth and Devonport Technical College—The Secretary for Education, Rowe Street, Plymouth (May 4) A junior scientific officer in the Admiralty Scientific Pool—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (May 4) A lecturer in engineering at the Widnes Municipal Technical College —The Clerk to the Governors, Town Hall, Widnes (May 6) A male assistant at the Low Temperature Research Station, Cambridge—The Superintendent, Low Temperature Research Station, Cambridge (May 6) An inspector of weights and measures under the Surrey County Council—The Clerk of the Surrey County Council, Public Control Department, County Hall, Kingston upon Thames (May 6) A first assistant in the Clinical Laboratory of the Manchester Royal Infirmary—The Gen Supt and Secretary, Royal Infirmary, Manchester (May 8) A pathologist and bacteriologist at the Northern Infirmary, Inverness — The Hon Secretary, Northern Infirmary, Inverness (May 8) The Anderson lectureship in comparative psychology in the University of Aberdeen — The Secretary, University, Aberdeen (May 28) A professor of anatomy at St Bartholomew's Hospital Medical College —The Academic Registrar, University of London, S W 7 (May 30) A professor of mathematics at Canterbury College, New Zealand—The High Commissioner for New Zealand, 415 Strand, W C 2 (July 31) A junior assistant under the Directorate of Metallurgical Research, Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S E 18 A senior biology master at the Cambridge and County High School for Boys—The Education Secretary, County Hall, Cambridge A full time teacher of electrical engineering at the Barnsley Mining and Technical College—The Principal, Harvey Institute, Barnsley A woman biochemist at the Wellcome Physiological Research Laboratories—The Director, Wellcome Physiological Research Laboratories, Beckenham

Our Astronomical Column

Halley's Comet and the Aquarid Meteors of May 2–6 —One of the greatest of English astronomers was Edmund Halley, who acted as Astronomer Royal about two and a half centuries ago Amongst the most important of his achievements was the discovery that a bright comet visible in 1682 and first seen by an assistant of Flamsteed, revolved around the sun in about 76 years and had been observed in the years 1531 and 1607 He predicted its return in 1759, and this was realised

Since Halley's day, further investigations have elicited the fact that the comet has been in existence and visiting the sun during more than 2000 years It was last observed in 1910, and will probably reappear in about 1986 One of the occasions on which it returned was the momentous year 1066 Certain disasters and historical events were formerly connected by superstitious people with its visits

This remarkable object is the largest of all the periodical comets, and it is notable as being the source of a meteoric display which occurs during the first week in May Capt Tupman discovered it about sixty years ago, and it has been reobserved on many occasions since, though it has never furnished a really great abundance of meteors But the objects derived from this comet are unequalled in splendour and length of flight by any other meteoric display in the heavens The earth and comet do not encounter each other centrally, for their orbits at the points of nearest approach are separated by several millions of miles of space The meteors, therefore, which the earth encounters are only those placed on the outer fringe or outskirts of the system Some of the large fireballs belonging to it may possibly be observed in the morning twilight of May 2–6 next, between about 1 A M and 3 A M The conditions prevent their apparition during the earlier hours of the night

Quantitative Analysis of the Sun —Prof H N Russell contributes an interesting article on this subject to the *Scientific American* for April He gives a sketch of various stages in the history of spectroscopy The earliest stage lay in the simple recognition of the presence of various elements in the sun and stars Then followed the stages of the study of radial velocities, and of the detection of magnetic fields. Attention is now being given to the contours of lines—curves indicating the gradations of intensity throughout their widths and deductions as to the density with which the atoms are packed in the course of the ray of light It is stated that the weakest lines on ordinary stellar spectrograms (of intensity 1 on Rowland's scale) could be produced by 2×10^{13} atoms per square centimetre, which is a millionth of the number in a cubic centimetre of air, further, that the whole amount of gas in the sun's atmosphere, if condensed to the density of our air, would form a layer between 10 centimetres and 1 metre in thickness

Research Items

Lovelock Cave.—In 1911, during mining operations for bat guano, numerous ancient Indian objects were discovered in the Lovelock Cave in the Humboldt Valley of West Central Nevada. Further excavations were carried out under more favourable conditions in 1924 by Mr. M. R. Harrington and Mr. Loud, which are now described in a fully illustrated monograph issued as No. 1 of Vol. 25 of the *University of California Publications in American Archæology and Ethnology*. To the description of the recent excavations Mr. Loud adds an account of the objects obtained in 1912. Originally Lovelock Cave was a long shed-like rock shelter about 150 feet in length and 35 feet wide. Earthquakes and other natural agencies caused masses of rock to fall from the roof blocking the opening in front converting it into a cave. The local Indians, the Northern Paiute, have a legend that the inhabitants were Pit River Indians whom they drove out. The cave had undoubtedly been used as a dwelling place, and not solely as a cemetery and place of ceremonial deposit, as has been suggested. The earliest horizon of occupation belongs to the Basket Makers of possibly three to four thousand years ago, with possibly sixty burials in the cave, and as the cave refuse lies directly on the lacustrine deposits it begins possibly within a hundred years of the subsidence of Lake Lahontan. The deposits of human origin show no bones of the sabre tooth tigers, horses, or camels found in the lake shore gravels. The culture of the earliest occupation resembles, but is poorer than, that of the Basket Makers, nor was there any knowledge of agriculture. It resembles the hypothetical 'basic culture' of the south-west. After a deposit of five feet, a foreign influence creeps in, forming a transition period, and finally, as it grows stronger, the bow and arrow appear. Then begins a 'Later Period,' possibly about A.D. 1000, containing many articles which have their counterpart among the modern Paiute. The cave dwellers would thus appear the cultural, if possibly not the linguistic, kinsfolk of the Northern Paiute.

The Australian Aboriginal Brain.—Prof. Woollard (*Jour. Anat.* vol. 63, pt. 2, pp. 207-223) gives an account of four brains of aboriginal Australians. He finds that the aboriginal Australian brain is a small brain, extremely dolichocephalic, in which the insula tends to be exposed and the primitive features in the organisation of the striate area to be retained. His observations offer no ground for supposing that the aboriginal brain discloses any peculiar simian features or that it resembles microcephalic brains of European origin, or that it retains any special features of the fœtal human brain. He finds that the variations in the indices of the aboriginal brain present no peculiar features, and the differences between it and the European brain are adequately accounted for by the extreme dolichocephaly. The proportion of grey to white matter in the hemispheres is the same as in the European brain, and there are no significant differences between the right and left hemispheres. The total weight of the brain and the weights of the hemispheres are smaller than in the European brain.

Nervous Symptoms and Vocational Selection.—In the *Revue de la Science du Travail* (Tome I., No. 1), Dr. Toulouse directs the attention of students of vocational selection to the problem of the nervous person in the industrial world. He maintains that slight nervous troubles are infinitely more common than any one is aware of, and that their action on the output of the worker is disastrous. He contrasts the limited and ascertainable effect on output of an organic disease, with the irregular and incalculable effect of nervous symptoms. There is here no question of the intelligence, which might be of the highest order, but of an emotional or temperamental instability, over which the person has little control, leading to erratic work curves and long sickness absenteeism. He pleads for a greater recognition of this factor by those doing mental testing and for a periodic examination of employés during their industrial career. The nervous condition which in the typist may involve an unusual number of errors may in a signalman lead to a disaster. It is probable that behind an accident is an emotional instability and not a defective sense organ or intellectual weakness. A similar conclusion was reached by the Industrial Fatigue Research Board after an investigation of telegraphist's cramp: it was shown that those who suffered from that disorder, which essentially involved even in the earlier stages a diminished output, were of the temperament popularly called 'nervous'.

Sea Trout in Scottish Waters.—In his paper "Sea trout of the River Ailort and Loch Eilt, Part 2, 1920 and 1925-27. With an Appendix on Ailort Salmon" (Fishery Board for Scotland. Salmon Fisheries, 1928, No. 9), Mr. G. Herbert Nall continues his work based on scale reading, the first part of which was published in 1926. The present part embodies the results obtained by analysing both the old and the new material, a résumé being made of the whole. The sea trout of this district, like most of those of the west coast rivers, have a more uniform type of life than those of the east coast rivers, the chief features in the river Ailort being the big runs, beginning as early as March and mainly composed of fish which have spawned in the previous winter, and the high average size of the fish, a few of which attain a great weight. The size is mainly due to good feeding and favourable conditions both for the parr and the sea fish, giving rise to a vigorous stock. The Ailort fish survive to a greater age and weigh more than do those of the east coast rivers, and maturity is reached rather later. Early spawners seldom survive the tenth year from hatching, whilst amongst those which spawned later in life some exceed fourteen years, and the percentage of survivors rises with the increase in the number of sea years before maturity is attained. Spawning retards growth, but to a less degree than in the salmon. Salmon smolts usually migrate after two years of river life, those of the sea trout after three years. Salmon smolts at migration are about two inches shorter than those of the salmon trout of the same age. During this river life the salmon parr grow more slowly than those of the sea trout, but after migration the growth rate of the salmon is by far the larger. It has often been suggested that some of these large Ailort sea trout are hybrids between salmon and sea trout, but although experiment has proved that salmon eggs can be fertilised by sea trout milt and vice versa, the author is of the opinion that there is no indication of hybridisation between salmon and sea trout, nor are there two or more distinct races of the latter in the Ailort.

Parasites and Predators in Biological Control of Insect Pests.—In the *Bulletin of Entomological Research*, vol. 19, March 1929, Dr. W. R. Thompson discusses this important subject. As he points out, both predaceous and parasitic insects practically always kill their hosts. The question of their relative

value as controlling factors is, however, somewhat obscure That insect predators are numerous and beneficial is generally acknowledged, but that they are as valuable in these respects as parasites is not by any means universally believed This subject is ably discussed by Dr Thompson, who advances theoretical conclusions, partly based upon calculations of the length of time necessary for the annihilation of a given host population by given populations of gregarious parasites, solitary parasites, and predators His theoretical conclusions indicate that the value of predators has been underestimated by practical entomologists, and they are supported by the history of the practical application of biological control As examples, he quotes the efficiency of such predators as Coccinellidæ in controlling certain scale insects and mealy bugs the utilisation of the carabid beetle *Calosoma* in controlling the gipsy moth in New England and the extraordinarily valuable results attained by the introduction of the capsid, *Cyrtorhinus mundulus*, in controlling the sugar cane leafhopper in the Hawaiian Islands He concludes that predators are worthy of more careful attention than has so far been accorded them, but that the relative values of parasites versus predators in any given case can only be decided by critical investigation in the field

PRE CAMBRIAN LIFE —Some months ago it was announced in the daily Press that a pre Cambrian fauna had been discovered in South Australia Some details of this have now been given by Sir T W Edgeworth David in "Notes on newly discovered fossils in the Adelaide Series (Lipalian ?), South Australia" (*Trans Roy Soc S Australia*, 52, pp 191 209, pls xiii xviii, 1928) He considers that he has found the remains of Algæ, polychætous annelids, brachiopods, and eurypterids in the Adelaide Series at horizons ranging from 2000 to 12,000 feet below the oldest rocks in which undoubted Lower Cambrian fossils have been traced The age may be (1) basal Lower Cambrian *or* (2) Lipalian, that is, belonging to the time represented in North America by the unconformity between the Keeweenawan and the base of the Cambrian, *or* (3) Proterozoic (Algonkian) Without seeing the specimens on which Sir Edgeworth David's views are based, it is almost impossible to express an opinion as to their nature The figures which he gives are not convincing If he has really found eurypterids in beds of pre Cambrian age, it is difficult to account for the fact that scarcely any undoubted representatives of that group of arthropods have been discovered in the Cambrian

TROPICAL AGRICULTURE —The Imperial College of Tropical Agriculture, Trinidad, has issued its report for 1927–1928 together with the prospectus for 1929–1930 Developments have been made in all directions, and further extensions are hoped for in the near future An estate is specially needed for research, principally into biological problems, as the existing grounds are required for the instruction and training of students The power station is now in use and the new building for low temperature research and cold storage is completed, although the interior fittings of the latter are not yet finished The construction of a new chemical block is proceeding, and alterations and additions have been made in the sugar factory In research work good progress has been made With regard to bananas, the main objects are to secure good marketable varieties immune from Panama disease (a problem which necessitates a study from both the pathological and physiological point of view), and further to investigate the ripening process in order that the fruit may be successfully marketed overseas The new cold storage chamber will prove of special benefit in these problems Soil research with reference to the sugar cane crop has been successfully carried out The lime content of the soil, and particularly the proportion of adsorbed calcium ions, has been shown to be correlated with the resistance of the plant to froghopper blight A practical outcome of this work is that the College is now able to advise growers as to the amount and kind of lime to apply to their fields and the methods of application to employ On the other hand, insecticide work has also proved successful, and the froghopper pest can now be kept under control if the proper executive arrangements are made at the right time, the cane growers acting collectively The main objects of research in the coming year are problems dealing with tropical fruits such as bananas and citrus, biological investigations of cacao, and genetical and fertiliser trials with sugar cane

ISO ELECTRIC POINT OF CELLS AND TISSUES —In a recent number of *Biological Reviews* (4, p 1) H Pfeiffer has contributed a comprehensive review of the now voluminous literature bearing on this subject, in which he points out that the original conceptions of the iso electric point (IEP) are tending to develop both in physical chemistry and in biology Cells and tissues of plants, and perhaps of animals, show many analogies with ampholytes, probably owing to the presence of these substances at the cell surfaces and at the internal boundaries of the protoplasm From the observed effects, attempts have been made to determine the IEP in the case of a given tissue, and also to explain the regulatory effects of the cells upon external solutions Pfeiffer points out that most biological work has been concerned not with the *true* IEP, which is given by the stationary phase in electro cataphoresis, but with the *apparent* IEP (as found, for example, from minima of swelling, viscosity, and osmotic pressure), which depends primarily on the reaction at which there is a maximum of neutral molecules The apparent IEP determined in this way may be displaced owing to salt formation, and this is particularly likely to happen in the case of protoplasmic ampholytes Further, the presence of two or more ampholytes in protoplasm does not, on present conceptions, necessarily lead to the establishment of a collective IEP as it may tend to do *in vitro* There may, in cases known, be signs of a number of apparent iso electric points The relation of the apparent IEP to growth and physiological functions of the organism is discussed, and the author emphasises the view that further work is required on the effect of these phenomena on ion movement and the electro histological behaviour of protoplasm, and on the mechanism of such functions as protoplasmic streaming

CYCLONES AT MAURITIUS —Mr R A Watson, Director of the Royal Alfred Observatory, Mauritius, is to be congratulated for producing "The Cyclone Season 1927–8 at Mauritius," which is to be the first of an annual series of publications summarising the information collected at that Observatory about the cyclones occurring in the neighbourhood during each cyclone season The cyclone season in Mauritius extends normally from November to May, the one under discussion was one of the stormiest on record, and was remarkable also for the fact that the tracks were farther west than usual, to which peculiarity the absence of gales at Mauritius itself is to be referred The weather reports from neighbouring islands were supplemented by information supplied by ships calling at the island In two instances enough observations were available to allow of the construction of diagrammatic systems of wind arrows in which the wind represented is the wind relative to the moving centre, the isobars being shown in the usual way It is interesting to

find some evidence of a discontinuity of wind along the actual track in front of the centre and not as was found by Cline in the case of West Indian hurricanes (NATURE Dec 24 1927 p 909) between the winds of the two quadrants on one side of the track Allowing for the reversal of the circulation as between storms of the northern and southern hemispheres the analogue for Mauriti is of the right rear and right front quadrants between which the discontinuity was found by Cline would be the left rear and left front quadrants These diagrams are of interest also in that they show some flattening of the isobars in a direction parallel with that of the track and constitute additional evidence of a lack of that symmetry of wind circulation usually attributed to the tropical cyclone in meteorological text books

THE AURORA —The investigation of conditions in the upper air which has been made by E O Hulburt and H B Maris in connexion with their theory of the aurora and of magnetic storms (*Physical Review* vol 33 pp 412 431 see also NATURE Nov 24 1928 p 807) is remarkable for the importance which is attached to the influence of the ultra violet radiation from the sun The wave lengths which are absorbed at heights above about 450 kilometres are supposed to produce indirectly by processes of excitation and ionisation a kind of spray of highly rarefied matter which extends outwards for upwards of forty thousand kilometres Collisions are very infrequent at the low pressures involved and the molecules can describe practically free orbits in the earth s gravitational field If one is ionised by further absorption of ultra violet light both the liberated electron and the residual positive ion will return to the lower air in helical paths the axes of which are determined by the earth s magnetic lines The aurora is associated with the downward currents and its distribution over the surface of the earth can be predicted immediately from the magnetic field of the latter This theory which has been developed on quantitative lines seems to account adequately for the main phenomena both of auroræ and of the complicated changes which occur in the magnetic elements during a magnetic storm and the greatest difficulty in its further development is likely to arise from incomplete knowledge of the precise nature of the atomic processes of excitation and ionisation The authors mention incidentally that good direct short wave communication was maintained between the U S Naval Research Laboratory at Washington and the Byrd Antarctic expedition

EFFECT OF HEAT ON THE SENSITIVITY OF PHOTOGRAPHIC PLATES —The results of an investigation of the effect of heat on the sensitivity of photographic plates are described in two papers by O Masaki in the *Memoirs of the College of Science Kyoto* Series A vol 12 No 1 It was found that the sensitivity of panchromatic and other slow emulsion plates increased with rise of temperature the sensitisation being greatest towards the red part of the spectrum In the case of high speed plates rise of temperature produced a decrease in sensitivity especially in the violet region For all kinds of plates heating increased the contrast and in panchromatic and orthochromatic plates this change was particularly marked for rays of long wave lengths The sensitising action of heat was retained for some hours after the temperature had been reduced to normal and was much greater than that produced by mere drying of the plates An expression giving the relation between the density of the developed image and temperature was obtained and holds from 10° C to 80° C

FLAME AND SPARK SPECTRA FROM SALT SOLUTIONS —In the *Chemiker Zeitung* of Mar 16 Dr W Hirschel describes some quantitative results which he has obtained with the apparatus first described by him in 1916 in which minute amounts of salt solutions are pulverised by means of a spark before being introduced into the Bunsen flame The resulting flame can be maintained for an hour with the consumption of only a few milligrams of salt and the flame is so intense that its spectrum can easily be photographed The apparatus has hitherto been used for the visual examination of spark spectra but it has now been found possible to photograph the latter This has necessitated the use of much stronger sparks than were possible in the original apparatus A device for cooling the anode with cold water has been introduced and instead of a large induction coil and battery of cells a simple Wehnelt Simon Caldwell interrupter is used with an alternating current at 115 220 volts and a small coil

ATOMIC WEIGHT OF COPPER —A communication by T W Richards and A W Phillips in the February number of the *Journal of the American Chemical Society* describes experiments on the atomic weight of copper from different sources No difference was found in the atomic weights of specimens of copper from mines in the Lake Superior region and from Chile The ratio of the atomic weights of copper and silver was found by analysis of pure cupric chloride On the basis of Ag = 107 880 the atomic weight of copper was found to be 63 557 Copper is known to have at least two isotopes and its atomic weight was in need of confirmation The Lake Superior material was not later than Cambrian that from Chile was from lodes intrusive in Jurassic strata

SIZE LIMITS OF TURBO GENERATORS —During the last few years there has been a remarkable increase in the size of the turbo generators used in electric power stations The size of the machines which run at 25 revolutions per second is now only limited by the transport facilities available to their destination The desirable size of the machines which run at the standard speed of 50 revolutions per second is about 60 000 kilovolt amperes at the present time but in a few years machines of double this capacity will probably be running The uncertain factors are the strength of the forgings forming the rotating part and whether the journals for such heavy machines would be safe The centrifugal forces and the consequent enormous stresses in the rotating parts at these high speeds make it necessary to use only forgings of the greatest mechanical strength In a paper read by J A Kuyser to the Institution of Electrical Engineers on Mar 21 it was stated that a steel containing about 2 per cent nickel with a very small percentage of chromium when properly annealed has the necessary tensile strength On the Continent the alloy used for high speed machines has a much larger percentage of nickel and chromium and is hardened in oil However experiments carried out by Metropolitan Vickers led to the conclusion that the oil hardening of this steel produces a high radial stress which when the machine is running is added to the centrifugal stress A significant fact is that on the Continent during the last three years there have been four explosions with several fatalities of high speed machinery made of this steel It was stated that several of the older types of machines are operating with parts of their core at 200° C These high temperatures cause relative displacements of the copper and the mica insulation, as the temperature coefficient of copper is 50 per cent greater than that of mica

Mimicry

By Dr G D HALE CARPENTER, Entebbe, Uganda

THE phenomena of mimicry, by which is meant the deceptive resemblance of one creature to another, were first made known among butterflies, and it is natural that the subject should have been further investigated in the same group of insects But it has suffered thereby, for the narrowing of the field of inquiry has resulted in attempts to account for the phenomena which do not bear criticism in the light of wider knowledge and more detailed investigations into geographical distribution

Mimetic resemblances are undoubtedly most convincingly explained as the result of the operation of natural selection upon such variations as may be produced from time to time We may in this connexion quote the words in which Darwin, writing to Asa Gray, expressed his confidence in natural selection as the motive cause of evolution "I cannot possibly believe that a false theory would explain so many classes of facts as I think it certainly does explain On these grounds I drop my anchor, and believe that the difficulties will slowly disappear "

Since H W Bates first published his memoir on mimicry in 1862 an immense number of field observations have been recorded and a large amount of work has been expended upon museum specimens, but the theory of natural selection still offers the most convincing explanation of the facts

Attempts have been made to account for mimetic resemblances by the similar results produced by climatic or other external influences upon different species in the same locality, and such an explanation is given by Prof E W MacBride in his essay on "Zoology," p 211, in the collection of papers published in 1925 by Messrs Blackie and Son under the the title of "Evolution in the Light of Modern Knowledge"

Prof MacBride observes "We have given to our readers strong reasons for disbelieving altogether in random variations, and therefore what we have to explain is why evolution has set in such a direction as to cause these insects to resemble one another Now, Eimer has shown that the changes in coloration which the mimic is supposed to have undergone, in order to increase its resemblance to the model, are of a kind which supervene independently in all families of butterflies and moths as *a reaction to climatic conditions* These changes take place in some families more quickly than in others, and what happens in real 'mimicry' is apparently that individuals which have reached a certain stage in this process are favoured by natural selection "

Mimetic resemblance is thus believed to have been caused by an inherited response to environmental influences "Just as in the formation of habit the action becomes easier with every repetition, so as the generations succeed each other the response to the same environment becomes more readily called forth" Prof MacBride alludes later to "the vast sea of facts which tell in favour of habit as being the prime cause of evolution" He acknowledges the unsatisfactory nature of this as an explanation of mimicry, how unsatisfactory it is and how completely it fails to account for recently discovered facts it is the purpose of this article to show

Let us first consider some examples from among the butterflies alone, as this explanation was founded on a study of their patterns

1 The effects of intrusion of a foreign species upon the indigenous inhabitants

(*a*) A very good example is that of the 'Monarch,' a Danaine butterfly belonging to an Asiatic group which invaded North America in comparatively recent times, and is there mimicked by an indigenous butterfly, the 'Viceroy,' closely related to our 'White Admirals' of Europe Clearly, if these resemblances are the result of local climates, the 'Monarch' ought to have mimicked the 'Viceroy'!

(*b*) Again, in the eastern Fijian islands a group of Euploeine butterflies is characterised by a dark ground colour with a feeble or obsolete white marginal pattern, while the same species are represented in the western islands of the group by forms with a strongly marked pattern Prof E B Poulton has suggested that these facts are to be explained by an earlier invasion of Fiji by the dark Euplœas and a later powerful invasion by a strongly patterned *Euplœa*, which has reached the western islands in numbers and has become the model mimicked by the older darker species

2 The phenomena of mimicry, even among butterflies, cannot be disposed of so easily as Eimer's explanation suggests, they are much too complicated The study of geographical races is all important in this connexion

(*a*) A typically aposematic or warningly coloured species of the Acræine genus *Planema* (*P epæa*) has in West Africa a black and orange male and black and white female In the Uganda race *epæa paragea*, however, the sexual dimorphism disappears and the coloration of both male and female is grey brown with a pattern of cream-colour Both these races are mimicked by the females of *Papilio cynorta*, which in West Africa resemble the black and white females of *epæa*, and in Uganda both sexes of *epæa paragea* The *Papilio* male retains the same appearance in both areas On the other hand, a Nymphaline butterfly in Uganda, *Pseudacræa eurytus*, allied to our 'White Admirals,' has developed a form *obscura* in which both sexes mimic *epæa paragea* Climate, according to Eimer's hypothesis, has caused one sex of the *Papilio* to resemble the model but both sexes of the Nymphaline This, however, is far from the end of the story *Pseudacræa eurytus* occurs all over tropical and subtropical Africa in a bewildering variety of forms, sometimes with sexes alike, as in the form *obscura*, sometimes unlike Wherever these *Pseudacræas* occur they are mimetic of the local species of *Planema*, sex resembling sex when the sexes of the model are unlike But in Uganda some of the *Planema* models, such as *epæa paragea*, have the sexes alike, while in others they are different, and the local forms of *eurytus* mimic both types Hence in the same area, and therefore subject to the same climatic influence, most surprisingly complicated and contrasted results have been developed It may be argued that equally complicated results have arisen among the models in the same area, but there is this essential difference—the Planemas are of entirely different species, whereas the mimetic forms of *eurytus* belong to a single species, so that mimics with sexes different and with sexes alike form a single interbreeding community and may appear side by side in a single family

(*b*) Equally difficult to explain by Eimer's theory are the intricate mimetic resemblances between members of the fine genus *Charaxes* Some of the larger species which act as models for the smaller are themselves mimics of other large species, and one sex of a species may be a mimic while the other is a model Yet another species (*etheocles*) has a non

mimetic male which varies little, but the females occur in strikingly different forms which mimic the males, others the females, and others again both males and females of larger species

3 Explanations of mimicry are too often based on consideration of colour and pattern alone Any naturalist familiar with mimetic resemblances in the field has found by practical experience that colour and pattern are only part of the factors which make up the deception, behaviour is of great importance Even among butterflies themselves the difference of behaviour between models and some mimics is characteristic, if the mimic belongs to a family less well protected than the model For example, the Acræine models of the genus *Planema* can often be picked from flowers by the fingers, while the mimetic forms of *Pseudacræa eurytus* are shy, and require to be approached with caution if they are to be caught If frightened they dash away, whereas the *Planema* will only flutter just out of reach and often boldly return to the same spot

Even if it be admitted that the action of climatic conditions is effective in causing different species of insects to develop the same variations in coloration, it cannot be held to explain instances of mimicry drawn from a much wider field than that from which Eimer drew his examples How could the likeness of certain spiders to ants be put down to this cause? Many instances have been recorded where the mimicry has completely deceived experienced field naturalists Climate in this case must be supposed to have altered profoundly the characteristic shape of spiders so as to produce the 'waisted' effect of an ant, to have altered gait in such a way that one pair of legs is not used for progression but is held up in the air and waved about to resemble the sensitive antennæ of an ant, and even, in certain spiders, to have suppressed, except in very special circumstances, the habit of jumping that is characteristic of the family to which most ant like spiders belong

Spiders, having no metamorphosis, are generally exposed to similar conditions at all stages of their existence Insects which undergo complete metamorphosis are exposed to conditions during their immature stages which often differ as completely as possible from those to which the adult stages are exposed The close resemblances often found between adult insects cannot possibly be explained as due to the action of absolutely dissimilar conditions upon their respective larvæ For example, the mimetic resemblance of the common drone fly to the hive bee deceives even a monkey, as I have found by experiment in Africa The larva of the fly lives in mud and foul fluids among which it feeds in the open, freely exposed to changes of light, temperature, and oxygenation The bee's grub is enclosed in a small cell in the hive, among surroundings as uniform as the bees can make them, feeding on food supremely different from that of the fly's larva Malacoderm beetles of the family *Lycidæ* all over the tropics are mimicked extensively by insects of such diverse habits, and feeding in such different ways as larvæ and adults, that no explanation based on the influence of external circumstances can account for the well known mimicry of these conspicuous beetles, which have been abundantly proved to be distasteful to birds and other animals

4 Mimics differ from their models not only in behaviour but also in other respects A typically aposematic insect such as an Acræine or Danaine butterfly, or a Lycid beetle, is of an extremely tough physique It will be uninjured by treatment which would break the wings of another butterfly such as the Nymphaline or Papilionine mimic, and it will also resist the poisonous fumes of a cyanide bottle to a surprising extent This resistance to injury is part and parcel of the process whereby an aposematic insect teaches an enemy that it is harmful or unpalatable It almost invites attack, and if it is seized and handled, suffers little injury, and when released after a pinch or a lick is often undamaged This difference in physique and temperament, coupled with similarity of superficial appearance, is difficult to explain by climatic action

5 Another class of facts telling against the argument now discussed is the production of the same effect in a variety of ways The thin 'waists' of Hymenopterous insects are frequently mimicked in stout bodied insects of other orders by either white colour or dense white pubescence which at a little distance effectively 'paints out' part of the body, leaving only a thin waist visible

6 It is usually found that mimetic resemblance only goes so far as is necessary to produce a *superficial* deceitful appearance, often the characteristic appearance of the group to which the mimic belongs may be found in or on parts which do not interfere with the mimetic resemblance

The antennæ of beetles which mimic other beetles might often be a hindrance, for whereas in the mimic the characteristic antennæ of its family may be long and thin, the antennæ of the distasteful model may be short and stout This difficulty is surmounted in the mimic by a thickening of the antennæ for a distance approximately equal to that of the thick antennæ of the model, the remaining segments of the long antennæ being thin and relatively inconspicuous The influence of external circumstances must here be very patchy!

7 Such examples of mimicry as the resemblance of large Sphingid caterpillars to some terrifying reptile with large eyes can scarcely be explained by the influence of climate

8 It is somewhat difficult to understand why the explanation of mimicry by the action of natural selection has been a stumbling block to many The fact that many insects escape their enemies by minutely resembling objects that are of no interest to them, such as a bird dropping, is usually accepted as an example of the working of natural selection Yet when the object that is of no or relatively little interest to the insectivorous creature is another insect, it has been claimed by some writers that natural selection cannot be the agent which has effected the resemblance Mimetic resemblances, as was long ago shown by Prof Poulton, are only one example of various types of deceitful resemblance Natural selection will account for them all as well as for the examples of conspicuous 'warning' colours Why, then, should it be thought necessary to invoke an explanation for one set of resemblances which is supposed to be powerless to account for others?

9 Prof MacBride, in the article alluded to earlier, remarks that "it is assumed, often on very insufficient evidence, that the one of the two animals which is the commoner (*i e* the model) has some peculiar feature which makes it dangerous to the animals which would attack it, and that these learn to recognise it and avoid it"

It is true that when the theory of mimicry was first propounded there *was* very little direct evidence, but critics of the theory often seem to be unaware of the body of experimental and observational evidence that has been accumulated during recent years in the publications of the Entomological Society and others

It is sometimes a stumbling block to critics that insects which are supposed to act as models have been seen to be devoured freely by certain enemies For

example, I have myself obtained evidence that ants are a very important element in the food of Agamid lizards, and Danaine butterflies have been seen to be devoured by certain birds In this connexion the old adage should be remembered, "One man's meat is another man's poison" It is important also to remember that not even the most enthusiastic supporter of mimicry claims that models are at all times and in all circumstances exempt from being devoured I have seen the foul smelling and evil looking black 'Devil's coach horse' beetle pulled out from among dead leaves by a wren in a wood and devoured in mid winter Edibility is entirely a question of the relative abundance of food it is not without significance that mimetic resemblances reach their highest development in those parts of the world where insect life is most abundant

10 Another stumbling block may be given in Prof MacBride's words "It is held that the predatory animals mistake the defenceless species for the dangerous one, and that so the defenceless one escapes"

I do not think it is necessary to suppose this all that is required for the protection of *B* is that it should sufficiently resemble *A* to remind the enemy of an unpleasant experience connected with an attempt to eat *A* When food is abundant a very slight degree of resemblance to a creature known by previous experience to be unpleasant may save the life of another This is within the bounds of human experience Many people intensely dislike worms "because they wriggle so" Why should a wriggling movement be more unpleasant than, for example, the sudden leaping of a frog? Surely, because of man's origin, in countries where an instinctive dread of a snake was a criterion of life and death It is not that we think worms *are* snakes, but they remind us of them This point of view makes it much easier to understand cases where a mimic is much larger or smaller than its model, or where the resemblance is very elementary, or even depends but little upon colour but rather upon some trick of movement or posture

In all such cases there is nothing in the theory of mimicry produced by selection of variations to prevent further improvement of the resemblances, nor on the other hand, is there any reason why a slight degree of resemblance *must* be perfected, all that is necessary is that the resemblance should remind an enemy of some previous unfortunate or unpleasing experience Thus perfect and imperfect mimetic resemblances may exist together

11 Finally, I would allude to the wonderful deceptive resemblances of the eggs of cuckoos to those of the nest in which they are placed [1] In this case the enemy is the parent of the eggs resembled, which are the models The phenomena are analogous to mimicry, there is a resemblance to something which the enemy will not attack, one theory will explain the evolution of both these classes of deceptive likeness Can it possibly be claimed that these minutely detailed resemblances between eggs of birds are of a kind which supervene independently in the eggs of cuckoos and host birds as a reaction to climatic conditions? The answer is surely, 'No' and the same answer may be given to the claim that "What happens in real 'mimicry' is apparently that individuals which have reached a certain stage in a reaction to climatic conditions are favoured by natural selection"

[1] See the papers by E C Stuart Baker *Proc Zool Soc*, 1923 p 277 and F C R Jourdain *ibid* 1925 p 639 See also presidential address to Ent Soc Lond, Jan 20 1926 by Prof E B Poulton

Diamond Jubilee of the Iron and Steel Institute

THE May meeting of the Iron and Steel Institute to be held this year on May 2 and 3 is of special significance inasmuch as the Institute is celebrating its diamond jubilee The proposal for the formation of the Institute originated at a meeting of the Northern Iron Trade, held at Newcastle on Tyne on Sept 29, 1868, and a committee was appointed with the object of giving effect to this suggestion Mr Isaac Lowthian Bell (as he then was) took a prominent part in the proceedings from the very beginning, and it was largely through his influence and efforts that the Institute took shape

A provisional meeting was held in London in February 1869, at which the Institute was formally constituted, the Duke of Devonshire consenting to accept the position of president for the first two years The inaugural meeting was held on June 23, 1869, in the Hall of the Society of Arts, when the noble president delivered a most interesting inaugural address, in which he traced the development of iron and steel manufacture The next meeting of the Institute was held at Middlesbrough on Sept 22 and 23 of that year, the first paper, appropriately enough, being by Mr Isaac Lowthian Bell

The Institute was by this time fairly formed, the first secretary being Mr J Jones and the first treasurer Mr (afterwards Sir) David Dale At the end of that year the Institute numbered 292 members, to day the membership is just over 2700, and this numerical increase is good evidence that the work of the Institute has met a real need in the iron and steel industry The object of this, as indeed of all similar technical societies, could scarcely be better stated than it was by the president in his inaugural address, when he declared the object of the Institute to be "the promotion of science in its practical applications rather than in its purely intellectual aspects," and it may fairly be said that this principle has been the dominating principle of the Institute

The jubilee of the foundation of the Institute was celebrated by a banquet in the Guildhall on the evening of May 8 1919, at which the then president of the Institute Mr Eugene Schneider, of the famous Creusot Works, presided supported by a very distinguished company As was not unnatural in the spring of 1919, the conclusion of the War was the thought uppermost in men's minds and this fact so overshadowed the fact that this was the jubilee meeting of the Iron and Steel Institute that relatively little attention was paid to the fact that the Institute had then attained its half centenary of existence On this account the celebration of the diamond jubilee this year is likely to assume an even greater importance than it otherwise would

It is interesting to note that there are still three members whose membership dates from the inaugural meeting of the Institute in London, namely, Sir Hugh Bell, Bart, himself a past president and a Bessemer medallist, who joined the Institute at the same time as his father the late Sir Isaac Lowthian Bell, Bart, who, as already pointed out took a prominent part in the formation of the Institute, Mr J J Bleckly, of the Pearson and Knowles Coal and Iron Co, Ltd, and Mr John Neilson, a nephew of the late James Beaumont Neilson, the inventor of the hot blast, which practically revolutionised the blast furnace practice of the world The Institute can fairly claim to have counted among its list of members every one of the men who have been distinguished in the iron and steel industry for the last sixty years, and

the history of that industry and of its wonderful development is to be found in the *Journal* of the Iron and Steel Institute

No one can doubt that the Institute will continue to go forward and prosper along the same lines traced out for it by its founders, which it has so consistently followed throughout the whole sixty years of its existence, and it seems almost superfluous to wish for a continuance of its prosperity for many years to come This wish will indeed be fervently re echoed by everyone in Great Britain, seeing that the prosperity of the Iron and Steel Institute is bound up with the prosperity of the iron and steel industry, which in its turn is the foundation of the prosperity of the nation

The Stone Age in South-Eastern Asia

RECENT research appears to point to more or less uniformity in the characteristics of the stone age cultures of south-eastern Asia Investigations in French Indo China by MM Mansuy and Patte and Mlle Colani in the caves near the Bac Son massif (Tonkin) yielded a large number of implements which these investigators regarded as relics of the oldest known stone age of Indo China, classifying them as lower neolithic Cord marked pottery was also found, but regarded as belonging to a later phase of the neolithic Evidence of similar stone age industries has been found in kitchen middens about twenty kilometres from Medan in the east coast province of Sumatra, and on the plains and lower hills of this province at sites always on the banks of rivers

In the *Journal of the Federated Malay States Museums*, vol 12, Part 6, Mr I H N Evans reviews this material critically in relation to the results of recent excavations in caves in Perak The hypothesis of the French archæologists is that an early neolithic people, using roughly chipped implements only, came into contact with a people using polished implements, and from them adopted the practice of polishing the edges of their implements Mr Evans, however, regards the chipped implements as a truly older palæolithic culture, surviving in association with the forms with polished edges which are proto neoliths, the latter developing more and more to become a high neolithic culture In Sumatra, iron weapons of a type still in use in north Sumatra in a layer immediately above that containing bouchers, with no sign of transition, pointed to a very late survival of a palæo lithic culture

In Perak, Mr Evans, excavating with Dr P U Van Stein Callenfels, of the Archæological Service of the Netherlands Indies, who carried out the investigations in Sumatra, found similar stone age cultures in caves near Lenggong (Upper Perak) and Padang Rengas (Kuala Kangsar) In the latter area the rock shelter, Gua Kĕrbau, contained human remains at a depth of 3 18 metres and below Shellfish formed a large part of the diet of the inhabitants throughout the occupa tion Flakes and chips occurred throughout, but the first palæolith was found in deposit *B*, the most common type being the *coup de poing* of almond shape The first fragment of a proto neolith occurred in layer *D* at a depth of 2 40 metres The lowest was found at 5 74 metres The proto neoliths showed different stages of development One might be classified as a middle neolith Grinding stones, grinding slabs, shells, some clearly, others probably, for use as amulets, and pottery in the upper layer were found

Certain conclusions are offered tentatively Palæo liths, so called Sumatra types, and proto neoliths, are associated throughout, cord marked pottery belongs to the later stages of palæo proto neolithic culture, the makers of proto neoliths had older types of the neolithic culture as examples, and a palæolithic civilisation making use of 'Sumatra type' implements spread at a certain period over south-east Asia, reach ing even Sumatra, while the palæo proto neolithic stage also spread over the same area but did not reach Sumatra

University and Educational Intelligence.

LEEDS —The site is now being cleared for the new block for the Physics Department The accommoda tion will include two large laboratories, each about 5000 square feet in area, and a smaller laboratory for honours students, three lecture theatres for 250, 150, and 80 students respectively, and about thirty other rooms, the whole occupying a block about 100 feet square and comprising a basement and three floors over The building is estimated to cost about £47,400

LONDON —Notice is given that applications for grants from the Thomas Smythe Hughes Fund for assisting medical research must reach the Academic Registrar, South Kensington, S W 7, by, at latest, June 15

ST ANDREWS —At a meeting of the University Court on April 19, it was intimated that Provost W Norman Boase, St Andrews, had gifted to the United College the endowment fund for the institution of a residential entrance scholarship of £100 a year, tenable for three or four years by an entrant student resident in one of the residential halls of the United College, on conditions similar to those prescribed in the case of the Harkness, Russell, and Patrick Hamilton Entrance Scholarships As the Patrick Hamilton Scholarship was instituted in commemora tion of the quater centenary of Patrick Hamilton, the Martyr, a former student of the University, so the new scholarship is to be named the Montrose Scholarship in commemoration of the tercentenary of the studentship at St Salvator's College of the great Marquis of Montrose

APPLICATIONS for grants from the Dixon Fund of the University of London, for assistance in scientific investigations, must reach the Academic Registrar of the University, South Kensington, S W 7, before May 15

A BUSK Studentship in aeronautics, of the value of about £150 and tenable for one year from Oct 1 next for research in aeronautics and specially in stability problems, is being offered Forms of application, returnable not later than May 12, can be obtained from Prof B Melvill Jones, Engineering Laboratory, Cambridge

A FELLOWSHIP of the value of £300 per annum for research on petroleum problems is being offered by the Institution of Petroleum Technologists The fellow ship will be tenable for one year, with a possible re newal for a further year Forms of application (returnable by June 1 at latest) are obtainable from the Secretary of the Institution, Aldine House, Bedford Street, W C 2

APPLICATIONS are invited by the trustees of the Dickinson scholarships in connexion with the Man chester Royal Infirmary and the University of Manchester for the following A research travelling scholarship in medicine value £300, and a pathology scholarship value £75 Particulars may be had from the Secretary to the trustees, Royal Infirmary, Manchester The completed forms must be returned by May 2

Calendar of Patent Records.

April 27, 1844.—The aneroid barometer was the invention of a Frenchman, Lucien Vidie, and was patented in England in the name of De Fontaine moreau, merchant, of London, on April 27, 1844. The advantages that it possessed over the mercury instrument, especially as regards portability, were apparent directly its accuracy for general purposes had been tested, and it was soon extensively adopted, especially in Great Britain.

April 27, 1909.—The modern metal spraying process for coating iron and steel is largely due to the Swiss chemical engineer, Dr. M. U. Schoop, whose first patent was applied for in Germany on April 27, 1909. The English patent was granted the following year.

April 28, 1784.—Stereotype printing was first introduced about 1726 by William Ged, but the earliest patent for the process was that granted to Alexander Tilloch and Andrew Foulis, printer to the University of Glasgow, on April 28, 1784. These and others of the early processes, though actually used for printing books, were only practised by the inventors themselves, and it was due to Lord Stanhope, who had been taught the art by Foulis, that the possibilities of the new method were generally realised. It was not, however, until the use of papier mâché for the matrix, in place of the plaster of paris formerly employed, was invented in France about 1828, that stereotyping was extensively adopted.

April 29, 1790.—On April 29, 1790, William Nicholson was granted a patent for the first rotary printing machine. Though the invention was not put into practice, it embodied suggestions which were successfully introduced by Koenig in his flat bed cylinder machine of 1811, and by Applegarth in his rotary press some years later.

April 30, 1844.—The 'Lancashire' steam boiler was the invention of Sir William Fairbairn and was patented by Fairbairn and John Hetherington on April 30, 1844. The boiler, which differs from its predecessor, the 'Cornish,' by having two tubular flues instead of one and by being internally fired, was the most economical one of its time, and by reason of its simplicity and its capacity of withstanding rough treatment, is still frequently preferred to other types for certain purposes.

May 1, 1704.—The use of jewelled pivot holes in watches was the invention of Nicholas Facio de Duillier, a Swiss resident in London, and a fellow of the Royal Society, and a patent for it was granted to him in conjunction with two London watchmakers, Peter and Jacob Debaufre, on May 1, 1704. A petition presented to the House of Commons for the prolongation of the patent was successfully opposed by the Clockmakers' Company, but it has since been discovered that the evidence which was the principal factor in securing the rejection of the petition was not genuine, and was probably 'faked' for the occasion.

May 2, 1782.—Among the claimants for the new prizes offered by the Board of Longitude for improvements in the marine chronometer after the award of the original £20,000 to John Harrison in 1764, were the rival London watchmakers, John Arnold and Thomas Earnshaw, who share the right to be called the inventor of the modern chronometer escapement, though the exact share of each in the invention has not been satisfactorily determined. It is precisely Earnshaw's escapement that is now in universal use, but Arnold's construction is very similar, gives few points to the other, and was the first, by a year, to be patented, the date of the grant being May 2, 1782. Arnold was the first to manufacture chronometers on a commercial scale.

Societies and Academies.

London

Physical Society, Mar. 8.—**Ezer Griffiths** and **J. H. Awbery**: The dependence of the mobility of ions in air on the relative humidity. The apparatus employed was a modification of Zeleny's original method, the end of a wind channel being closed by a disc of gauze fitted with a guard ring through which a steady stream of air of definite humidity was pumped. The motion of the negative ions due to the action of the air stream was balanced by a counter potential gradient, and the mobility deduced from the critical potential required to produce a balance. The rate of air flow was measured by means of an Ewing ball and tube flowmeter, using a hollow glass sphere to make it suitable for low air rates. Efforts were made to construct a direct indicating instrument.—**A. M. Tyndall**, with a note by **C. F. Powell**: Some unsolved problems relating to the mobilities of gaseous ions. The address dealt with: (1) Established results and proposed theories; (2) the difference between positive and negative mobilities; (3) the effect of vapours; (4) mobility in pure gases; (5) positive ions of short age; (6) suggestions as to future progress. Note by Mr. C. F. Powell: An apparatus of the 'four gauze' type has been designed for experiments with highly purified gases.

Linnean Society, April 4.—**G. M. Graham**: The natural history of the Victoria Nyanza. The Fishing Survey of Lake Victoria, 1927–1928, was carried out, by the author and Mr. E. B. Worthington, to solve a problem in economic fisheries. This involved a study of the general ecology of the lake. The cichlid fish, *Tilapia esculenta*, is the most important food species, and next in importance is *T. variabilis*. Excluding the shore, the lake may be divided into certain ecological zones—(1) the surface waters; (2) the deep mud region (190–230 feet); (3) the intermediate zone (50–150 feet); (4*a*) shallow water (less than 50 feet) where the ground is exposed; (4*b*) shallow water where there is shelter. These zones are distinguished by their fauna. The tropical situation of the lake results in (1) a constant plankton population; (2) rapid growth and decay, with perhaps more virulent parasitism; (3) more or less continuous reproductive activity.—**G. P. Bidder**: On the classification of sponges. In 1927 reasons were shown for regarding Hexactinellida, on account of their naked cells, as forming a phylum separate from the horny, calcareous, and four-ray sponges, with no common ancestors below Choanoflagellata. The needle sponges are now put in the latter phylum, and a complete classification is given.

Paris

Academy of Sciences, Mar. 18.—**P. Séjourné**: The line from Nice to Coni. Details of the construction of a new Alpine line, 63 kilometres long, more than one third of which is tunnel.—**Henri Villat**: A fundamental problem of the theory of vortices.—**Charles Achard** was elected a member of the Section of Medicine and Surgery in the place of the late Fernand Widal.—**Paul Pelseneer**: Academic biostatistics. A comparison of the age at election, average years membership, and age at death of members of learned societies at Paris, Brussels, London, and Washington.—**Dubourdieu**: The topological invariants of networks of curves and surfaces.—**Etienne Halphen**: A theorem on quadrics analogous with that of Chasles on conics.—**Hadamard**: Observation on the preceding note.—**Paul Mentré**: The principal surfaces of complexes of right lines.—**J. A. Lappo-Danilevski**: The

singularities of integrals of systems of linear differential equations with arbitrary rational coefficients —Radu Badescu Abel's integral equation generalised —R Gosse The determination of the equations $s = p\omega(x, y, z, q) + \theta(x, y, z, q)$, which admit an involution of order 2 and a second involution of higher order —Léon Pomey The integration of differential equations with general initial conditions (real variables) —Ernest Esclangon The apparent displacements of the pole star The Observatory of Strasbourg possesses a long series of observations of the pole star. An analysis of these data shows that the position of this star is not known with the precision desirable The possible causes of this systematic error are considered —Albert Arnulf, A C S Van Heel and Emile Perrin An optical method for the localisation of polished surfaces —Charles Guilbert A method of measuring very small electric currents, called tachymetric electrometry — R de Mallemann Magnetic rotatory power in an anisotropic medium — Decombe Pulsating electrified spherical pellicles, the principle of areas, and the Zeeman phenomenon —A Segay The inflammation of fire damp by explosives Discussion of the effect of adding common salt to the explosive and of placing a small cartridge containing liquid carbon dioxide alongside the explosive —H Caron and L Vanbockstael A new isomorphous series of fluorine compounds Mixtures of hydrofluosilicic acid, calcium chloride, and aluminium sulphate give octahedral crystals, the composition of which was found to be $4CaSiF_6$, $8CaF_2$, $Al_2(SO_4)_3$, $45H_2O$ These are very slightly soluble in water and may be utilised in microchemical analysis as a test for calcium, aluminium, and sulphur —L Neltner The extension of the Cambrian in south Morocco and the presence in this region of pre Cambrian folds —J Thoulet The Kurosio current of Japan —L Eblé and J Itié The values of the magnetic elements at the station of Val Joyeux (Seine et Oise) on Jan 1, 1929 —Joseph Richard The antherozoids of *Fucus* —Theodureto de Camargo, R Bolliger, and Paulo Correa de Mello The influence of the hydrogen ion concentration of the culture medium on the development of the coffee tree, *Coffea arabica* The coffee plant develops best in acid media, the optimum acidity being between pH 4 2 and pH 5 1 The plant is very sensitive to the action of lime, a very small amount of which is distinctly harmful — W Russell and L Hedin New cisalpine African Leguminoseæ with secretory apparatus —Abeloos The influence of temperature on the growth of the *Planaria* The maximum size is, for given conditions of nutrition, a function of the temperature and decreases notably when the temperature is raised The speed of growth is a maximum at 12° C, smaller at 20° C, and still smaller at 8° C —Pierre P Grassé and Mlle Odette Tuzet The origin and nature of the supposed cephalic skeleton of sperm —G Delamare and C Gatti Spirochætes and treponemes from a venerian granulome

ROME

Royal National Academy of the Lincei, Jan 6 — F Severi and B Segre A topological paradox — G Giorgi The propagation of waves in media with selective absorption By means of an example it is shown how physical phenomena which should depend on matrices of infinite order may be brought back to finite matrices combined with normal functional operators —U Cisotti Certain space integrals in the complex plane —G Fano An example of birational cubic transformation inherent to a linear complex — G Fubini A problem of the theory of the congruences of straight lines, with applications to the problem of the spherical representation of a non Euclidean surface and to a theorem of Bianchi and Blaschke —G A Crocco Considerations on the guiding of an aeroplane in cloud —G Armellini The astronomical refraction at Rome The results of a preliminary measurement indicate that at Rome the refraction constant C has a value slightly greater than 60 154″, and also that this varies somewhat with the season of the year, in virtue of its connexion with other modern astronomical questions, this phenomenon deserves further investigation Application of the method of least squares to the data as yet obtained yields for C the value 60 51″, which lies between the number 60 15″ now adopted by the "Connaissance des Temps" of Paris and that now found at Abbadia, namely, 60 61″, and is, moreover, very nearly in agreement with the old value, 60 44″, given by Radau in the *Annales* of the Paris Observatory —S Franchi The distant re-outcrop at a great height of the inverted nummulitic syncline of Valdieri —E Bompiani Various determinations of the projective normals of a surface — G Vitali Hamilton's principle It is shown that this principle of classical mechanics may be written in a form which satisfies the following two conditions (1) It should render evident the necessary invariance of the integral of which the variation is to be annulled by an invertible substitution on the integration variable, and (2) the system of Euler's equations into which the annulling of the variation of the integral is translated is changed into an equivalent when the integral is subjected to an invertible substitution on the system of four co ordinates constituted initially of three Cartesian co ordinates and of time Further, a proof is given of the known fact that, for slow motions, Hamilton's principle is translatable with sufficient approximation into the system of equations of the geodetics of a space, the linear element of which is expressed by the elements figuring in the ordinary problem and by a constant c sufficiently great —M Previatti Bortolozzi The equivalence of two equations presented in the determination of Vitali's principal terna for a generic surface of Hilbertian space — J Kanitani An intrinsic quadratic form in relation to the hypersurface in projective space of several dimensions —P Barreca Deduction of the experimental law of the duration of twilight colours of the clouds, and the probable discrimination between the theory of a macroscopic diffractive screen (terraqueous globe) and that of microscopic screens (dust) The author has previously shown deductively that the mean durations of the twilight colorations of the clouds are proportional to their respective wave lengths and also to a number relating to the order of the annular spectrum surrounding the globe A proof is now given of the theorem that, if in an isotropic medium there are two punctiform sources of monochromatic light, vibrating persistently from infinite time, and if, further, there are opaque screens of any form but similar geometrically in relation to the respective wave lengths and situated similarly with respect to the sources, these produce diffraction fringes which are geometrically similar and situated similarly —A Belluigi The form of deep, gravimetrically perturbing masses —M Lombardini The viscosity of the air and the constant of surface friction at the experimental station of Vigna di Valle —M Amadori Condensation products of p phenetidine and glucose (2) Investigation of the two condensation products previously obtained shows that the condensation of a primary aromatic amine with glucose gives rise to (1) a compound of glucosidic character formed by the reaction of one hydrogen atom of the amino group with the hydroxyl of the glucose, and (2) a basic compound, resulting from the interaction of two

hydrogen atoms of the amino group with the ketonic oxygen of the aldehydic group or of the lactonic linking of the glucose.—R Altschul New method of impregnation with gold In the impregnation of tissues with gold, the use of mercuric bromide together with gold chloride yields results quite different from those hitherto observed —T Carpanese The pro chlorite of Monte Rosso di Verra (Monte Rosa group) The dehydration of this specimen of prochlorite—which contains little iron—when heated follows a course perfectly analogous to that observed with pennine from Zermatt and with clinochlore from Val Devero The existence of a hydrate containing about 5 per cent of water and stable at 550° 700° C is indicated Re-absorption of moisture from the air proceeds rapidly at first and then gradually slackens and ceases The mineral undergoes optical trans formation when heated, the optic axial angle being annulled and the sign changing to negative, after wards biaxial character is assumed, the mineral re maining negative but with the plane of the optic axes perpendicular to the original position —P Principi Outcrops of 'scaly clay' in Northern Umbria —L De Caro The isoelectric point of myoprotein and the regulating power of muscular juice The regu lating power of the muscle juice of *Emys*, *Scyllium*, and of the electric organ of the torpedo, measured by the ratio $\Delta B/\Delta p\mathrm{H}$, exhibits two minimum values at about $p\mathrm{H} = 7\ 7$ and 5 7 From the former value it increases rapidly on the alkaline side and from the latter on the acid side —B Monterosso Cirrepedo logical studies (5) Anabiosis and revivescence in *Chthamalus* —L Mamoli The adenoid tissue in the normal human lachrymal gland The characters of this tissue, as observed in fifteen living and sixteen dead individuals, varying from a six months old fœtus to an octogenarian, are described —P Pasquini Phenomena of regulation and reparation in the development of the eye of amphibia (results of new experiments on the removal and transplantation of the optical vesicle in *Pleurodeles*, *Axolotl*, and *Rana*) The processes of compensatory regulation during the development of the optical vesicle in these organisms show, in their quality and degree, that this vesicle must be regarded as a specific equipotential and auto differentiable system —L Sanzo Egg and larva of the tunny (*Orcynus thynnus* Ltkn) —B Strampelli Significance of the Heinz Ehrlich bodies, and their relations between macrophagic and myeloplaxic apparatus

Royal Society of Medicine (Surgery and Medicine Sections), at 8 30 —A. J Walton (Surgery), Dr H Thursfield (Medicine) and others Discussion on The Indications for and the Results of Splenectomy

THURSDAY, May 2

Iron and Steel Institute (Annual Meeting) (at Institution of Civil Engineers), at 10 A M —Presentation of Bessemer Gold Medal to The Hon Sir Charles Parsons.—Prof H Louis Presidential Address —Papers for discussion —First Report on Blast Furnace Plant and Practice by a Committee of the Institute.—E H Lewis Twenty Months Results of Dry Blast Operation —W E Simons The A.I B Sinter Plant at Messrs Guest, Keen and Nettlefolds Ltd Cardiff Works.—At 2 30 —R. H Greaves H H Abram and S. H Rees The Erosion of Guns —H Sutton The Influence of Pickling Operations on the Properties of Steel —G A Hankins and Miss G W Ford The Mechanical and Metallurgical Properties of Spring Steels as Revealed by Laboratory Tests.

Royal Society at 4.—Election of Fellows —At 4 30 —Dr J S Haldane, W Hancock and A. G R Whitehouse The Loss of Water and Salts through the Skin and the corresponding Physiological Adjustments —Dr F H A. Marshall and J Hammond Œstrus and Pseudo-Pregnancy in the Ferret.—R. G Canti and F G Spear The Effect of Gamma Irradiation on Cell Division in Tissue Culture *in vitro* —R. B Bourdillon, C Fischmann, R G C Jenkins, and T A. Webster The Absorption Spectrum of Vitamin D —*Papers to be read in title only* —G E Briggs Experimental Researches on Vegetable Assimilation and Respiration XX —R J Lythgoe and K. Tansley The Relation of the Critical Frequency of Flicker to the Adaptation of the Eye.—R Hill Reduced Hæmatin and Hæmochromogen

Linnean Society of London at 5.—H H Haines Some Aspects of the New Forest, with Special Reference to the Changes Wrought by Direct or Indirect Human Agency —F S Russell A General Account of the Great Barrier Reef Expedition and its Aims.—G Tandy A Preliminary Account of the Vegetation of Low Isles (The Great Barrier Reef Expedition).—H W Pugsley A Revision of the British Euphrasias (*By title only*)

Institute of Pathology and Research (St. Mary s Hospital, W 2), at 5 —Prof C A. Ariens Kappers The Phylogenetic Development of the Protopathic and Epicritic Centres in the Central Nervous System.

Royal College of Physicians of London, at 5.—Dr F M R Walshe The Physiological Analysis of some Clinically Observed Disorders of Movement (Oliver-Sharpey Lectures) (II).

Chemical Society, at 8.—Prof I M Heilbron, W M Owens, and I A Simpson The Unsaponifiable Matter from the Oils of Elasmobranch Fish Part V The Constitution of Squalene as deduced from its Degradation Products —Prof I M Heilbron and A Thompson The Unsaponifiable Matter from the Oils of Elasmobranch Fish Part VI The Constitution of Squalene as deduced from a Study of the Decahydrosqualenes —Prof I M Heilbron and W A. Sexton Studies in the Sterol Group. Part III The Acetylation and Catalytic Hydrogenation of Ergosterol —Prof I M Heilbron, W A Sexton, and F S. Spring Studies in the Sterol Group Part IV The Existence of Isomeric naturally occurring Ergosterols.—Prof. I M Heilbron and F Irving Styrypyrylium Salts Part XI The Determination of the Reactive Group in Ketones of the Type CH_3 CO CH_2R by means of the Benzo β naphthaspiropyran Colour Change.—G A. R. Kon and R P Linstead Catalytic Influences in Three Carbon Tautomerism Part I Sodium Alkyloxides

Royal Society of Medicine (Tropical Diseases Section), at 8 15 —Annual General Meeting

FRIDAY, May 3

Iron and Steel Institute (Annual Meeting) (at Institution of Civil Engineers), at 10 A M —Announcement of the award of the Andrew Carnegie Research Scholarships for 1929 30.—Presentation of the Carnegie Gold Medal to Dr A Bramley —The Hon Sir Charles Parsons and H M Duncan A New Method for the Production of Sound Steel —Third Report on Heterogeneity of Steel Ingots, by a Committee of the Institute —J M Robertson The Microstructure of Rapidly Cooled Steel —D Lewis The Transformation of Austenite into Martensite in a 0·8 per cent Carbon Steel —A. L Norbury Constitutional Diagrams for Cast Irons and Quenched Steels.—At 2 30 —G R. Bolsover Brittleness in Mild Steel —L. B Pfeil The Oxidation of Iron and Steel at High Temperatures —E G Herbert and P Whitaker The Differential Method for Measuring the Thickness of Hard Cases without Sectioning them —T E. Rooney and G Barr A Method for the Estimation of Hydrogen in Steel

Royal Society of Medicine (Otology Section) (Annual General Meeting), at 10 30 A.M —T Neville Treatment of Chronic Deafness by Diathermy and Ionisation

Royal Astronomical Society (Geophysical Discussion), at 4 30 —Cloud Formation C J P Cave Sir Gilbert Walker Chairman, Sir Frank Dyson

Royal Society of Medicine (Laryngology Section) (Annual General Meeting), at 5 —F J Cleminson Treatment of Carcinoma of the Œsophagus by Radium

Philological Society (at University College), at 5 30 —Anniversary Meeting

Institution of Electrical Engineers (Meter and Instrument Section) at 7 —G D Malcolm Chairman s Address

Institution of Mechanical Engineers (Informal Meeting), at 7 —H Berry London s Water

Geologists Association (at University College), at 7 30.—Dr S. W Wooldridge and A. J Bull The Arun Gap and Lower Greensand around Pulborough

Institution of Automobile Engineers (jointly with Institution of Production Engineers) (at Royal Society of Arts), at 7 45 —H F L Orcutt The Production and Application of Ground Gears (Lecture)

Royal Society of Medicine (Anæsthetics Section) (Annual General Meeting), at 8.30 —Dr H Sington Pre medication by Paraldehyde in Children

Royal Institution of Great Britain at 9 —Sir Daniel Hall The Garden Tulip.

PUBLIC LECTURES

FRIDAY April 26.

World Association for Adult Education (16 Russell Square, W C 1), at 8.30.—Miss R M Fleming Soil and Civilisation in Russia.

MONDAY, April 29.

Bedford College for Women at 5.15 —Dr V Stefansson Abolishing the Arctic

University College, at 5 15.—Prof E Mellanby Drug like Actions of some Food Constituents. (Succeeding Lectures on April 30 and May 1)—At 5 30 —Prof H F Baker Geometry a Brief Review (Succeeding Lectures on May 7 and 13.)

WEDNESDAY May 1

Bedford College for Women, at 5 15.—Dr V Stefansson The Northward Course of Empire

THURSDAY, May 2

St Thomas s Hospital, at 5.—Prof S J Cowell Dietetics (Succeeding Lectures on May 9, 16, 23, 30, and June 6.)

University College, at 5 —R. J Lythgoe Special Sense Physiology (Succeeding Lectures on May 9, 16, 23, 30, and June 6)

FRIDAY, May 3

University College, at 4.—Prof A. J Hall Some of the Sequela of Epidemic Encephalitis (Lethargica) —At 5 30 (Succeeding Lecture on May 10)—Prof R. Robinson Public Inaugural Lecture

Imperial College of Science and Technology, at 5.30.—Prof F O. Bower The Origin of a Land Flora reviewed 21 Years after Publication (Huxley Memorial Lecture).

SATURDAY, MAY 4, 1929

The New University of London

THE title of this article is not intended to imply any disrespect for the 'old' University of London in any of its previous incarnations In accordance with the new statutes under the University of London Act of 1926, sealed by the Privy Council on Mar 21, the University is going through a process to which the now familiar word 'rejuvenescence' would perhaps be more appropriate than 're birth', for the University, established in 1836, is not old as such institutions go, and shows few of the stigmata of senility But all institutions of the kind live a rhythmical life, and require periodic adjustment to changing conditions This is the third time that the University of London has received special attention from the Government of the day, and we may question whether the proverbial attribute of the 'third time' will be confirmed in this case

The original charter incorporated persons of eminence in arts and science for the purpose of awarding degrees to students of University College and King's College and other colleges which might become affiliated In 1858, a new charter created Convocation and granted to the graduates important privileges in relation to the government of the University At the same time, the system of affiliating colleges was virtually abandoned, being replaced by the policy of the 'open door' In 1900, after a spate of argument, new statutes, based on the Act of 1898, erected the loosely jointed framework of a teaching University, and now, after another spate of argument, the attempt has been made to quicken the life of the University, without altering its essential character

What is the essential character of the University of London? Like its medieval prototypes, it is a self governing guild of teachers, graduates, and students Let us not forget that the medieval university was a research as well as a teaching institution The fellowship system originated in a desire to promote study, and not to promote teaching, indeed, the founder of Queen's College, Oxford, expressly declared that he intended his benefaction to relieve his fellows from the necessity of teaching At Oxford and Cambridge the collegiate system was a later development, an afterthought, due to domestic rather than to educational considerations, and those universities have outgrown the misconception of a university as a federation of colleges, a misconception which impeded their progress for some centuries The present is surely an inopportune moment to force

forward, as some influential members of that University are doing, an alien conception of the University as a "federation of autonomous institutions" It is true that, under the new statutes, the link between the University and its colleges has been strengthened, but the University exists apart from its colleges, and must be free to live its own life, to do its peculiar work for the extension of higher education and research, whether directly or through existing agencies or through new agencies This obligation is emphasised rather than weakened by the new arrangements to be made by the Government and by the London County Council for the allocation by the University of public grants for university education within the London area If the University is to be merely a clearing house for autonomous colleges, it can never hope to gain the public esteem to which the university of the metropolis of the Empire should be entitled

Readers of NATURE are specially interested in the promotion of scientific research, and an application of our thesis is ready to hand One of the current controversies in the University relates to the promotion of scientific research Should it be concentrated in the colleges in close touch with undergraduate teaching or stimulated and developed by the creation of a series of research institutes, as at Cambridge? The best way to deal with a dilemma is often to adopt both alternatives For our part, while recognising that every encouragement must be given to the prosecution of scientific research in the colleges, we are not satisfied that the University will make its due contribution to scientific discovery if it restricts its research work in this way

That we are not discussing the question *in vacuo* is indicated by a report of the Site and Buildings Committee received by the Senate of the University on Jan 23 on the utilisation of the Bloomsbury site of about eleven acres It is proposed to allocate a large part of the area to residential purposes, but the Committee "do not at present propose that the University should build laboratories" There is no evidence that the professors wish to live next door to one another on one of the most valuable sites in the world It is not a London characteristic But if the reference in the sentence quoted from the Committee's report is to laboratories for scientific research, we would urge the new Senate to announce at the earliest moment an intention on the part of the University to build on the Bloomsbury site a great Temple of Science, to use Lord Rosebery's phrase, dedicated to the silent pursuit of scientific truth, a noble counterpart of St Paul's Cathedral As Mr H G Wells has well said, the University of London has "to supply facilities for research upon an altogether unprecedented scale, it has to maintain itself as the intellectual centre of the entire Empire"

The question of the promotion of scientific research will be one of the most important facing the new Senate, now in process of election, and of the subordinate Faculty of Science and Boards of Students Electors, whether teachers or graduates of the University—each category is to contribute seventeen members to the Senate, making together two thirds of the membership—should recognise their serious responsibility in this matter Men and women are required capable of rising above the jealousies and intrigues which have hindered the progress of the University in the past, capable of taking a synoptic view of the needs and problems of university education in London, of pressing steadily forward to a clearly defined conception of the university which London ought to possess

There are many questions relating to the organisation of the new University of London which might be usefully discussed, such as the question of the University area, the work of the University in extending higher education—it is difficult to understand why the vast area of London "across the bridges" is almost *terra incognita* as regards university education—the popularisation of knowledge, the cultivation of art, music, and the drama, the founding of a great school of law, the creation of a great international centre for the exchange of thought and practice, the provision of a great meeting place for conferences of all kinds bearing on education, science, economics, government, national and Imperial development We prefer, however, to stress the importance of the elections to the Senate as the dominating issue at the moment

For the first time in its history the University of London, thanks to the Rockefeller Foundation and to the Government, has its own land on which it can build its buildings and discharge its purposes, not the least important of which is, to quote from the new statutes, "to promote research and the advancement of science and learning" May Henry VIII's wise words, addressed to the University of Oxford, prove true in the case of the University of London "I tell you, sirs, that I judge no land in England better bestowed than that which is given to our Universities, for by their maintenance our Realm shall be well governed when we are dead and rotten"

Travellers' Tales

(1) *The Book of the Marvels of India* By Buzurg Ibn Shahriyar From the Arabic by L Marcel Devic Translated into English by Peter Quennell (The Golden Dragon Library) Pp vi + 164 (London George Routledge and Sons, Ltd, 1928) 6s net

(2) The Broadway Travellers' Series *Hans Staden the True History of his Captivity, 1557* Translated and edited by Malcolm Letts with an Introduction and Notes Pp xx + 191 10s 6d net *Thomas Gage, the English American a New Survey of the West Indies, 1648* Edited with an Introduction by Dr A P Newton Pp xxxii + 407 + 12 plates 15s net *Travels in Persia, 1627–1629* By Thomas Herbert Abridged and edited by Sir William Foster, with an Introduction and Notes Pp xl + 352 + 13 plates 15s net (London George Routledge and Sons, Ltd, 1928)

(3) *Adventures of an African Slaver being a True Account of the Life of Captain Theodore Canot, Trader in Gold, Ivory, and Slaves on the Coast of Guinea, his Own Story as told in the Year 1854 to Brantz Mayer, and now edited with an Introduction by Malcolm Cowley* Pp xxii + 376 + 9 plates (London George Routledge and Sons, Ltd, 1928) 15s net

WHY is it that nine out of ten modern books of travel are intensely dull and yet early travels never seem to fail in their appeal to the imagination or their hold on the attention of the reader? This is equally true whether they break what, in their author's time, was new ground, or follow a beaten track In all these books under notice there is scarcely a dull page

(1) 'The Book of the Marvels of India" calls for no extended comment, though it is infinitely entertaining It is a collection of stories current among Arab seafarers in medieval times, full of marvels described with a wealth of detail and here and there a sly touch of humour It was obviously on some common stock that the authors of Sindbad in the "Arabian Nights," of Sir John Mandeville, the author of this collection, and other writers of similar tastes, drew for their accounts of the wonders of the East The roc, the old man of the sea, the island of women, and other familiar marvels, will be found here, but in such a form as not entirely to preclude a remote foundation in reality

(2) This, with the two volumes mentioned next in order, is issued in the excellent series of Broadway Travellers, for which we are indebted to the scholarship of Sir E Denison Ross In this series the travels selected for publication have been chosen with much discrimination, while in illustration, type, and form, the series as a whole is very pleasing

Hans Staden's account of his captivity among the Indians of Brazil is a remarkable document A Dutchman of the middle sixteenth century who served the Portuguese as a gunner he visited Brazil twice, being captured on the second occasion The Indians, whom he usually but not invariably calls Tupinambu, made a practice of eating their prisoners if they were Portuguese Staden barely escaped that fate He gives a unique account of the details of their method of procedure

Thomas Gage, the author of the 'English American,' was a man of very different type Educated as a Jesuit in France and Spain, he became a Dominican and went to America, where he stayed for twelve years as a missionary His book written on his return to England, was the first authentic account of Spanish America and the West Indies to be written in English It had a great vogue in the seventeenth century, dropped into oblivion, and had not since been reprinted This was no doubt due to the fact that, the author having changed his religion, his theological polemic as well as his narrative were used by the Commonwealth as propaganda against Spain and caused the very real merits of part of his work to be forgotten The editor has judiciously excised those parts of his book which make no appeal to the modern reader

Gage was scarcely an admirable character—he acted as informer against his former co religionists—and it is characteristic of the man that he expects much of what he has to say not to be believed

Herbert, author of 'Travels in Persia," accompanied Sir Dodmore Cotton on the embassy to Shah Abbas in 1627, and was thus the precursor of Tavernier, de Chardin, and other great travellers of the seventeenth century He returned to England in 1629, and published his book in 1633 He afterwards issued several enlarged editions The book is of considerable historical importance, as it is the only detailed account of the first English embassy to Persia Herbert had a good opportunity of seeing something of the country, as not only was the embassy compelled to make a stay of some length, but also, owing to the absence of the Shah from his capital on their arrival, they had to follow him so far as Kasvin Herbert was an acute, if not very profound, observer, and gives a very good account of the Persia of that day His

observations of the peoples seen at the ports at which they touched on the voyage around the Cape are also of considerable interest

(3) "Adventures of an African Slaver" is noteworthy as a graphic account of conditions in the slave trade in the earliest part of the nineteenth century when it had been prohibited, transcribed from the oral narrative of the protagonist by an American journalist It is absorbing, if rather horrifying, as a story and valuable as a historical document

The Movements of Plants

The Motor Mechanism of Plants By Sir Jagadis Chunder Bose Pp xxv + 429 (London, New York and Toronto Longmans, Green and Co, Ltd, 1928) 21s net

IT is safe to assume that there are certain fundamental resemblances in the behaviour of all living cells in virtue of their possessing the same ground plan of protoplasmic structure, and among all aerobic cells in virtue of a similar oxidative mechanism, as the recent work of Keilin suggests Among all animal contractile cells, again, there are general resemblances When, therefore, we consider the observations of Sir Jagadis Bose on plant movements from the point of view of general physiology, we have to decide whether the resemblances he finds are merely common properties of living protoplasm as such, or of excitable protoplasm, or contractile protoplasm, and whether there are specific differences between the processes of animal and plant

In the present work, as in all the work of Sir Jagadis Bose, the apparatus and methods used combine delicacy and simplicity in a delightful way For example, nothing could be neater than the various types of tapping recorder described on pp 16 28, for writing without friction on a smoked surface and in the same process making a time record Another ingenious device is the 'quadrant' method for recording the change in electrical resistance of a leaf on exposure to light (p 194) A circular leaf is connected up to a battery and galvanometer by four leads so that the leaf is divided into quadrants, each of which forms one arm of a Wheatstone's bridge By adjusting the position of one contact the bridge resistances are balanced Two opposite quadrants can be exposed to light while the others are kept in the dark by a screen cut to the correct shape If the illuminated quadrants vary in resistance, the galvanometer deflection will be proportional to the product of the changes, so that a method of high sensitivity is obtained with a minimum of apparatus

The use of this device illustrates the chief defect in this work, the lack of experimental controls The galvanometer deflections are taken at their face value as measuring change of resistance without any inquiry as to whether the 'action current' of the excited tissue may not be a complicating factor So far as the description goes, this method, and another one mentioned, may be simply rather roundabout ways of recording the action current The great similarity of the curves in 'resistance' and of electrical change lends colour to this suspicion

Some other points in the book where similar criticism is called for may as well be dealt with at once Be it understood that criticism is directed solely against the case as presented in the volume under notice, Sir Jagadis must not blame the reader for ignoring other evidence which is not quoted The first case is the use made of the very ingenious magnetic method for magnifying the movement of a lever By this method a movement can be magnified ten million times (p 346) At this magnification temperature control to 0 01° C would seem to be called for, but no indication is given that a thermostat was used at all Using this instrument, an oscillatory response was obtained in stems in which there was an active flow of sap The oscillations might have been due to the natural period of the instrument They were probably not, but no evidence is given on the matter Again, if the oscillations are genuine their period should correspond with that of the electrical changes described previously, and changes in amplitude should be in the same direction in both cases, but no information of this sort is given, so that the results must be accepted with reserve

In Chapter ix experiments are described on excitation with constant current Owing to the slow conduction of excitation, it is easy to see from which electrode the excitation process starts in any plant that makes an obvious movement With currents near the threshold potential, excitation occurs at the cathode at the make of the current only, with rather stronger currents up to about twice the threshold value, excitation occurs also at the anode at the break This is strictly according to the behaviour of animal tissues With stronger currents, however, there is excitation also at the anode at the make, with stronger still at the cathode at the break If these results were taken at their face value, as the author intends them to be, they would imply the existence of a new type of excitation process, but the data do not warrant such an extreme

conclusion When a current is passed through a tissue with cells arranged in series as well as in parallel, each cell in the region of the flow has a cathodal and anodal region With weak currents a few cells only near each external electrode will be subjected to a potential approaching the threshold value, and the probability is that cells near the external cathode will experience the highest potential at their cathodal end and those near the anode at their anodal end, and will be excited accordingly With potentials above that required to excite at the external anode at the break, some of the cells near the external anode may have local cathodes at which excitation occurs, and correspondingly near the external cathode There is no reason to doubt the observations, but good reason to doubt the naïve conclusions drawn from them

In several of the experiments described in Chapters xiii and xiv, which deal with the electric response on stimulation, positive galvanometer deflections were found as well as negative These positive deflections are interpreted as genuine action currents in the opposite direction to the usual action current In every case, apparently, both electrodes were placed on functional tissue, but as one was in contact with a more obviously active region, it is assumed that all galvanometer deflections were due to changes in that region, and that no changes occurred elsewhere that could affect the other electrode This seems a rash assumption, and it is a pity it was apparently not tested, as it easily could have been by placing the second electrode on killed tissue It is true that several observers have claimed to find positive electrical changes in the heart when it is inhibited by stimulation of the vagus nerve, but the interpretation of the results is not clear and the case is a special one

Turning now to the more grateful task of summarising the chief positive results there is clearly a fundamental similarity between the processes of excitation and conduction in plant and animal, but certain interesting differences The actual contractile process in the plant seems to be different Two main types of movement have been investigated The first is leaf movements, such as those of *Mimosa pudica*, which are compared with the response of skeletal muscle, and the rhythmical movements of *Desmodium gyrans*, which suggest those of heart muscle The other type is the process of sap propulsion in the stem As the same tissue is concerned in leaf movement and sap propulsion, it would seem natural to look for a connexion between the two processes, this possibility the author does not, however, discuss

The leaf movements of *Mimosa* can be studied either in the intact plant or in isolated preparations The tissue is very sensitive to electrical stimulation by single induction shocks Torsion of the stem and other mechanical stimuli are effective, as can be shown by the electrical response Light can act as a stimulus to *Mimosa*, and the plant is more excitable when illuminated, so much so that a cloud passing across the sun will cause a diminished response to electrical stimulation Subliminal stimuli become effective on repetition The contraction occupies about one second after a latent period of one tenth of a second Relaxation takes several minutes The tissue is refractory after stimulation It is readily fatigued and shows a ' staircase ' effect with a few successive stimuli

The character of the phenomena, particularly the slow response, together with sensitivity to electric currents of short duration, does not suggest the behaviour of an isolated muscle or muscle nerve preparation, but something more like a reflex, where the sensitivity and speed of reaction of the receptor mechanism need not resemble that of the effector mechanism Comparison with reflex processes in vertebrates cannot be ruled out, but a closer analogy is probably to be found in such a reflex, if it can be so called, as the retraction of the syphons of the clam (*Mya arenaria*) on exposure to light or other stimuli (cf Hecht, *Jour Gen Physiol*, vols 1 and 2)

The movement in question consists of contraction of certain cortical cells of the leaf joint There is a large body of active cells on the lower side the contraction of which generally masks the feebler action of the cells on the upper side, consequently, the normal movement on stimulation is a fall of the leaf, but under suitable conditions an active erection can be demonstrated The contraction, unlike the animal contractile process, consists of a diminution of volume, whereby sap is squeezed out of the cells This accounts for the slowness of the relaxation, which is governed by the uptake of sap With excessive turgor the movement is diminished or even abolished, though the electric response remains (p 168) In the dark the leaf preparation or plant becomes excessively turgid—' subtonic,' the author calls the condition In this state the first stimulus applied elicits only a small erectile response, with successive stimuli the opposite and normal response gradually reasserts itself The phenomena appear to be sufficiently accounted for if we consider that turgor merely masks the response of the cells, makes them contract isometrically, and affects the cells of the lower side more than those of the upper,

as is indicated by a greater erection than usual With repeated stimulation the turgor is gradually worked off

Sir Jagadis, however, considers (pp 48 56 and 233 237) that the energy of the stimulus has not merely a trigger action but may also contribute to the available potential energy of the tissue, that the 'subtonic' condition is one of lowered potential energy, and that an erectile response involves an increase of potential energy (what if the plant be turned upside down?) Let it suffice to say that the theory, if the reviewer has not misunderstood it, would imply that the mechanism of plant movement is utterly unlike anything found in the animal kingdom

Experiments are described showing that the effect of many drugs on muscle and on plant response are similar, but the work is of less importance than it might have been had the drugs been more judiciously selected It is not specially interesting to be told that general protoplasmic poisons such as ether or sulphuretted hydrogen depress activity, because one could have predicted as much With such nonspecific agents, quantitative comparison of the susceptibility of different cells would be of interest, but not a merely qualitative comparison Of much greater interest are the few experiments quoted on the action of specific drugs, such as those showing a similar action of muscarine, pilocarpine, and atropine on frog's heart and the movements of *Desmodium* (p 269)

As the contractile process is essentially a reduction in volume of the active cells, the diameter of a leaf stalk or a stem will be slightly diminished on stimulation This change has been measured by means of a high magnification lever system (Chapters xi and xii) In the leaf stalk of *Mimosa* all the cortical cells appear to be active, consequently the contraction of a single cell can be calculated With maximal stimulation the change in diameter of the cell is 13 per cent, which implies a volume change of about 35 per cent if contraction is uniform in all directions The method of measuring the change in diameter on stimulation enables the activity of many plants which make no obvious movements to be investigated A contractile process can be demonstrated in many common plants, such as the bean and *Impatiens* The recorded movements are small and slow, and the latent period is long, but the difference between 'active' and 'inactive' plants is clearly a matter of degree The inactive plant contains fewer or less developed contractile cells, but some active cells have been shown to be present in many herbaceous plants and shrubs This is not surprising if we accept the author's further contention that sap propulsion is due to a contractile mechanism in the cortex If the excitation process spreads along a stem, the effect of successive contraction of cortical cells is bound to be a forward movement of sap, if a considerable number of cells in one region can be excited simultaneously and they are predominantly on one side of the structure, the effect will be a movement of the structure as a whole

Sir Jagadis Bose argues convincingly against the view that the ascent of sap is due solely to the action of the roots and leaves, while the rest of the plant is passive and is only a system of tubes By several different experimental methods he shows that there is a flow of sap in isolated stems and an active process in the cortex (Chapters xxii xxix) It is possible to object to his use of the term 'peristalsis' for the sap pumping process, as the analogy has not been demonstrated except in a vague way, but the objection is of no great moment Propulsion of sap is found to be a normal response to stimulation The direction of flow is always from an excited region to an unexcited region, but the pressure produced by propagation of the excited state in the normal direction is about four times as great as that produced in the opposite direction The active tissue is identified as cortical by exploring with a needle electrode until the place of maximum electric response is found

Something ought to be said of the performance of *Desmodium gyrans*, the telegraph plant (Chapter xix) Under normal stimulation by light, the leaflets keep up a rhythmic movement with a period of two minutes or so In the dark these 'spontaneous' movements cease after a time, but the plant can be excited electrically or by a light With a weak stimulus it will give a single response, with stronger stimulation a series Apparently other plants will give several responses with moderately strong stimuli, but *Desmodium* is more excitable, less readily fatigued, and shows this phenomenon of 'after discharge' in a far more striking manner It is remarkable to find still another character of the motor response of plants suggestive of reflex movement in animals

For the investigation of processes of excitation and conduction, and of some peculiar types of contractile process, the vegetable kingdom evidently offers very great scope All those interested in these aspects of general physiology will be grateful to Sir Jagadis Bose for his pioneer work, and for the extraordinarily ingenious methods he has devised A D Ritchie

Kinetic Theory and Electric Conduction through Gases

Conduction of Electricity through Gases By Sir J J Thomson and Prof G P Thomson Third edition Vol I *General Properties of Ions, Ionization by Heat and Light* Pp vi+491 (Cambridge At the University Press, 1928) 25s net

THE Geissler tubes and Crookes tubes that were in almost every physical laboratory at the end of the last century enabled any student to observe with ease the fascinating phenomena of electric discharges in gases at low pressures These and the newly familiar phenomena of radioactivity and X rays made the theory of electric conduction through gases appear to be of bewildering complexity

One of the most remarkable chapters in scientific history is that of the development of our knowledge of these phenomena Perhaps the greatest single factor responsible for the rapidity of the progress was the publication in 1903 and 1906 of the first and second editions of Sir J J Thomson's book The world wide interest thus aroused by these discoveries, which had originated so largely in the Cavendish Laboratory, has had a profound effect on almost every branch of modern physics

The great influence of the book was due not so much to the importance of the discoveries which it described, as to the fact that it was in itself a new scientific contribution The results of previously published investigations were discussed in a most critical, but constructive, manner, frequently new points of view were developed and new or improved methods of experimental investigation were suggested For example, on p 222 of the second edition in proposing a method for determining e/m, differential equations were derived which were applicable to the potential distribution in a pure electron discharge in high vacuum When in 1912 the experimental conditions for obtaining pure electron discharges limited by space charge were found, it was only necessary to perform one more integration of Thomson's equation and introduce the boundary condition $dv/dx=0$ at the cathode to derive an equation for the relation between current and voltage in devices having discharges of this character

The spirit in which the book was written is best illustrated by the first and third paragraphs of the preface to the first edition

" I have endeavoured in this work to develop the view that the conduction of electricity through gases is due to the presence in the gas of small particles charged with electricity, called ions, which under the influence of electric forces move from one part of the gas to another My object has been to show how the various phenomena exhibited when electricity passes through gases can be co ordinated by this conception rather than to attempt to give a complete account of the very numerous investigations which have been made on the electrical properties of gases I have, therefore, confined myself for the most part to those phenomena which furnish results sufficiently precise to serve as a test of the truth of this theory

'With the discovery and study of Cathode rays, Rontgen rays, and Radio activity, a new era has begun in physics, in which the electrical properties of gases have played and will play a most important part the bearing of these discoveries on the problems of the Constitution of Matter and the Nature of Electricity is in most intimate connection with the view we take of the processes which go on when electricity passes through a gas '

The methods of analysis which were used in the book are essentially a development of the classical methods that Maxwell employed in his development of the kinetic theory

In the twenty two years that have elapsed since the publication of the second edition, our knowledge in this field has been increasing at an ever accelerating pace Furthermore, industrial applications of the utmost importance, especially in telephony and radio communication, have been built upon the foundations laid by Thomson New and even more important applications are almost within sight

The advent of the third edition of this book must thus arouse extreme interest It is not surprising that there are now to be two volumes The preface by Sir J J Thomson says 'The preparation of this Edition was commenced some fifteen years ago and some of it was in type when the War broke out The publication of this Edition is due to my having had the co operation of my son, Professor G P Thomson, who has done most of the work required for its preparation "

The spirit and plan of the new edition are essentially the same as those of the earlier ones, even the numbering of the paragraphs is the same The preface says

We have adopted a decimal notation for numbering the paragraphs, those that were in the Second Edition are denoted by integers, and those dealing with subjects cognate to the original paragraph by this integer followed by a decimal Most, though not all, of the original paragraphs have been retained, a few in shortened form Otherwise little alteration has been made in them beyond replacing the values of the fundamental constants by the more accurate ones obtained since the publication of the earlier editions "

The nomenclature has been changed to accord with modern practice, using 'electron' in place of 'corpuscle' or 'negative ion,' and 'X rays' instead of 'Röntgen rays'

The new volume, in 482 pages, covers the ground of the first ten chapters of the second edition, which there required 290 pages The material of about 240 pages out of these 290 is used in the new edition with only minor changes Thus about one half of the new volume is wholly new material It has naturally been possible to cover adequately the work of the last twenty two years only by restricting the subject matter rather closely to the title "Conduction of Electricity through Gases" instead of dealing with the broader field of electric discharges in gases

In Chapter i, dealing with the conductivity of gases in a normal state, five pages are added covering recent research on the penetrating radiation "coming from the sky" In speaking of the uncertain origin of these radiations it is stated (p 12) "It would be one of the romances of science if these obscure and prosaic minute leakages of electricity from well insulated bodies should be the means by which the most fundamental problems in the evolution of the cosmos had to be investigated"

The subject of the mobility of ions, which occupied 38 pages, or about half of Chapter ii in the second edition, is now treated in a separate chapter of 108 pages Eleven methods, including the recent ones of Tyndall and Grindley, and of Laporte, are discussed at length, and there follows an excellent treatment of the theory of mobility and its dependence on pressure, temperature, impurities, and the sizes and masses of the ions

Ten pages are devoted in Chapter vi to an account of Thomson's early work on positive ray analysis, followed by 14 pages on Aston's further development of the mass spectrograph and a discussion of isotopes In Chapters vii and viii, ten pages are given to Millikan's determination of e and five pages to C T R Wilson's cloud tracks of ions

Chapter ix, on ionisation by incandescent solids, has been increased from 40 to 61 pages, much less than might seem warranted by the great development in this field After dealing with the effect of space charge on pure electron currents in high vacuum, there follows on p 374 a discussion of the effects to be attributed to the initial velocities of the electrons from the cathode This is treated as a problem of the diffusion of the electrons It seems to the reviewer that the concept of diffusion of electrons in high vacuum (such as that for which the 3/2 power law applies) is not appropriate in this case, and that the only proper treatment is one of the type that has been given by Epstein, Laue, Fry, and the reviewer in various publications on this subject

As the plan of the book is an application of the classical kinetic theory to the phenomena of gaseous conduction, it is natural that no attempt is made to treat the collisions of electrons with atoms or ions from the point of view of the quantum theory Critical potentials are mentioned practically only on p 472 in a comparison of Townsend's data on ionising potentials with those obtained by the Frank and Hertz method Quanta are mentioned only in connexion with photoelectric effects involving the Einstein equation On pp 57 59, a theory is derived for the energy which an electron loses in colliding with a molecule, based upon the classical assumption that an electron in the molecule has a definite period of vibration, so that the impinging electron transfers a variable amount of energy to the vibrating electron

The present value of the classical methods is, however, in general amply demonstrated by this book, and by the numerous cases where the more rigorous methods of the new mechanics have not yet been or cannot yet be applied to the solution of practical problems The book is to be thoroughly recommended not only to those interested in the historical development and the present status of the subject matter, but also to those who still desire to have 'physical pictures' to aid them in understanding phenomena IRVING LANGMUIR

Our Bookshelf

An Introduction to Organic Chemistry By Prof Alexander Lowy and Dr Benjamin Harrow Second edition Pp xiv+407 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd) 15s net

THE second edition preserves the general character of the original Although not sufficiently didactic for use as a vade mecum for junior students of organic chemistry, it should be of value as a supplement to lecture courses and experimental work Some of the numerous tables and summaries are possibly overburdened with detail, while in other instances the treatment is unduly laconic For example, the isomerism of maleic and fumaric acids is indicated by means of two formulæ with a footnote "It is suggested that the instructor show this type of isomerism with the Kekulé [sic] models" An exposition of spatial isomerism, even with the aid of an instructor and Kekulé models, leaves something to be desired

Although the carbohydrate chapter has been revised and enlarged, there is no reference to the δ oxide formula for glucose, moreover, the repre-

sentation of lactose with a formal aldehyde group is somewhat misleading The book contains a number of useful indications of the connexion between organic chemistry and medicine, pharmacy, dentistry, agriculture, and the biological sciences There is adequate mention of up to date methods of preparing various organic substances in common use, but it is surprising to find, in a modern text book, the terms 'diatomic,' 'triatomic,' and 'polyatomic' applied to alcohols The type and paper are of excellent quality, the portraits of eminent organic chemists, however, are not well reproduced J R

Laboratory Methods of Inorganic Chemistry By Heinrich Biltz and Wilhelm Biltz Authorised translation by William T Hall and Arthur A Blanchard Second edition Pp xv+261 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1928) 12*s* 6*d* net

The first edition of Biltz was very favourably received, and the present edition is an improvement on the previous one New preparations have been added and the older ones revised The short theoretical sections are also very good, especially that on the periodic system, in which atomic structure is included In most undergraduate courses the amount of practical inorganic chemistry, apart from qualitative analysis, is usually much too small in comparison with the practical organic chemistry, and there is sometimes a danger that the course will lack balance and become one sided Any idea that inorganic preparations do not offer so much scope for manipulative skill as those in organic chemistry will quickly be dispelled by looking through the present volume, in which a number of more difficult preparations are included These are in many cases suitable for students who have completed an ordinary course and wish to do more advanced work without actually embarking on research

The book will also be found most useful by students beginning research in inorganic chemistry, and by teachers who wish to introduce inorganic preparations into the more advanced courses It may be recommended to all these as the only work of its standard in existence When the large amount of material presented is taken into consideration, the price is very reasonable indeed

Che cos' è l' elettricità? Per Giovanni Giorgi (Collezione Omnia, 8) Pp 136 (Roma Paolo Cremonese, 1928) 6 50 lire

The latest developments of physical theories point not only to the possibility of a complete change in our conception of the nature of matter, but also in our views of causality and natural law They are no longer purely mathematical and experimental Speculations are being made in regions formerly regarded as metaphysical and outside the limitations of human knowledge No one can say where these speculations will lead us Recent theories, however, are becoming more acceptable to the average physicist Electrons and protons appearing as energy centres in so-called material waves remind us of the vortex rings which were much studied fifty years ago

G Giorgi, in this interesting little book, gives us a clear résumé of the opinions held as to the nature of the phenomena of electricity, beginning with Du Fay in 1733, and ending with de Broglie, Schrödinger, Dirac, and Heisenberg Practically no knowledge of mathematics is assumed, so this book will be appreciated by the layman as well as by the scientific worker No one can claim to have a general knowledge of science who is ignorant of these theories If they are as important as many physicists believe them to be, then the sooner they come up before the general tribunal of mankind the better

Leaf Mining Insects By James G Needham, Stuart W Frost, and Beatrice H Tothill Pp viii+351+5 plates (London Baillière, Tindall and Cox, 1928) 27*s* net

The authors mention that the object of this book is to provide a non technical introduction to leaf-mining insects, an account of their biology and lists of miners, together with their host plants Four orders of insects, namely, Coleoptera, Lepidoptera, Hymenoptera, and Diptera, include species which have developed leaf mining habits in their larval stages This type of behaviour attains its greatest development in Lepidoptera, and about one half of the volume is consequently devoted to these insects The various grades of mining habits are discussed, and the correlation between structure and function clearly stressed in different types of larvæ Although the subject is a specialised one, the knowledge brought together by the authors shows that the study of leaf miners offers many features of interest to the ecologist and to the student of adaptation At the same time, the field naturalist and economic entomologist will find the book of material help in the identification of the species found, more especially in North America The subject matter is well arranged, the illustrations are for the most part adequate, and there is a useful bibliography provided at the end We can recommend the book as a useful introductory manual

The Cellulose Lacquers a Practical Handbook on their Manufacture By Dr Stanley Smith Pp ix+145 (London Sir Isaac Pitman and Sons, Ltd, 1928) 7*s* 6*d* net

The cellulose lacquer industry is one of great importance, and the manufacture and applications of these materials are advancing at a rapid rate The present manual is written from the practical point of view The style is often rather discursive, and although the author remarks that he will avoid technical terms so far as possible, this is no reason why he should not spell correctly those which he uses, 'phthallate' occurs several times The account covers the whole subject, including raw materials, formulæ, plant, pigments, methods of application, and the industrial applications The book is well printed and illustrated, and it will be found useful to those actually engaged in the industry

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

A Proposed Modification of Einstein's Field-Theory

IN previous issues of NATURE[1] mention has been made of Einstein's recent field theory, intended to combine in a compact geometrical model the mathematical representation both of gravitation and of electromagnetism.

The original essay of Einstein is based upon a special covariant derivation and absolute parallelism (already introduced by Prof. Weitzenböck and, independently, by Prof. Vitali), and leads to the construction of two sets of relations, one of which corresponds exactly to Maxwell's theory, whilst the other reproduces the celebrated Einstein's gravitational equations, though only to a first approximation.

I have remarked that Einstein's model may be more completely and satisfactorily attained without abandoning the usual lines of absolute calculus, and, above all, rigorously accounting for both Einstein's and Maxwell's equations. A full exposition of this method with correlated mathematical developments is now in print in the Berliner *Sitzungsberichte* (by the kind transmission of Prof. Einstein). I take the liberty of resuming here my improvement, Einstein's procedure itself having been outlined some weeks ago in the article by Prof. Eddington already quoted.

The support of the model is still the space time V_4, that is, a Riemannian four dimensional manifold which embodies space and time; but something is to be added to the topological attributes of this fourfold continuum, and to the expression of its metrics

$$(1) \qquad ds^2 = g_{\mu\nu}dx^\mu dx^\nu$$

in general co ordinates x^0, x^1, x^2, x^3.

To obtain a convenient filling we first recall some fundamental notions of differential geometry. A direction function of the point (x^0, x^1, x^2, x^3) may be defined by means of the corresponding parameters $\lambda^\nu (\nu = 0, 1, 2, 3)$, that is, four numbers which are proportional to the increments dx^ν of the x^ν in the given direction, the factor of proportionality being fixed (if we exclude the directions of zero interval along which $g_{\mu\nu}dx^\mu dx^\nu = 0$) by the quadratic condition

$$(2) \qquad g_{\mu\nu}\lambda^\mu\lambda^\nu = 1.^{2}$$

The differential equations

$$\frac{dx^0}{\lambda^0} = \frac{dx^1}{\lambda^1} = \frac{dx^2}{\lambda^2} = \frac{dx^3}{\lambda^3}$$

define a family of lines, called congruence, such that a line of the family passes through every point of the V_4 in the direction λ.

Now we may provide our V_4 with a fourfold diagram, *world lattice*, by introducing not only one only, but also a set of four congruences which intersect each other at right angles. If their parameters are denoted by $\lambda_i{}^\nu$ (i order suffix, ranging from 0 to 3), we must have, combining (2) with the condition of perpendicularity,

$$(3) \qquad g_{\mu\nu}\lambda_i{}^\mu\lambda_k{}^\nu = \delta_{ik} \qquad (i, k = 0, 1, 2, 3),$$

where δ_{ik} has the usual meaning (0 if $i \neq k$, and 1 if $i = k$).

When the $g_{\mu\nu}$ are given, equations (3) represent $4 \cdot 5/2 = 10$ conditions to be satisfied by the 16 parameters $\lambda_i{}^\nu$. But, as the $g_{\mu\nu}$ are exactly as many as the equations (3), we may also regard (3) as the definition of the $g_{\mu\nu}$, that is, of the metrics of V_4, the 16 quantities $\lambda_i{}^\nu$ being taken at will, with the only restriction that the determinant $\|\lambda_i{}^\nu\|$ does not vanish. It is, more over, very easy to solve explicitly the (linear) equations (3) with respect to the $g_{\mu\nu}$. Denoting by $\lambda_{i/\nu}$ the reciprocal element of $\lambda_i{}^\nu$ in the determinant $\|\lambda_i{}^\nu\|$ (that is, the algebraic complement, or minor, of $\lambda_i{}^\nu$, divided by the determinant itself), we have

$$(3') \qquad g_{\mu\nu} = \sum_0^3{}_i \lambda_{i/\mu}\lambda_{i/\nu}.$$

Our task is to show that the 16 quantities $\lambda_i{}^\nu$ (and, with them, all the features of world lattice) may be determined by means of the field equations. From a mere formal point of view such a requirement is quite allowable. Indeed, the gravitational equations are in number *ten* (as many as the $g_{\mu\nu}$). On the other hand, Maxwell's system involves (besides the $g_{\mu\nu}$) the six elements $F_{\mu\nu}$ of an anti symmetrical tensor, which define simultaneously the electric and the magnetic force. The system is formed by eight equations, bounded, however, by two differential identities, so that only *six* are independent; and effectively they are able, as is well known, to determine the $F_{\mu\nu}$ uniquely from their initial values. As $10 + 6 = 16$, we have exactly as many equations as there are $\lambda_i{}^\nu$. But in what sense and manner do these equations contain our $\lambda_i{}^\nu$ (and no other unknown quantity)?

The answer is obvious, or even forced, in regard to the gravitational equations, for they are essentially partial differential equations of the second order in the $g_{\mu\nu}$; hence, by (3'), we may regard them as well as 10 differential equations for the $\lambda_i{}^\nu$, which contain, moreover, like the Maxwellian equations, the six components $F_{\mu\nu}$. In order to get relations involving only the geometrical quantities $\lambda_i{}^\nu$, we must connect in some way the F's with the λ. From an abstract point of view this may be done arbitrarily, with the only condition that the six new equations, thus arising from the Maxwellian ones, are independent one of another, and, together, of the ten former, which implies, among other things, that the $F_{\mu\nu}$ cannot be combinations of the $g_{\mu\nu}$ alone.

I propose to put

$$(P) \qquad F_{\mu\nu}\lambda_i{}^\mu\lambda_k{}^\nu = \upsilon\sum_0^3{}_l \frac{d\gamma_{ikl}}{ds_l},$$

where υ denotes a constant, $\frac{d}{ds_l}$ the operator $\sum_0^3{}_\nu \lambda_l{}^\nu \frac{\partial}{\partial x^\nu}$, and the γ_{ikl} are the *Ricci's coefficients of rotation* of the set of congruences to be determined. Their explicit expressions are well known; at any rate it may be remembered that they follow immediately from the equations

$$(4) \qquad \gamma_{lik} - \gamma_{lki} = \sum_0^3{}_\nu \lambda_{l/\nu}\left(\frac{d\lambda_k{}^\nu}{ds_i} - \frac{d\lambda_i{}^\nu}{ds_k}\right),$$

$$(5) \qquad \gamma_{ikl} + \gamma_{kil} = 0 \qquad (i, k, l = 0, 1, 2, 3).$$

I shall not enter into details concerning the features of the position (P) itself, or of its consequences as transformer of the Maxwellian equations in pure geometrical ones. I content myself with a hint to the limiting case of empty space.

It has been a starting point in the original discovery of Einstein's gravitational equations (and was after-

[1] Compare especially the brief but striking account by Prof. Eddington in NATURE of Feb. 23, pp. 280-281, and the letter from Messrs. Wiener and Vallarta in the issue of Mar. 2, p. 317.

[2] Since the ds^2 of general relativity is indefinite, the condition (2) may very well introduce imaginary λ's. We allow them here for brevity; but in my paper it is shown how any appearance of imaginaries may be avoided in the very appropriate manner systematically worked out by Prof. Eisenhart in his "Riemannian Geometry" (Princeton University Press, 1926).

wards mathematically proved by Serini) that, if the energy tensor is zero throughout all space, and singularities are excluded, this is necessarily Euclidean Now what will be the set of congruences in such an empty space, that is, a space where not only material masses, but also electromagnetic forces are absent ?

Our position (*P*), for $F_{\mu\nu}=0$, leads almost immediately to the conclusion that, *in empty space, the world lattice is Cartesian* Any intervention of material or electric phenomena carries, on the contrary, some distortion of world lattice with it

The Primary Process in the Formation of the Latent Photographic Image [1]

IN two brief notes to NATURE (120, 441, 1927 121, 865, 1928), it was shown by one of us that the mechanism taking place during the formation of the latent photographic image in silver bromide emulsions must be closely connected with that causing the photo-conductivity effect (that is, the decrease of resistance on illumination) in silver bromide prepared free from gelatin and other substances present in commercial emulsions

The complete building up of the latent image is now generally considered as divisible into two stages (1) The absorption of light by silver bromide and the immediate resulting mechanism, and (2) complicated chemical reactions between the product of the light action and the other substances, such as gelatin, present in the emulsion The first of these stages consists in the decomposition of silver bromide into silver and bromine and is known as the *primary process*, whilst the latter or *secondary process* is supposed to be concerned with the removal of the bromine (thus leaving metallic silver) due to its taking part in the chemical reactions which follow the primary process The problems arising in this secondary process appear only to be open to attack by chemical methods, but the first is susceptible to physical methods of attack

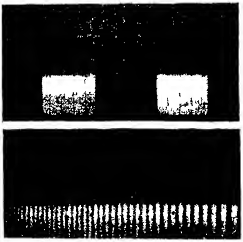
In the light of modern knowledge, the function of the light in decomposing silver bromide is to transfer the valency electron back from the bromine to the silver, *during its passage it is momentarily a free electron*

If, when light shines on silver bromide, there is no escape for the bromine set free (this condition holds when silver bromide is fused between quartz plates), then no permanent change in the substance can take place, and whatever exposure the salt may be given it will be in precisely the same state after the exposure as it was before But even if there is no actual decomposition, the mechanism of transfer of valency electrons still takes place when the silver bromide is exposed, only in this case there is an equilibrium existing between the rate of their liberation from the bromine ions and the rate at which they go back again It is these liberated valency electrons which cause the photo conductivity effect

Thus the photo conductivity effect in layers of silver bromide made under conditions such that the bromine cannot escape is simply an expression of the primary photographic process, isolated completely from all secondary chemical processes Since the primary process is the part chiefly concerned with the absorption of light, this explains completely why the spectral sensitivity of the photo conductivity effect in silver bromide is so similar to that of the finished silver bromide emulsion, as the previous communication showed

If these photo currents are simply due to the liberation of valency electrons, as in the photographic process, then, since we know that the latter can occur in an extremely short time, it is to be expected that these currents will start to flow almost instantaneously with the illumination of the silver bromide

If a melt of fused silver bromide containing electrodes connected in circuit with a source of E M F and a current measuring instrument be illuminated, very complicated effects will in general be observed, indeed, sometimes a strong *negative* effect (*i e* decrease of current on illumination) is the result The causes of these complications cannot be discussed here, but one of the chief difficulties, now overcome, has been to isolate the almost instantaneous electron liberation from all complications, such, for example,



A

B

FIG 1 —A Two exposures one of 0 46 sec and the other of 0 45 sec B A succession of exposures from 0 02 sec on the left to 0 06 sec on the right the dark vertical lines are 0 1 sec apart and the fine lines 0 01 sec apart

as those which occur at the electrodes The latter may be eliminated by using silver electrodes and shielding them from the light

A word of explanation is necessary in connexion with the accompanying photographs (Fig 1), the object of which is to show how nearly instantaneous is the photo current, due to liberated valency electrons, when isolated from all other effects A source of light was arranged so that a beam passed through a thin layer of silver bromide fused in between quartz plates and then fell on one half of a slit, behind which was a moving kinematograph film Electrodes in the solidified layer of bromide were connected to a valve amplifier which magnified the photo current about one hundred thousand times, and was connected to an Einthoven string galvanometer The image of the string was focused on the other half of the moving film, along which timing marks were produced at intervals of 0 01 second Thus the moment of illumination of the silver bromide was registered by the photographic impression on one half of the film (the lower half in the figures), whilst the time of appearance of the photo current as given by the galvanometer deflection could be read off from the other half

The film shows that the photo current starts within about 0 001 second of the illumination and is completely established within 0 03 second Since this is approximately the lag of the galvanometer in the

[1] Communication No 72 from the British Photographic Research Association Laboratories

valve circuit used, the probability is that the effect reaches its final value very much quicker than this, and there seems no reason to doubt that it *starts* instantaneously with the illumination as in the true photoelectric effect

Incidentally, the film is an illustration of a single beam of light producing *only* the primary part of the photographic process in one layer of silver bromide and the *whole* photographic process (primary + secondary, giving latent image) in another layer, *i e* in the emulsion on the film

We have further observed these photo currents with an intensity of ultra violet light which was so small that it only just produced a developable effect on a plate of H and D speed 550 in 1/25 second, *i e* the effect is observable in the region of normal photographic intensities

Electron Reflection from Cobalt, and Electron Waves

MEASUREMENTS by a number of observers of the velocity distribution of the electrons leaving the surface of a metal under bombardment by a beam of electrons of known velocity, have shown that a part of the secondary electrons have the primary velocity, the rest having, in general, a lower velocity No attempt appears to have been made to resolve the secondary emission into its two components when the secondary emission is studied as a function of the velocity of the primary electrons This is a preliminary account of the results of such an experiment Previous work (Davis, *Proc Nat Acad Am*, **14**, p 460, 1928) has shown that the total secondary emission from cobalt, when plotted against the primary velocity, exhibits a number of sharp maxima and minima extending over an unusually large range of voltages This fact made it seem an ideal subject for the present type of investigation

The procedure was to measure the total secondary emission (including both groups of secondaries) and then to apply such a retarding potential that only those electrons having within a few volts of the energy of the primary electrons could reach the collector The difference between the two values so obtained for each primary velocity should give the magnitude of the group having the lower range of velocities The results of the experiment are shown in Fig 1 Here the ratio of secondary to primary currents as ordinates is plotted against the observed accelerating potentials Curve *A* shows the total secondary emission Curve *B* represents the 'reflected' electrons (those electrons leaving the target with velocities within two equivalent volts of the primary velocity), and curve *C*, the difference between corresponding ordinates of *A* and *B*, shows the behaviour of the low velocity group It appears that, for cobalt at least, the important maxima of the total secondary emission curve may be attributed to the 'reflected' electrons

The critical dependence of the number of 'reflected' electrons upon the primary velocity provokes speculation as to the nature of the phenomenon A number of unsuccessful attempts to connect the maxima in secondary emission curves with atomic characteristics having been made in the past, it seems possible that a more fruitful line of reasoning might be one analogous to that used so successfully by Davisson and Germer (*Phys Rev*, **30**, **705**, **1928**) in explaining the reflection of electrons at the face of a single crystal of nickel The observations being reported on were made with a polycrystalline cobalt target rather than a single crystal Hence electrons might be expected to suffer diffraction at its surface in a manner similar to the diffraction of X rays in the so called 'powder' method In this case the Bragg formula

$$n\lambda = 2d \cos \theta$$

should be satisfied, where n is the order of the diffraction beam, λ the de Broglie wave length

$$\left[\lambda = \frac{h}{mv} = \left(\frac{150}{V}\right)^{\frac{1}{2}}\right]$$

of the electrons, d the spacing of the diffracting planes, 2θ the angle between incident and diffracted beam, and V the velocity of the incident electrons in equivalent volts

The longest wave length which can be diffracted by a set of planes with a spacing d will be $\lambda_{max.} = 2d$ From the geometry of the apparatus it follows that,

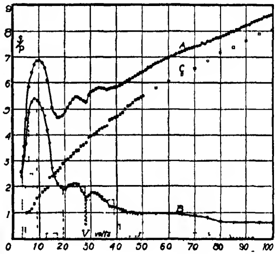

FIG 1

in order to reach the receiver, secondary electrons must leave the target at an angle with the normal not greater than 60° Applying the Bragg formula within this angular range to the most important sets of planes known for cobalt in the hexagonal close packed form, it is possible to compute ranges of electron velocities, or bands on the wave length scale, which should be sent back into the receiving cylinder by constructive reflection These bands are shown in the figure, their relative intensity having been taken as the known relative intensities of the corresponding X ray reflections

It will be seen that by this simple and obviously only approximate procedure, a fair correspondence is obtained between three groups of bands and the most prominent maxima of the secondary electron curve The degree of correspondence shown was obtained by shifting the observed curve to the right by a matter of 4 to 5 volts, which is just about the observed thermionic work function of cobalt It should be pointed out that such a small shift is not in agreement with Davisson and Germer's adjustment of their own observations, they having found that an assumed surface potential of about 18 volts was the most satisfactory

Bethe has derived approximately the same large value from theoretical considerations In spite of this difference, it seems worth while directing attention

to what can be done in the way of accounting for secondary electron maxima of cobalt on the basis of electron waves Attempts to correlate, in a similar way, the maxima observed with other metals are now being made

Temperatures of Positive Ions in a Uniformly Ionised Gas

A GAS through which a current is passing may be considered as a mixture of three gases—neutral molecules, electrons, and positive ions In regions of relatively small field and space charge, each of these gases will show an approximate Maxwellian distribution of energies among the particles, that is, will be in temperature equilibrium within itself, but each gas will have a different temperature Even at gas pressures so high as a millimetre of mercury, and in an almost field free space, the temperature of the positive ions will be very much higher than the temperature of the neutral molecules with which they are continually colliding The only available source of energy of random motion appears to be the electron gas, which is at a still higher temperature L H Thomas (*Proc Royal Soc*, A, **121**, 464, 1928) derives formulæ for the interchange of energy between particles interacting according to the inverse square law and uses them to explain the rapidity with which a Maxwellian distribution of velocities is set up within an electron gas They may also be used to calculate the temperature of the positive ions from the temperature of electrons and the pressure of the gas in a field free space

For comparison with the calculations, data of mine on the width of lines emitted from the negative glow of the helium arc will be used (*Phys Rev*, **32**, 918, 1928) The following assumptions form the basis of the calculations

1 The positive ions acquire energy solely from the energy of random motion of the electrons

2 They lose energy by collision with the molecules of neutral helium at a rate which may be calculated from kinetic theory

The rate at which the positive ions acquire energy from the electrons is calculated from formulæ (4 22) and (4 23) of Thomas's paper, assuming all the electrons to have the most probable velocity and neglecting the velocity of the positive ions In calculating the loss of energy to the neutral molecules, the latter are taken as stationary and the radius of the ion is taken from the Bohr theory of the helium ion Equating the rate of gain to the rate of loss gives the calculated temperature As the pressures were very roughly measured and the ion temperatures are subject to considerable uncertainty, the data do not warrant making a more exact calculation The comparison is given in Table I

TABLE I

Electron Temp (Volts)	Electron Density (Electrons/c c)	Gas Pressure (mm of Mercury)	Ion Temp Calc (Volts)	Ion Temp Obs (Volts)
0 66	$3\ 2 \times 10^{12}$	1 1	0 12	0 07
0 52	$7\ 5 \times 10^{11}$	0 5	0·11	0 10
1 2	$2\ 1 \times 10^{12}$	0 4	0 14	0 14
0 87	$3\ 4 \times 10^{12}$	0 4	0 22	0 10
0 86	$1\ 8 \times 10^{12}$	0 25	0·20	0 14

That the calculated values are consistently high may be due to neglecting the shielding effect of the gas on the interaction of the charged particles or to taking too small a radius for the helium ion The agreement is within the error of calculation and measurement It is interesting that even the order of magnitude is correct, as all direct measurements of interaction between positive ions and gas molecules give values which differ from those calculated from the kinetic theory Harnwell (*Phys Rev*, **31**, 634, 1928), for example, found that the loss of energy of alkali ions of high velocities passing through helium was only a few per cent of that expected Ramsauer and Beeck (*Ann der Physik*, **87**, 1, 1928) made measurements on the same ions which extended to velocities so low as one volt, and found that the effective radii of interaction were always larger than the predicted radii and increased rapidly as the velocity decreased The radius of the helium ion is so small compared to the radius of the helium atom that doubling or tripling it would have only a small effect on the calculated temperatures of Table I Interesting results of the calculation are that the ion temperature should increase with decreasing electron temperature and increase with increasing electron concentration The range of variation of electron density and temperature in these experiments is too small to test these conclusions

Selenium and Cathode Rays

IN the course of some experiments upon the light sensitive properties of selenium, evidence has been obtained by me of what appears to be a direct action of cathode rays upon the grey crystalline form of that substance

The cell was prepared by condensing vapour of heated selenium upon a gold grid It was placed in a glass tube which could be exhausted and so arranged that a pencil of cathode rays fell upon the crystals after passing through the openings in an earth-connected metal gauze tube which completely surrounded the cell The cell itself was also connected to earth

Precautions were taken to absorb all mercury vapour that might otherwise have diffused from the pump into the exhausted vessel and provision was also made for the elimination of moisture

A simple plan was devised to detect the effect, if any, of the slight luminosity due to fluorescence that appeared when the discharge occurred, and a series of control experiments were made with all conditions similar except that a plain gold grid *without selenium* was placed within the earthed gauze screen

The anode was sealed into a side tube behind the cathode and at a distance of about one inch from it

It was found that, although the selenium cell used was markedly sensitive to light, no appreciable effect whatever was produced by the slight luminosity of the tube due to fluorescence either of the walls or of the glass strip upon which the selenium was deposited

When the cell was exposed to cathode rays, however, a rapid diminution of resistance occurred which could be widely varied by deviating the rays with a magnet

The cell exhibited many of the effects observed when light was shone upon it but the lag was less Its resistance somewhat increased at first, due to the bombardment, so that the 'dark current' was reduced This effect was not permanent, but

frequently resulted in an unusual rise of the 'dark current' value after the discharge had ceased

It is improbable that the marked action of the cathode rays can be attributable to the production of X rays in the selenium, because in that case the decrease of resistance and recovery would have been far less and taken place much more slowly

Experiments made by enclosing the cell in an earth connected brass tube provided with an aluminium window 3/1000 inch thick looking towards the cathode, but through which the cathode rays could not penetrate, produced a very slight and gradual decrease of resistance, this and the slow increase on cessation of the discharge are typical of the action of X rays upon selenium In this case the X rays were generated at the aluminium window

Under these conditions, and with a P D of 60 volts across the cell, the reading of the microammeter rose slowly 10 microamperes, whereas on replacing the aluminium window by one of metal gauze the deflection suddenly increased to 250 microamperes and fell rapidly, with a slight lag, before returning to the 'dark current' value, when the cathode rays were momentarily allowed to impinge upon the selenium The alternate spark gap at the induction coil was two inches, and the only luminosity appearing in the tube was that due to fluorescence

Deposition and Surface Tension

THE publication of a lengthy study of related phenomena by L K Luce (*Ann de Phys*, February 1929, pp 167 257) prompted this preliminary report of similar results found by the same as well as other methods during the last two years, under the direction of Prof Gerlach, in Tübingen

Iodine deposits resulting from directional molecular rays, as in the Dunoyer experiments (*C R*, **152**, 592 594, 1911), showed that those of a homogeneous nature are only possible on smooth, clean, perfectly annealed surfaces On a surface, which was etched, rubbed, or scratched in any particular portion, crystal nuclei started growing immediately A long series of experiments on glass and silver surfaces of various convex and concave curvatures, showed that deposition and chemical attack are a function of the curvature, cold working, or, in short, a function of the surface tension of the underlying surface Reboul's early work (*C R*, **155**, p 1227, 1912, and **156**, p 1376, 1913) on the chemical attack of silver rods of different curvatures, as well as Luce's later work, give functional curves which are not unlike those obtained in Tübingen

That the factors of adsorption and diffusion play a part in these experiments, as Luce remarks in his work, we find very probable Adsorption experiments on glass surfaces of known curvature carried out on a long series of glass tubing, and on plane glass of different varieties, show similar functional relations to the results for deposition and reaction Such thin layers can be weighed with a microbalance For plane and slightly curved surfaces the sorption layer does not exceed monomolecular thickness, which agrees with the theory of Langmuir (*Zt f Elektrochemie*, **26**, p 197, 1920), but with increasing curvature the adsorbed layer increases In capillaries 0 8 mm in diameter and less, the adsorbed layer is of the order of seven molecules in thickness Where chemical attack plays the primary rôle, diffusion is of greater importance Experiments on single crystals of silver are being carried on, and it is hoped that they will throw light on the nature of diffusion

Invisible Oxide Films on Metals

IN his letter in NATURE of April 13, page 569, Dr F H Constable adduces interesting evidence bearing upon the formation of invisible oxide films on copper at room temperatures In fairness to Dr W H J Vernon, whose researches in this field are not mentioned by Dr Constable, it should be stated that, working in my laboratories under the auspices of the British Non Ferrous Metals Research Association, he demonstrated the formation of invisible oxide films on copper, and studied their inhibiting effect on tarnishing

Dr Vernon's results were communicated to the Atmospheric Corrosion Research Committee in 1923 though they were not published until three years later (*Journal of the Chemical Society*, p 2273, 1926) Invisible protective films were obtained by exposure to air at room temperatures, while at higher temperatures (from 50° C upwards) certain quantitative relationships were established A critical thickness of film was recognised, *within the invisible range*, below which protection was no longer afforded, it was concluded that this corresponded with the unit lattice of cuprous oxide Later (*Transactions of the Faraday Society*, **23**, 113, 1927) it was shown by the same worker that under favourable conditions, invisible protective oxide films are also produced at room temperatures upon lead and iron

It is interesting to note that some of Dr Vernon's earlier conclusions are confirmed by the spectrophotometric methods employed by Dr Constable Moreover, it is satisfactory that there is now general agreement as to the part played by the direct oxidation of metals at ordinary temperatures, about which only a few years ago differences of opinion existed

Skull Thickness

WITH reference to Mr Wilfred Trotter's paper, published in NATURE of April 6, the following quotations from Herodotus (Isaac Taylor's translation) may be of interest

"A remarkable Fact was pointed out to me by the People who live on the Spot where this Battle took Place The bones of the slain being heaped apart—the Persians lying by themselves as they fell in their Ranks, and the Egyptians separately also,—the skulls of the Persians are so weak, that you may, if you please, break them in, by throwing a Pebble, while those of the Egyptians are so strong, that you scarcely produce a Fracture by dashing a stone at them"—"I observed also a similar appearance on the Field at Papremis, where lay those slain by Inarus, the Lybian, under Achaemenes, son of Darius."

Croydon

The Volta Temple at Como

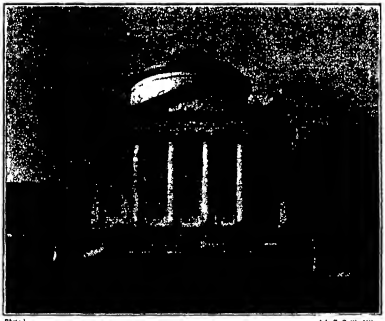
IN the year 1899 the centenary of the discovery of the voltaic pile was celebrated in Como, Volta's native city, by a joint International Electrical Exhibition and a National Exhibition of Silk Products On the morning of July 8, fire broke out in the Exhibition, and the buildings and their contents, including the precious collection of Volta relics, were almost entirely destroyed within the short space of forty minutes

Of the instruments constructed and used by Volta in his epoch making experiments, only a few damaged fragments were recovered By a fortunate chance, Volta's documents were not being exhibited, as the Royal Institute of Lombardy had refused to allow them to be sent to Como The rebuilding of the Exhibition was commenced immediately, and was prosecuted with such vigour that the reopening ceremony took place on Sept 1, less than two months after the fire

A few years later the more difficult problem of the restoration of the Volta relics was attacked energetically and, in view of the apparent futility of the attempt, secretly, by one of Como's citizens, Francesco Somaini, with the help of a small band of earnest coadjutors, and in due course was successfully accomplished No pains were spared and no document or drawing bearing on the subject was left unstudied, so that the resemblance of the reproductions to the original instruments is as close as it is humanly possible to make it Besides having this work done and bearing the cost thereof, Somaini has, also at his own expense, erected the sumptuous Volta Temple, in which the whole of the relics, including Volta's records, the national edition of Volta's works, etc, are now housed

This temple was designed by Frigerio, and is situated close to the shore of the lake It is of incombustible material throughout, and is in the neoclassic style, consisting essentially of a circular court or hall of ceremonies, surmounted by a hemispherical cupola which admits a soft light to the interior On the roof of the building, at each of the four corners, is a pedestal light faced by a griffin The main floor of the temple is approached by two wide lateral staircases, and the doorway has, on either side, recessed statues representing Faith and Science

Within, the recesses between the central court and the outer walls of the building contain glazed cases in which are arranged both the fragmentary remains of the instruments rescued from the fire and the reproductions of the originals The court contains a bust of Volta on a tall column and an ornamental bronze tripod presented by the University of Pavia, where Volta served for several decades as professor and rector



Photo] [A G Gatti Milan
FIG 1 —The Volta Temple, Como

A marble staircase, to the left of the entrance, leads to a gallery which surrounds the central hall and contains the library, manuscripts (including some which Somaini was fortunate enough to discover at Vienna), medals, minor records, etc The cupola is supported by four decorated angular pilasters and eight marble columns On the front of the parapet of the gallery are sixteen plaques giving the most significant dates in Volta's life, and four bas reliefs representing him teaching at the University of Pavia, demonstrating his pile to Bonaparte at Paris, receiving the Emperor Napoleon in Pavia, and prophesying, as he leaves the church at Lazzate, telephonic communication The mosaic paving of the circular hall and of the surrounding recesses is ornamented with marble, onyx, and alabaster, and the framework of the glazed cases in which the exhibits are arranged is of iron or bronze coated with green patina so as to resemble ancient bronzes

The skeleton of the building, including the foundations, is of reinforced concrete, the external ornamentation being chiefly of Aurisina stone and the internal of Musso marble, Viggiù stone, and stucco The structure measures about 20 metres wide by 25 deep, and the height to the apex of the cupola is more than 21 metres The building was commenced in November 1925 and was completed by May 1927

First among the instruments invented by Volta comes the electrophorus (1775), which followed as a natural consequence of the views expressed in his dissertation "De vi attractiva ignis electrici ac phenomenis independentibus," published in 1769 In the three years subsequent to the appearance of the electrophorus, Volta studied, both theoretically and experimentally, the influence of the form on the electrical capacity of a conductor and elaborated the conception of tension or electrical potential These considerations formed the starting point of a thorough investigation into the action of atmospheric electricity, this leading to the invention of the condenser, which is also numbered among the exhibits While developing his ideas concerning electric meteorology and the origin of atmospheric electricity, Volta devised the very sensitive straw micro-electrometers and the electrostatic balance, reproductions of these being among the apparatus shown The various forms of voltaic pile assembled by the inventor from such ordinary household articles as spoons, and water-vessels from bird-cages, are also included

Photo] FIG 2—Interior of the Volta Temple [A C Gatti, Milan

The temple has been placed in the charge of Prof Felice Scolari, in conjunction with the Royal Lombardy Institute, and has been generously provided, also by Somaini, with an endowment fund of 500,000 lire, the income from which is to furnish annual prizes of 5000 lire each, to be awarded to distinguished students of Como or of the canton of Ticino desirous of prosecuting studies in electrical subjects

Physics in Relation to Oil Finding[1]

By Prof A O Rankine

EVIDENCE has accumulated during recent years that physical methods can be used under suitable conditions to facilitate the detection and location of minerals buried under the ground This is a fact of considerable economic importance, having regard to the very great and wasteful expense of indiscriminate boring Even the most careful geological survey often fails to fix with sufficient accuracy the points at which drilling is likely to be successful Here, properly applied, physics may make its contribution to enhance the probability of success

We are not now concerned with the divining rod and similar devices—similar, at any rate, in the respect that they can only be operated by persons specially endowed with certain obscure faculties Sometimes the devices are dressed up to have the appearance of physical apparatus, and the methods are called geophysical, but all have this in common —that they are not capable of being independently checked, and for that reason may safely be ruled out of serious consideration We are dealing with genuine physical methods which depend on the differences of physical properties of underground materials, and produce above the surface reliable indications, the measurement of which may provide valuable information regarding sub-surface structure

It is important to emphasise at the outset that there is no question of physics being employed to the exclusion of geology At the best the problems to be solved are extremely difficult, and the closest possible co operation between the two sciences is essential This alliance is implied in the term 'geophysics,' and for the successful development of this as a practical subject, geophysicists adequately trained both in physics and geology are the ideal personnel Physics alone cannot solve problems of underground structure, whatever may be the efficiency of the method employed, for the unknown factors are far too numerous for a unique solution to be possible The geologist must first indicate the kind of underground structure which is sought, and all the probable conditions under the region to be surveyed, before the physicist can even decide whether any available physical method

[1] Substance of two lectures delivered at the Royal Institution on Feb 21 and 28

has a reasonable chance of being applied with success. Often, owing either to the absence of surface indications of a geological character, or to such indications being misleading because of 'non conformability' of superincumbent strata, the geologist is unable to locate with precision the structures he is seeking. It is in such circumstances that physics has been able to join forces and help to define underground conditions more exactly.

With particular reference to the occurrence of mineral oil, geology provides the information that it is usually associated with salt-domes or anticlines, buried more or less deeply below the earth's surface. A typical salt dome, of which there are numerous examples in Texas, is a sort of underground plateau of rock salt, sometimes with a relatively thin covering of anhydrite, called cap rock, the whole being below an overburden of sands and clays. The superficial area of the roughly circular top of the dome may be several square miles, and its depth may vary from a few hundred to several thousand feet. Oil may be located sometimes at the top of the dome, and sometimes at various levels down its flanks. The earth's surface above and around the dome is usually very flat, and there is little in the way of reliable geological indications to determine their positions.

On the other hand, limestone anticlines, such as occur in south-west Persia, are blunt limestone ridges, perhaps several miles in length and relatively narrow, covered, too, with a thin layer of cap rock, underlying a mixture of alluvium, sand stones, marls, gypsum, and salt. In the upper part of the anticline, just below the cap rock, natural gas may be found; farther down the flanks occurs the crude oil with much gas in solution, and still farther down the flanks salt water. Unlike the conditions relating to salt-domes, however, surface evidence of folding structure is abundant, the general direction of the strike being unmistakable. But, unfortunately, owing apparently to the plasticity of the overburden, these geological indications leave in considerable uncertainty the positions of the summits of the anticlines.

Here, then, is the problem of oil finding from the point of view of physics. It is to locate, within regions already roughly delimited by geological considerations, the position and extent of salt domes and limestone anticlines. Thus the search is not for the oil itself, but for the structures with which it is commonly associated. It is true that some claims have been made of locating oil as such by a method depending on its electrical conductivity, but this is very doubtful, and on theoretical grounds the method is distinctly unpromising. To find the oil itself is not asked of the geophysicist; if he can locate the salt dome or the anticline with enough precision, it will always be worth while to drill.

The physicist thus has to consider what properties of these structures are likely to provide surface indications capable of physical measurement and interpretation. Caution is necessary in this respect, having regard to the unfortunate tendency to generalise geophysical methods. These have been enumerated in Prof Eve's interesting article in NATURE last year.[2] Although various claims have been made, there exists no convincing evidence that magnetic and electrical surveys have assisted materially in the location of the structures under discussion. Moreover, the magnetic susceptibilities and electrical conductivities of salt and limestone differ insufficiently from those of the surrounding materials to give on theoretical grounds any real expectation of successful application. The only physical properties which have hitherto without doubt provided means of discrimination are the differences of density and elasticity as between the salt or limestone on one hand, and the superincumbent material on the other.

Remarkable success has been achieved by measuring local variations of gravity which depend directly on the differences of density of sub surface materials. The approximate relative densities of salt and clay, for example, are 2.1 and 2.4, and of the cap-rock over a salt dome 2.9. Small though these differences are, the elegant and amazingly sensitive Eötvös torsion balance has been proved capable of measuring the corresponding gravitational effects in the neighbourhood of numerous salt domes in Texas and elsewhere, thereby locating and defining the limits of such domes, some of them deeply buried below the surface. For a lucid account of this beautiful instrument the reader may be referred to papers by Capt Shaw and Mr Lancaster Jones.[3]

The main purpose of this article is to give an account of a relatively new and less well known successful method of locating structures likely to be oil bearing, known as the seismic method. This method can be applied even in rough country, like that in the Persian oil fields, where gravity measurements are too much distorted by surface effects to give reliable indications of underground conditions. It depends not only on the relative densities but also on the relative elasticities of the rocks encountered, or, what amounts to the same thing, the speeds of propagation of longitudinal mechanical disturbances in these media. In the salt dome structures of Texas, these velocities differ considerably, being about 5300 metres per second for the salt, and about 2000 metres per second for the clay and sand overlying the dome. For the limestone structures of Persia the difference is not so marked, the approximate figures being 4700 metres per second in the limestone and 3700 metres per second in the overburden.

One may perhaps digress for a moment to consider the possibility of using direct reflection from a clay salt interface as a means of determining its depth. If a device similar to the remarkable depth sounding machine[4] which has been so successful at sea could be used, the great advantage would accrue that the measurement of the time taken for the sound to go down to the interface and return by normal reflection would enable the local depth to be estimated. But the method is not

[2] 'Geophysical Prospecting.' By Prof A. S. Eve, NATURE, Mar 10, 1928, vol. 121, p. 359.

[3] *Proc Phys Soc*, vol. 35, p. 151 and p. 204.

[4] "The Acoustic Method of Depth Sounding for Navigational Purposes," by the Staff of the Director of Scientific Research, Admiralty, NATURE, Mar 29, 1924, vol. 113, p. 463.

successful in practice, not because of the failure of the interface to reflect, the reflecting power being reasonably great, but because of the enormous damping of vibrations of audible frequency in the upper layers of the earth Trials with an Admiralty echo sounding machine have actually been made in Persia, but the sounds from the hammer proved much too feeble to be heard through the ground on the microphone at any useful distance It is significant also of the poor transmitting power of the ground that the explosion of several hundred pounds of gelignite at half a mile distance was not audible through it as a medium, although it could be heard, of course, very loudly through the air

We are thus faced with the position that great disturbances of the earth's surface, conveniently in the nature of explosions, are necessary effectively to penetrate to the depths at which oil bearing structures are frequently found Also that a seismograph, which will record vibrations of low inaudible frequency, is preferable to the microphone on account of the smaller damping of such vibrations This at once rules out the direct determination of depth, previously suggested, for a sensitive seismograph obviously cannot be operated in the same position as a large explosion which excites the initial disturbance The recording must be done at a 'safe' distance and the depths of the interface at points other than those immediately below the explosion become involved, thus complicating the problem by the change from one to two dimensions

The necessity for using an explosion involves a new difficulty on account of the appreciable time the consequent disturbance of the earth lasts In all cases the reflected disturbance reaches the seismograph *later* than that travelling direct near the surface, since its path is longer Moreover, it is usually small in comparison with the direct waves, and the effects of the latter upon the seismograph at practicable distances last considerably longer than the difference of times of transmission Consequently the reflected effect becomes so much obscured by the larger direct effect as to be unrecognisable The solution to this difficulty lies in the existence in practice of another disturbance associated with the lower (higher velocity) medium, but distinct from the reflected disturbance, which may, at a sufficient distance from the explosion, reach the seismograph *first* Although small, its time of arrival can be readily recognised, since it makes its record on the seismograph *before* the latter becomes violently disturbed by the direct waves That is the essence of the success of the seismic method of revealing underground structure

The phenomenon with which we are dealing is the same as that which has recently been recognised as operative in natural earthquakes Even in near earthquakes, where the curvature of the earth plays no important part, the records of seismographs show preliminary displacements which apparently correspond to 'rays' from the earthquake source which pass from an upper stratum (of low propagation velocity) at the critical angle into a lower stratum (of higher propagation velocity), run parallel to the interface and eventually emerge again at the critical angle to reach the seismograph on the surface This is, of course, an 'optical path' of an extreme character according to the ordinary laws of refraction, but since the initial incidence is at the critical angle, total reflection would occur according to the same laws, and no energy at all would be associated with the path in question Dr Jeffreys[5] has, however, shown that if the problem be treated as one of diffraction instead of simple refraction, the rather curious result emerges that a finite fraction of the initial energy may be expected to reach the seismograph (as is in fact found in practice) at a time which is the same as that obtained by considering the extreme optical path above described This applies to longitudinal disturbances There are in solids, of course, transverse disturbances as well, but these travel more slowly, and need not concern us here, since, as has been already stressed, the question is one of *first* arrivals

Prof Mintrop was the first to recognise the applicability of this phenomenon to the smaller scale problem of the relatively shallow formations in the earth, using artificial explosions instead of natural earthquakes As a result he has initiated a practical system which has been widely and successfully used to determine the depths of such formations To make the method clear, we may take the simple case of two superposed horizontal strata (Fig 1) in which the velocities of com-

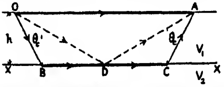


FIG 1 —Explosion at O seismograph at A both on the earth's surface XX is interface between two media of velocities V_1 and V_2 with $V_2 > V_1$

pressional waves are V_1 and V_2 the latter corresponding to the lower medium and being (necessarily) greater than V_1 If an explosion is caused at O and a recording seismograph is located at A, three distinct disturbances reach the seismograph One goes direct from O to A (We are neglecting here the small curvatures which may arise from gradual variation of velocity with depth) Another is reflected at D and arrives at A necessarily later than the former, its path being longer The remaining disturbance arrives at A at a time corresponding to the equivalent path $OBCA$, OB and AC each making the critical angle $\theta_c = \sin^{-1} V_1/V_2$ with the normal In the part BC the speed is the higher velocity V_2, and it is evident that if OA is great enough the total time occupied in transmission may be equal to or even less than that for the direct path OA, which is wholly in the lower velocity medium If so, its small effect will be recognisable on the seismogram in spite of the large disturbance which follows afterwards

(*To be continued*)

Centenary of the Zoological Society of London

THE annual gathering of the Zoological Society of London to receive the Council's report was held on Monday last, April 29, at the meeting room in the Gardens at Regent's Park The occasion signalised the centenary of establishment of the Society by Royal Charter in 1829 Following this compliance with precedent and duty, a centenary celebration, extended and exceptional in character, took place in the Great Hall of University College, the Duke of Bedford, the Society's president, occupying the chair In the evening a private complimentary dinner was held elsewhere, at which foreign and official guests were present, including the Prince of Wales

The Zoological Society itself, as an organised body carrying diverse and onerous responsibilities, has deserved well in endeavour during its centenarian existence, its gardens, moreover, as a prime and essential feature of the original scheme, have long constituted a household word inseparable from national thought and concern But the story of initiation of effort is somewhat older than the century implied by the charter date, 1829, and is comparable, we think, with the early beginnings of other scientific societies which sprang up at the threshold of the Victorian era There were influences tending towards corporate association, such as British exploratory activity, the arrival of natural history specimens, and new views attaching to zoological studies The Linnean Society, instituted in 1788, could not, as time went on, fully satisfy the requirements of zoology In such circumstances, a group of members of that body conceived the idea, in 1822, of establishing a Zoological Club, the object of which should be "the study of zoology and comparative anatomy in all their branches, and more especially as they relate to the animals indigenous to Great Britain and Ireland" The meetings were held in Soho Square, at the former residence of Sir Joseph Banks (who had died in 1820) and home of the Linnean Society

The Club accomplished much important work before its dissolution in 1829 Engaged in the advancement and recognition of zoology, the members were mutually cognisant of the outstanding achievements of Sir Stamford Raffles, the distinguished British colonial governor in Eastern lands, and of the unique and extensive zoological collections he had brought together On returning permanently to England in 1824, Sir Stamford suggested to Sir Humphry Davy, the president of the Royal Society, a plan for the formation of a zoological society which should combine with the pursuit of science the introduction and domestication of such quadrupeds, birds, and fishes as might be most likely to prove useful for agricultural and domestic purposes

Early in 1825 a circular announcement was made of a proposal to establish a society the object of which would be to attempt the introduction of new races of quadrupeds, birds, or fishes, applicable to purposes of utility, either "in our farm yards, gardens, woods, waters, lakes, or rivers, and to connect with this object a general zoological collection of prepared specimens" The name of Sir Stamford Raffles occurs in this circular, as well as, it is interesting to note, that of the Duke of Bedford Writing round about this date to his cousin, Sir Stamford says "I am much interested at present in establishing a grand zoological collection in the metropolis Sir Humphry Davy and myself are the projectors, and while he looks more to the practical and immediate utility to the country gentlemen, my attention is more directed to the scientific department, it is further expected we may go far beyond the Jardin des Plantes at Paris" Here, adverting again to the members of the Zoological Club it was afterwards (1829) put on record that it was in the impulse originally given by their exertions to the propagation of science more particularly by laying the foundation of the Zoological Society, that their agency could be traced in principles and objects

The scheme outlined briefly above, wide in its interests, and to be regulated by laws drawn up with the concurrence of the members, met with a cordial reception, and by this time (1826) Sir Stamford Raffles was an active, and in all probability dominant, personality in the difficult procedure of inauguration Wisely, the decision was taken to draft a report on the present state and progress of natural history, especially zoology, with an account of the institutions which supplied encouragement on the Continent, and showing the necessity of some similar establishment in Great Britain Next, application was made to the Commissioners of Woods and Forests for a grant of land from the Crown Looking back, we may perhaps picture some perturbation of the official mind respecting so novel a proposition However, all went well, and finally space was allotted in the great demesne of Regent's Park

The first general meeting of the Society was held on April 29, 1826, when Sir Stamford Raffles was unanimously elected president He read an introductory address reviewing the position of zoological studies, detailing also the objects and plans of the embryo institution Soon after, there occurred, on July 5, the death from apoplexy, at the early age of forty five, of this notable president and man of affairs Sir Humphry Davy, in offering tribute, said of him that 'having lost one splendid collection by fire he instantly commenced the formation of another, and having brought this to Europe, he made it not private, but public property, and placed it entirely at the disposal of a new association for the promotion of zoology, of which he had been chosen president by acclamation" The following year the Marquess of Lansdowne was elected to the presidential chair, retiring in 1831 The fellowship roll comprised then 2000 names In 1829 the crowning of effort came in the grant of a charter by King George IV

Through limitations of space we must leave at

this point reference to the activities of the immediately succeeding years as regards both the Gardens and the Society Some idea, however, of the achievements which had marked the close of the nineteenth century can be formed by a perusal of Mr H Sherren's interesting volume on the Zoological Society

The establishment enjoyed special advantages during the secretaryship of Dr P L Sclater, covering forty three years Since then the zealous and enterprising work of Dr P Chalmers Mitchell has brought the Society to its present distinctive and high position among the zoological societies of the world As regards staff, it is significant that two women now hold office, respectively, as curator of reptiles and curator of insects Recently, the Society has acquired Whipsnade Park, on the borders of the Chilterns, a derelict estate, destined for conversion into a zoological park, open to visitors

News and Views

BRITISH chemical manufacture since 1913 has not only made rapid strides which have brought it into a position of commercial eminence and have kept it abreast of world wide development, but it has also, at least so far as its leaders are concerned, taken care to consolidate the ground gained and to prepare for further progress by the establishment and endowment of research work At a public meeting arranged by the British Science Guild at the Mansion House on April 24, an account of which appears elsewhere in this issue, Lord Melchett, Sir Frederick Keeble, Mr A B Shearer, and Mr F H Carr showed something of the immensity of the contribution which chemical manufacture is making, especially in Great Britain, to the welfare and prosperity of the people The attention of the recipients is of course distracted at the moment by discussions and political promises of employment, industrial prosperity, peace, and social service Perhaps it was fortuitous, but more probably inevitable, that the very same phrases were used, not of ideals, but of solid accomplishments, by the speakers The artificial silk industry has already, directly or indirectly, given employment to hundreds of thousands of workers, creating its own demand, it has often brought a touch of colour and beauty where there was little that was not drab and formless, and it has probably not been without influence where of late years a notable increase in self respect and self confidence has been apparent The nitrogen industry, in time of war a sharp sword for which the British Empire reached too late, has since been beaten into a ploughshare, which is already firmly harnessed to man's ever increasing material needs, so that the fear of nitrogen hunger has been completely dissolved The drug industry has already been enabled in a multitude of homes to give health where but the spark of life remained, to free the mind from the assaults of the body, and to raise barriers between whole communities and the menace of disease

ALL this has been made possible by basing commercial acumen and technical skill on a firm foundation of fundamental research The chemical industry is a structure which must be designed elastically, in order that it may rest securely and continue to grow on a base which is not only continually extending, but also may at times be found deceptive in its appearance, as researchers probe more and more deeply into the origin and meaning of things It is to the credit of British industry and to that of the State that provision has been made for such investigations to be carried on both in the industrial and in more purely academic laboratories Scientific research of many kinds is even more than a base, it is a frame whereby existing industries are kept virile and progressive, and around which may be built a new industry We cannot enter into a discussion regarding the precise relation of our chemical industries to the various articles of political faith, but we can at least point out three ways in which individual or political action can help to maintain our industry and pave the way for further successful advances We hope that our fellow citizens will never permit themselves to forget the vital position which modern chemical manufacture occupies, not only in determining the prosperity of nations, but also in alleviating human suffering and in increasing the comforts of life Further, we hope that they will use their influence, in whatever way seems to them proper and effective, to secure that those industries shall be nurtured in their infancy, fed with men and women of sound training, and encouraged in their growth Finally, although we should not contemplate with equanimity an entire Cabinet of chemists, we hope that the experience and advice of our pioneers in science and the scientific foundation of industry may be given yet greater weight in the counsels of the nation

A LARGE and representative assembly attended the centenary celebration of the Zoological Society, held on Monday last in the Great Hall of University College, London The Duke of Bedford, president of the Society, occupied the chair, supported by members of Council and those who were designated to convey congratulations on behalf of British and foreign countries In his introductory remarks the president extended grateful thanks to the delegates who had come from many parts of the world to offer good wishes in person, and express their appreciation of the Society's long continuity of effort Dr P Chalmers Mitchell, secretary, gave an epitome of the scientific work which had engaged the attention of the Society He emphasised that the institution was founded by scientific men, and that their aim was not to be merely exhibitors of animals and entertainers of the public The Society has an obligation to advance zoological studies and is fully mindful of it In parasitology much has been done of practical importance to men and animals An interesting summary was given by Dr Mitchell of the work of the prosector's department. Through the publications of the Society a great body

of original research is carried on and encouraged, and he recalled that one of the obligations is the maintenance of a standard library In physiology, the relations of animals to their environment, or response to different physiological conditions, is receiving attention in the light of modern studies in that field

Sir Charles Sherrington offered felicitations on behalf of the Royal Society, M Charles Gravier, for the Paris Academy of Sciences, Zoological Society of France, and the Paris Museum of Natural History, Herr H H Dieckhoff (representing the German Ambassador), speaking in excellently phrased English, claimed that Germany has always been happy to assist in the Society's pioneer work, which has brought rich compensations to knowledge Dr Casey Wood, speaking for the Smithsonian Institution, Washington, referred to a message just to hand from its secretary, Dr C G Abbott, who, he thought, represented the natural history institutions of his country The message ran "It is my desire to extend to you the greetings and best wishes of our organisation overseas The Smithsonian Institution has had close and pleasant affiliation with the Zoological Society of London It is my sincere wish that your Society may grow and prosper equally in the coming hundred years as it has in the century that has elapsed" Dr Jordan, Royal Academy of Sciences, Amsterdam, expressed "deep and proud respect" Prof Cossar Ewart and Prof A F Dixon, representing respectively Scottish and Irish institutions, offered congratulations The proceedings, which were worthy of the great Society, closed with a vote of thanks to the Duke of Bedford, proposed by Sir John Bland Sutton

An instructive discussion took place in the House of Lords on April 25 on the proposed large power station in Battersea The principal objection to this station is the probable large emission of sulphurous fumes from the proposed chimneys, which will be 255 feet high It appears that approximately one third of the station will replace three existing generating stations, and to this extent only has authorisation to proceed been given at present The displaced stations are antiquated, and it has been calculated that the completion of this part of the scheme will reduce the present output of sulphurous acid by about 30 per cent We understand that the matter is being carefully considered by the Ministry of Health Unless the Ministry, the Government Chemist and the Department of Scientific and Industrial Research, say that no danger accrues from this cause, the full scheme is not to be completed Special methods are being tried for cleaning coal so as to reduce its sulphur content Washing the chimney gases with forced sprays of water is also being tried For large scale research, one of the large London power stations might be employed Lord Birkenhead pointed out that little had been done in the past to develop the cheap supply of electric power, on which our future commercial prosperity largely depends He said that the arguments brought forward by the opponents of the scheme should have been brought forward two years ago, and that the erection of the new power station would, from the commercial point of view, be a great boon to the residents in Battersea In our opinion, intensive scientific study should be devoted to the elimination of sulphurous acid from the chimney gases, and electrical engineers would do well to enlist the aid of chemical experts

Sir Harold Hartley, who delivered the Theodore William Richards memorial lecture before the Chemical Society on April 25, gave an intimate and inspiring account of the social and scientific life of that great Harvard chemist, former president of the American Chemical Society, Davy and Faraday medallist, and Nobel prizeman, who died on April 2, 1928 He said that in Richards chemistry has lost a great experimenter the founder of a famous school of research, and one whose methods and example have exerted a profound influence on chemical investigations in every country His earliest investigation, suggested by Prof Josiah Parsons Cooke of Harvard, under whom he commenced his research career at eighteen years of age, consisted of a re determination of the atomic ratio hydrogen oxygen, and involved the weighing of globes of hydrogen, the passage of the gas over cupric oxide, and the weighing of the resulting water The excellence of the work was recognised by the award of a fellowship which enabled Richards to spend a semester at Gottingen, and to visit most of the important laboratories of Germany, Switzerland, France, and England He always advocated this plan of spending half a year abroad in intensive work in one institution, followed by half a year of peripatetic study, as generally offering the greatest advantage in the time available In 1901 he received an unusual compliment in the form of a call to a chair at Gottingen, but his services were retained at Harvard, where he remained for the rest of his life The investigation of atomic weights occupied the greater part of Richards's life, their fundamental nature appealing especially to his intense desire to know something more definite about the material and energetic structure of the universe, his first choice was copper, the study of which occupied several years, and was carried out with his typical thoroughness

Richards was responsible for devising the nephelometer as a means of overcoming certain difficulties in atomic weight work which arise from the slight solubility of the silver halides A second visit to Germany in 1895 gave him a new outlook, and he returned an enthusiastic, if critical, disciple of van 't Hoff and Ostwald All of Richards's early work had been performed under most trying conditions in Boylston Hall, but in 1912 the Wolcott Gibbs memorial laboratory, which in equipment convenience, freedom from fumes and dirt and from rapid temperature changes probably excels any other research laboratory in the world, was erected A constant stream of researches on atomic weights came from Harvard, but the solution of the problem of their relationships seemed no nearer Richards expressed his conviction that the periodic system represents only in a very crude fashion relationships which are highly complex and subtle The answer to the riddle

was, however, provided in 1912 by Russell, Fajans, and Soddy in their conception, independently, of isotopy Richards's interests were not confined to atomic weights, and his activities included investigations on electro chemistry, thermo chemistry, and ionic equilibria Four papers, entitled "The Significance of Changing Atomic Volume published in 1901–4, outlined the fields of physical chemistry with which he was most closely to be associated for the next twenty five years Many compressibilities up to 500 atm were measured from 1904 onwards, and fresh possibilities were opened in 1922 by Bridgman's researches on compressibility up to 12,000 atm during the last year of Richards's life much of his time was devoted to the analysis of Bridgman's results and his own earlier work, and the relative magnitudes of the internal pressures are found to correspond satisfactorily with the physical properties of the elements examined A long series of researches in thermo chemistry originated in his interest in the energy changes and changes in heat capacity accompanying chemical action, and their relation to his theory of compressible atoms He was in fact, the pioneer of modern precision calorimetry, and his electro chemical work is a most valuable contribution to our knowledge of amalgams His work, indeed constitutes a coherent attack on the constants of Nature

THE Annual Report for 1927–28 of the Agricultural Research Council of the Ministry of Agriculture consists of short summaries of the work in progress at the research stations and institutions in Great Britain in receipt of grants It is a lengthy document, full of interest both scientific and practical A perusal of this document would cause no little surprise to those who are loud in their complaints that the Government does little or nothing to benefit the agricultural industry, and would be enlightening to others who do not realise the extent to which research into the sciences associated with agriculture is assisted by government funds Scientific research however, is not always popular even among those who will ultimately benefit from it and unless it can be proved that the results of such work are of immediate service to the farmer he at any rate, is apt to be sceptical of its value Criticism of this kind, however is apt to neglect two important aspects of the problem which become of increasing importance in a country like Great Britain Under the various conditions of soil and climate, transport and markets, the agricultural industry is not really one, but consists of a large number of concerns differing largely in their needs, and in the character of the problems that beset them, so that results of research of vital importance to one section of farmers may be of little or no interest to others As time goes on and an ever greater call is made upon the products of the soil, and farming departs more and more from traditional and accepted methods, which were in the main designed to limit risk, and ensure economic stability, so will the industry depend to an increasing extent upon the results of scientific research It is in these two directions that the contents of this volume are of special interest, dealing as it does with almost all aspects of plants and animals in relation to the soil and to the means of their production

IT is perhaps invidious to single out the work of any single institution from this interesting account, but the Rothamsted work on the inoculation of lucerne, and that at East Malling on the manuring of apple trees, will appeal with great force to those interested in either of those problems In view of the economic pressure in the farming industry and the reversion of arable land to grass, and the attempts that are being made in the direction of intensive grassland production, the work at Cambridge, Aberystwyth, and Aberdeen will make a wide appeal It is now beginning to be realised that the problems connected with the management of a mixed herbage such as natural and artificial grassland are more difficult of solution than those of a single crop The work of these centres has made it clear that, given suitable soil and climate, it is possible to produce in grass all types of food for live stock, from that which is little better than straw to that which is more similar in character and composition to linseed cake It is surely a triumph for scientific work that this should have been possible, and should be a sufficient answer to those, ever decreasing in numbers who doubt the value of expenditure on research

A COMMITTEE has recently been formed, with Lord Cottesloe as chairman with the object of placing a memorial in the Tower of London to the memory of the Rev Alexander John Forsyth, the inventor of the percussion lock and primer for firearms Forsyth was born in 1769 at Belhelvie, Aberdeenshire, and died there on June 11, 1843 A graduate of King's College, Aberdeen, he succeeded his father as minister at Belhelvie He was interested in the scientific discoveries of his time, and was a chemist and a practical mechanic following up experiments made many years before in France, he succeeded in constructing a percussion lock which, with the use of detonating compounds, eventually superseded the old flint lock that had been in use for two hundred years Forsyth's invention was made in 1805, and in 1806 he carried out experiments in the Tower of London It was not until 1834, however, that the percussion lock was adopted for the British army Interest in his work has been renewed by the presentation to the Tower Armouries of examples of early English firearms by Prof Reid, of Aberdeen, one of the few surviving relatives of Forsyth The movement has the support of the Gunmakers Company and the Gunmakers Association, and particulars of the proposal for a memorial can be obtained from the Curator of the Armouries, Tower of London

ON April 24 Mr Dendy Marshall read a paper to the Newcomen Society on The Rainhill Locomotive Trials of 1829" These famous trials actually took place in October 1829, the four competing engines being the 'Rocket,' 'Novelty,' 'Sans Pareil,' and 'Perseverance' At that time the Liverpool and Manchester Railway was nearing completion, but though some fifty locomotives had been constructed

in England and many of these were in daily use at various mines and on the Stockton and Darlington line, the directors of the Liverpool line were still in doubt as to whether to use stationary engines with rope haulage or locomotives It was on the advice of the well known engineers Rastrick and James Walker that a prize of £500 was offered for a locomotive which should be "a decided improvement on those now in use, as respects the consumption of smoke, increased speed, adequate power and moderate weight" Of the four engines entered, only the 'Rocket' fulfilled all the conditions and went through the trials satisfactorily, a performance which did much to establish the locomotive in an unrivalled position as the motive power of the future The design was due to the collaboration of George and Robert Stephenson and Henry Booth, and the engine was the first locomotive containing the present features of a roomy fire box combined with a tubular boiler The 'Rocket' was employed on the Liverpool and Manchester Railway until 1836, when it was sold for £300 It then worked on the Midgeholm Colliery until 1844, and in 1862 was secured by Bennet Woodcroft for the Patent Office Museum, from which it passed to the Science Museum, where it is one of the most attractive of many historic relics of the past Simultaneously with the meeting of the Newcomen Society in Caxton Hall, the American members of the Society held a meeting in New York, at which Mr Dendy Marshall's paper was also read An abridgment of the paper appeared in the *Engineer* for April 26

THE atmosphere of incredulity surrounding the subject of the 'sea serpent' tends to obscure the fact that several varieties of true sea snake are frequently met with in the Indian Ocean and other tropical waters Little, however, is known of their habits, a deficiency which adds interest to a recent report from the steam trawler *Humphrey*, Capt John MacDonald On Dec 22, 1928, while steaming eastward from Torres Strait, a commotion was observed in the water about four miles from Double Island, and on closing it a large fish was seen to be struggling in the coils of a sea snake, which was engaged in rapidly striking the fish's head with its own On the ship's approach, the snake sank slowly with its prey, which it had apparently succeeded in stunning The snake is described as being striped with bright yellow and dull brown, in rings, a coloration which points to its having been a *Platurus fasciatus* Later in the same day, several similar snakes were seen, ranging from three to nine feet in length According to the *Humphrey*, they are not uncommon in these waters, and craft at anchor are accustomed to plug their hawse pipes in order to prevent the snakes, whose bite is reputed to be poisonous, from coming on board by climbing the anchor cables

AT a meeting of the Linnean Society of London on April 18, Sir Sidney Harmer read extracts from correspondence relating to the habits and probable end of "Pelorus Jack," probably a specimen of Risso's dolphin, which for many years accompanied ships through Pelorus Sound, at the northern extremity of South Island, New Zealand "Pelorus Jack" was shot at several times, but after 1904 was protected by successive Orders in Council of the Government of New Zealand The animal used to escort steamers appearing in the Sound for about 5 miles, leaping and gambolling under their bows It is thought that it was killed about April 1912, possibly by a twin-screw steamer which took the place of a single screw vessel formerly plying on a route passing through Pelorus Sound In the discussion which followed, Dr G P Bidder referred to an experience of his own off Plymouth in a 3 ton cutter Five or six porpoises played close alongside, one within reach from the steersman's seat, but none touched the boat Mr H N Ridley stated that off the Dindings, on the coast of the Malayan Peninsula, his launch had been repeatedly escorted by dolphins, which rubbed against the boat and played so close to it that they could be slapped The general opinion was that dolphins do not rub against vessels to clear themselves of barnacles, as has often been suggested Dr Bidder stated that the size and character of the dolphin's brain are such that it is capable of delighting in exhibiting skill and may be attracted to a ship by its noises The classical stories of the friendliness of dolphins towards mankind may not be quite so incredible as we have supposed

THIS year the State of Western Australia celebrates its centenary An article in the *Nineteenth Century* for April by Mr J W Kirwan recounts some of the remarkable developments in that part of Australia during the last hundred years Although known to the Portuguese and Dutch at least from the seventeenth century, no notice was taken of Western Australia until early in the nineteenth century It was only in May 1829 that formal possession was taken by Great Britain of the west coast of New Holland and a settlement was founded on Swan River At the end of that year the new colony contained only 850 settlers The struggle that faced them was severe Knowledge of conditions had to be learnt slowly, and the aborigines were none too friendly After five or six years the colony had made little progress Then the introduction of penal labour improved matters, and most of the new settlers turned into good colonists But it was the gold rush in the eighties and nineties of last century that set the colony on its feet and raised it from poverty and stagnation to prosperity and progress The gold rush brought men of ability and enterprise as well as others of little value Public works were undertaken, the agricultural wealth of the State was realised, and steady and continuous development begun. The population is now above 400,000 and there is ample space for many more

ON April 24 a Fairey monoplane, piloted by Squadron Leader A G Jones Williams and Flight Lieutenant N H Jenkins, left Cranwell Aerodrome, Lincolnshire, with the intention of making a non stop flight to Bangalore, India According to the Karachi correspondent of the *Times*, they passed over that city on the afternoon of April 26, and shortly afterwards returned and descended owing to lack of

petrol They had flown a distance of approximately 4130 miles in 50 hours 48 minutes, Karachi was reached in a little more than 48 hours The mono plane was specially designed for the journey, and was fitted with a Napier Lion engine giving 530 h p at full throttle Its weight when fully loaded was about 16,000 lb, and it is estimated that a further 1000 lb of fuel could have been carried had a suitable runway been available for the start The average speed for the first 2000 miles was 96 miles an hour, but along the Persian Gulf the average dropped to 70 miles an hour, the airmen travelling at a height of about 10,000 feet, being unaware of a favourable wind up to about 6000 feet

Recent additions to the Department of Entomology of the British Museum (Natural History) include a further batch of insects presented by Mr R E Turner, which, with the consignment announced last autumn, makes a total of 13,946 insects of various orders collected by him in South and South west Africa during 1928 Upwards of 6000 of these specimens are Hymenoptera, upon which Mr Turner is a well known authority, while some 4000 are Coleoptera (beetles) But all orders of insects are represented in this donation, which, when fully worked out, will form a most valuable contribution to the knowledge of the insect fauna of the southern extremity of the African continent, especially since many of the specimens were obtained in localities where little if any collecting has hitherto been done Prof V M Goldschmidt, of Oslo, has presented to the Mineral Department of the Museum both rough and faceted specimens of olivine of gem quality recently discovered in western Norway Mr G Tandy, of the Department of Botany, who has recently spent five months with the Great Barrier Reef Expedition, has brought back a large number of specimens illustrating the marine flora of the Reef and adjacent areas, which are being added to the botanical collections

It is announced that the first Congress of the International Society for Microbiology, which was fixed to take place in Paris in October 1929, has been definitely postponed to June 25, 1930 The programme, which has already been published in various scientific journals, will stand

After fifty years in the service of the Royal Institution, Mr Henry Young is about to retire from his post as assistant secretary and keeper of the library He was engaged as an assistant in the library in 1879, when Tyndall was the resident professor, and was promoted ten years later to the position which he now occupies He has been a devoted servant to the Institution and a familiar friend to a large number of the members The Royal Institution is full, as is well known, of interesting and honourable traditions, and Mr Young has been and still is one of the chief agents of their preservation In his place Mr Thomas Martin, at present secretary to the Institute of Physics, has been appointed as general secretary, Mr Ralph Cory, assistant in the library, becomes librarian.

Applications are invited for the following appointments, on or before the dates mentioned:—A first assistant in the Clinical Laboratory of the Manchester Royal Infirmary—The General Superintendent and Secretary, Royal Infirmary, Manchester (May 8) A public analyst for the City of Salford—The Medical Officer of Health, 143 Regent Road, Salford (May 11). A ballistic research officer under the Ordnance Committee—The Secretary, Ordnance Committee, Royal Arsenal, Woolwich, S E 18 (May 11) A lecturer in pharmacy at the Belfast Municipal College of Technology—The Principal, Municipal College of Technology, Belfast (May 14) An assistant morbid anatomist and curator of the museum of the Royal Free Hospital and London School of Medicine for Women—The Secretary, Royal Free Hospital, Gray's Inn Road, W C 1, or The Warden and Secretary, London (R F H) School of Medicine for Women, Hunter Street, W C 1 (May 15) A lecturer in biology at the Portsmouth Municipal College—The Secretary, Offices for Higher Education, Municipal College, Portsmouth (May 25) A technical officer and a junior technical officer at the Royal Aircraft Establishment, for work relating to the development of instruments and allied equipment for aircraft use—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (May 25) An assistant lecturer in physics in the University of Manchester—The Registrar, The University, Manchester (May 25) An assistant lecturer in zoology in the University of Bristol—The Secretary, The University, Bristol (June 1) An assistant lecturer in economics at the University College of North Wales, Bangor—The Registrar, University College of North Wales, Bangor (June 8) An assistant in natural history at University College, Galway—The Secretary, University College, Galway (June 8) An assistant in the Mechanical Engineering Section of the Engineering Department of the Halifax Municipal Technical College—The Principal, Municipal Technical College, Halifax A master for building subjects in the Southall Junior Technical School—The Principal, Junior Technical School, Southall, Middlesex A resident lecturer in science, biology and botany, elementary chemistry and physics, at St Gabriel's Training College for Women—The Principal, St Gabriel's Training College for Women, Camberwell A lecturer on physics and chemistry at the Maria Grey Training College—The Principal, Maria Grey Training College, Salusbury Road, N W 6 A technical assistant in the Department of Entomology of the Museum of Zoology, Cambridge—C Forster Cooper, Superintendent, The Museum of Zoology, Cambridge An experienced shorthand typist secretary for library work, indexing and correspondence, at the Research Station, East Malling—The Imperial Bureau of Fruit Production, Research Station, East Malling, Kent

Erratum—In the article on "High Voltage Alternators for the Grid" in Nature of April 13, p 586, "25 kilowatts" on line 33, and "10 kilowatts" on line 34, of the second column, should read "25,000 kilowatts" and "10,000 kilowatts" respectively

Research Items

A REMARKABLE OBJECT FROM BENEATH THE RED CRAG.—In *Man* for April, Mr. J. Reid Moir describes a remarkable object obtained from beneath the Red Crag at a pit on the north bank of the River Gipping at Bramford, near Ipswich. It was obtained from the detritus bed lying below loamy sand, which in turn was below glacial gravel. The bed lies at about 100 O.D. upon the surface of the London Clay. It is made up of typical sub-crag detrital material and does not exhibit any signs of glacial disturbance. The object was discovered in 1926, but beyond being labelled was not specially noted until attention was directed to its remarkable character by the Abbé Breuil, who, on examining it, pronounced it shaped by the hand of man. In shape it is like an elongated egg with one end slightly blunter than the other. At each end is a small depression or punctuation, and similar marks are visible on other parts—in places four or five being grouped together as a rhomboid or as straight lines. It is possible that these may be due to decomposition of crystalline grains. The whole surface has been scraped with a flint, so that it is covered with a series of facets running fairly regularly from end to end. From each one is made up a number of longitudinal striations of unequal depth; a number of fine concentric incisions are visible at one of the poles. The specimen is of a greyish-brown colour, weighs approximately ½ ounce, and measures at its greatest length $1\frac{7}{16}$ in., and at its greatest depth $\frac{13}{16}$ in. The exact nature of its material is in doubt. The Abbé Breuil compares it with the steatite sling stones of New Caledonia.

TLINGIT EMBLEMS.—In the *Museum Journal* (Philadelphia) for December last, Mr. Louis Shotridge describes a number of ancient clan emblems of the Tlingit of Alaska: these formed part of a collection of ancient objects representative of the traditional art of this people which he was able to collect solely in virtue of the fact that he himself was a Tlingit of noble birth. These objects, it is stated, had not seen the light since the introduction of the white man's religion and law. The emblems are in the form of ceremonial head-dresses, each of a once generally recognised grade in rank and importance. The Tlingit were divided into two nations, each of which was subdivided into clans. Each clan had its ceremonial head-dress, but its possession was often the subject of dispute and the cause of internecine war. On the side of the Tlingit naedi nation, first in importance was the raven hat, which signified culture; next in order the whale hat, an emblem of greatness and the cult object of the greatest clan. The frog hat signified persistence and was the emblem of the Kiks adi clan. On the side of the Shungookaedi nation were the eagle, the grizzly bear, the emblem of power, and the wolf, signifying courage. The hats are for the most part woven of roots of the spruce, with highly conventionalised representations of the head or other part of the animal simulated carved in wood and ornamented with locks of human hair. On most there was a 'top stock' of spruce roots, woven to resemble a number of interlocking cylindrical boxes superimposed which could be made to expand or contract. The number of these boxes or divisions represents the number of ceremonies in which each hat was used.

LESSONS FROM THE HUMAN FOOT.—In the third lecture in memory of Hugh Owen Thomas, delivered before the Medical Institution at Liverpool on May 11, 1928, Sir Arthur Keith discussed some of the problems of the human foot (*Jour. Bone and Joint Surgery,* January 1929). He looked upon the sequence of postural functions as a more promising line of investigation than anatomical details, and took it as proved that the human foot had been evolved from a prehensile foot, the nearest representative of the primitive form being that of the chimpanzee. The chief changes which transformed the prehensile into plantigrade were due to growth—a recession of growth of the external or planar limb of the prehensile foot with a progressive growth in the hallucial limb. Three stages of this growth development can be followed: the pronograde prehensile foot, the small orthograde foot (hylobatian), the massive orthograde foot (troglodytian) leading to the human plantigrade. The mass of the body has been the most important factor in bringing about the later changes, and it is inferred that it was the weight of the body which compelled man's anthropoid ancestors to assume terrestrial habits of life, and that man is the descendant not of a pigmy anthropoid but of one of massive body.

RURAL POPULATION OF NEW YORK STATE.—In a study of the movements of population in New York State from 1855 to 1925 (Cornell University Agricultural Experiment Station *Memoir* 116) Mr. B. L. Melvin brings to light a number of interesting facts especially with regard to recent years. While the population of New York State increased 7.5 per cent from 1920 to 1925, the total city population, including New York City, grew less than did other classes, and the larger cities gained less than the smaller ones. Suburbanisation was the most marked phenomenon in the shifting of population in that period. As a result, rural population increased, especially in those counties where urban influences were most dominant. That this increase was due to urban influences, provided no doubt by improved transport, seems to be clear from the fact that farm population increased only in suburban counties but decreased in all others. Cities seem to maintain the farm population near them rather than to cause its decline. In such a study, of course, the use of terms is somewhat arbitrary. Mr. Melvin classes as rural population all persons living outside places of population 2500 and above. The pamphlet is well illustrated with distributional maps.

MIGRATIONS OF THE ARCTIC TERN.—A *Daily Science News Bulletin*, issued by Science Service, Washington, D.C., announces that an Arctic tern ringed as a fledgling at Turnevik Bay, Labrador, on July 28, 1928, was found dead on the beach at Margate, fifteen miles south-west of Port Shepstone, Natal, South Africa, on Nov. 14, 1928. This is a remarkable record, not only for the distance covered, but also for the fact that the bird could have been only about three months old at the time of the flight. It suggests the possibility that the birds, which are rarely or never seen on the south Atlantic coast of the United States, may cross the ocean to Europe and then proceed south. The extensive migrations of the Arctic tern are well known, and owing to its habit of breeding in the northern portion of the northern hemisphere and of wintering in the far south, it enjoys more hours of sunlight than any other living creature. In the northern part of its breeding range and during its stay in the Antarctic regions, it lives practically in continuous daylight.

GENITALIA AND GENITAL DUCTS OF INSECTS.—C. J. George (*Quart. Jour. Micr. Sci.*, vol. 72, part 3) has examined the development and morphology of

the genitalia of Homoptera, as represented by the frog hopper, *Philænus*, and of Zygoptera as represented by *Agrion* (one of the demoiselle flies) and sets down the homologies of the parts As the result of studies on the development of the genital ducts, he concludes that the vaginal opening in Orthoptera, Hymenoptera, Homoptera, Diptera, and Lepidoptera is homologous, and that the vaginal opening in Coleoptera is homologous with the oviducal opening of Lepidoptera and with the opening of the accessory gland of Homoptera, Hymenoptera, Diptera, and Isoptera The common oviduct, being formed differently in the different groups, is not homologous, and the accessory organs, for example, spermatheca, are not homologous The author discusses the probable lines of evolution of the female ducts in Insecta, and points out that the Ephemeroptera with their double female openings on the seventh abdominal segment exhibit an ancient condition, and that many higher insects pass through this condition during their larval and nymphal stages The existence of an ectodermal invagination behind the seventh abdominal segment in Homoptera and Orthoptera shows that the acquisition of a single gonopore was the next step The later ontogenetic history shows that there has been a tendency to shift the gonopore to the terminal abdominal segments The conclusion is that the Orthoptera, Homoptera, Lepidoptera, and Diptera are closely allied, but the Coleoptera have had a different line of evolution

CHROMOSOME LINKAGE IN *ŒNOTHERA* HYBRIDS —Prof R R Gates and F M L Sheffield, in *Phil Trans Royal Soc*, B, vol 217, 367 (1929), have published an account of important cytological researches on reciprocal hybrids obtained from *Œnothera ammophila* and *Œ* (*biennis* × *rubricalyx*) The reciprocal F_1 hybrids are very different and are patroclinous The chromosome linkages were found to be unlike in the reciprocal hybrids In *Œ ammophila* × (*biennis* × *rubricalyx*) the spireme segments in diakinesis into three free pairs of chromosomes and a ring of eight In the reciprocal cross there are, on the contrary, seven chromosome ring pairs That the latter has all its chromosomes paired makes it clear that complete pairing is not necessarily a sign of the homozygous condition The conclusion is reached that since the same two haploid sets of chromosomes are present in the reciprocal hybrids, the cytoplasm plays a part in determining what pairing shall take place, it influences the attractions between the chromosomes and the distribution of chromosomes in the reduction division This leads in itself to a departure from usual Mendelian behaviour The production in F_1 of true breeding hybrid types is to be explained through the occurrence of chromosome linkage, which prevents free assortment of the chromosome pairs, and hence of the differential characters Linkage differences in *Œnothera* occur in wild species as in mutations arising in controlled experiments It seems, therefore, that evolution can occur through germinal changes (mutations) of various kinds arising in a succession of species which are of natural hybrid origin, but, in the main, breed true because of their persistent chromosome linkages in meiosis In this probable sequence we have suggested a new evolutionary phenomenon which may be of much significance for the student of the origin of species

A NEW 'DEEP' IN THE PACIFIC —A *Daily Science News Bulletin*, issued by Science Service, Washington, D C, announces that the non magnetic ship *Carnegie*, now cruising in the Pacific Ocean, has discovered a new deep some fifty miles west of Tahiti The greatest depth was 5400 metres, and its area does not seem to be extensive The observations were made with the sonic depth finder Captain Ault named the depression the Bauer deep, after the director of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington A further discovery was that of a submarine ridge in approximately lat 23° S and long 80° W This seems to be a northward extension of the ridge on which the San Felix Islands lie It was named the Merriam ridge Other oceanographical discoveries were made, but details are not yet given

ICE IN THE ARCTIC SEA —The Danish Meteorological Institute has published in the *Nautisk Meteorologisk Aarbog*, 1928, its usual report on the state of the ice in Arctic Seas during the year Most of the observations are naturally for the summer months, but off south west Greenland, western Spitsbergen, and in the North Atlantic it is possible to give reports for all months In the Barents and Kara Seas there was less ice than usual in the summer Franz Josef Land could be reached in August, while in September there was even water between some of the islands of the archipelago In Spitsbergen waters conditions were favourable except for unusually late streams of pack ice on the south west coast In August and September Spitsbergen could be circumnavigated without difficulty The east coast of Greenland had rather more ice than usual, and this state of affairs was found also in the east of Spitsbergen On the other hand, there seems to be no evidence of an increased outflow of pack ice by the other outlets of the Arctic Sea Davis Strait and Baffin Bay had rather less ice than usual Reports from the Bering Sea are few and vague Iceland coasts were practically free throughout the year On the Newfoundland Banks pack ice was below the normal in every month, but icebergs were much above the normal in April, May, and June The report is illustrated with the usual charts for the spring and summer months

RAMAN EFFECT AND THE SPECTRUM OF HYDROGEN —In NATURE, Jan 26, p 127, Prof H S Allen suggested the view that many of the faint lines in the secondary spectrum of hydrogen may result from the bombardment of hydrogen molecules by light quanta of frequencies corresponding to the Balmer lines A table was given for the first five Balmer lines showing a number of possible Raman lines having frequency differences with respect to the exciting line which were integral multiples of a particular wave number Dr D B Deodhar, Physics Department, University of Lucknow, in a letter to the Editor, states that he has made a further search in this direction, using the recently published wave length tables of Finkelnburg, and for ten members of the Balmer series has found a large number of lines, both of lower as well as of higher frequencies, which approximately occupy the positions of Raman lines Finkelnburg's experimental tube was energised with 2000 volts, giving a discharge current of 600 ma, while the current in Gale, Monk, and Lee's tube was only 20 ma Finkelnburg discovered about 2000 lines which were previously unknown in the spectrum of hydrogen The intensity of the Balmer lines in his experiments was considerably greater than in those of Gale, Monk, and Lee It is interesting to note that a majority of the Raman lines of *increased* frequency belong to the newly discovered lines, and that they are of very low intensity Dr Deodhar expresses the opinion that his results strongly corroborate the view put forward by Prof Allen, but, in consideration of the high accuracy of recent measurements of wave lengths in the hydrogen spectrum, it may be well to scrutinise such results very carefully

MOLECULAR RAYS —Some experiments performed with beams of molecules by Prof O Stern and F Knauer (*Zeitschrift für Physik*, Mar 7) furnish good qualitative evidence that particles of atomic dimensions, as well as electrons, behave as waves in certain circumstances The de Broglie waves of a hydrogen molecule at room temperatures gave an average wave length of about 1 A, and should therefore be reflected specularly from a well polished mirror if they are incident upon it at an angle of the order of a thousandth of a radian, as are X rays of corresponding wave length This has been shown to be the case, the efficiency of reflection is greater the less the glancing angle, and the angle at which reflection first becomes marked is about that which would be expected from the size of the irregularities on the polished surface, whilst the amount of reflection increases as the temperature of the beam of molecular rays is lowered, that is, as the equivalent wave length of the particles is increased Prof Stern was unable to obtain any positive results in an attempt to diffract molecules from a ruled grating, but his results with a crystal surface, although not quite definite, are compatible with the idea that diffraction takes place in this case

LOAD AND TARIFF IN ELECTRIC SUPPLY —The standard method of distributing electrical energy in Great Britain is by means of three wires carrying alternating currents, the phases of the currents in each wire being different The consumer's load can either be connected in mesh (like a triangle) or in star (the three wires being joined together at one point) When the load is balanced, the measurement of the power taken presents no difficulty When, however, the power expended in each of the three arms is different, the problem becomes complex and the ordinary methods of measurement give no useful or sufficient indication of the nature of the load taken by a consumer In addition to the values of the three currents in the arms, we have to take into account the phase differences between these currents and the electromotive forces driving them This problem, which is almost purely mathematical, was discussed in a paper by E W Hill, read to the Institution of Electrical Engineers on April 5 The solution arrived at, however, whilst possibly better than some of the methods at present in use, appears to us not to classify consumer's loads in a truly equitable way If the assumption is made that all the waves follow the harmonic law, the solution given by Russell, which is referred to in the paper, seems to be a satisfactory one The general case, however, yet remains to be solved, although a very large number of papers have been written on the subject, especially in America There are few industrial applications where mathematics can be more usefully employed than in electrical engineering

GEOGRAPHICAL INFLUENCES AND RADIO WAVES —In the *Revue Scientifique* for Mar 23, R Bureau, of the French meteorological office, gives data which show that ordinary meteorological and geographical causes exert a very appreciable influence on the propagation of radio waves In the early days the hypothesis of a conducting layer in the upper atmosphere was a great help in enabling us to picture how part of the radio energy flowed round the earth With waves the frequency of which exceeds 6000 kilocycles (wave length less than 50 metres) it gives a fairly satisfactory explanation of the 'zones of silence' observed in practice It is now accepted, however, that the height of this layer is a quantity varying at different times of the day and that there are possibly several conducting layers at different heights Apart, however, from what happens in the upper atmosphere, important effects are produced in the troposphere, which is about six miles in height, and in the lower layers of the stratosphere Contrary to expectation, direct experiment has shown that the surface which separates the stratosphere from the troposphere has little, if any, effect on the propagation of the waves It is found that short waves, whether entering or leaving France, have very different properties, which depend on their direction of propagation Waves coming from the Caribbean Sea, Panama, and the Gulf of Mexico suffer little attenuation On the other hand it is, if not impossible, at least very difficult to get signals from the north east of the United States and from Newfoundland Signals given by a 200 watt emitter on the Atlantic coast of Morocco seem never to reach central or eastern Europe, although they can be heard in other directions for thousands of miles The radio waves seem to have difficulty in passing through the surface of separation between a mass of cold air and a mass of warm air The lines which separate the audible zones from the zones of silence often coincide very closely with the meteorological lines separating masses of cold and warm air

CRYSTAL STRUCTURE OF β THALLIUM —At the ordinary temperatures, α thallium has a hexagonal close packed lattice Drs Nishikawa and Asahara have shown by X ray methods that it has an inversion point at about 230° C The change in crystal form consequent upon this has been investigated by Mr Sinkiti Sekito, of the Research Institute for Iron, Steel, and other Metals, Sendai, Japan, who has sent us a short communication on the subject The metal was retained in the form stable above the inversion temperature by quenching it in iced water Photograms were then prepared, using a chromium anticathode and taking the wave length as $CrK_{\alpha} = 2\ 287$, $CrK_{\beta} = 2\ 080$ It appears from these that β thallium has a face centred cubic lattice ($a = 4\ 841$) Calculating the specific gravity from this value, the figure 11 86 is obtained, which agrees well with the results obtained by other methods A similar face centred cubic structure was obtained with thallium alloys containing bismuth, lead, antimony, or tin in solid solution Mr Sekito concludes, therefore, that the face centredness of thallium above 230° C has been definitely established

HYDRATES OF CADMIUM SULPHATE —The hydration of cadmium sulphate was for long the subject of controversy, until Hauer and also Rammelsberg showed that, at ordinary temperatures and pressures, this salt crystallises from its solutions as the monoclinic hydrate, $CdSO_4$, 2 67 H_2O This result was confirmed by later investigators and, as a consequence of vapour pressure measurements by Carpenter and Jette in 1923, the temperature of transformation into the monohydrate was given as 41 5° A systematic study of the dehydration of this salt, carried out by Prof Luca Coniglio, is recorded in the *Rendiconti* of the Academy of Physical and Mathematical Sciences of Naples for January–April 1928 The experimental data show that at 74°, $CdSO_4$, $\frac{8}{3}H_2O$ loses $\frac{5}{3}H_2O$, giving the monohydrate, which is stable until the temperature reaches about 120°, when further expulsion of water occurs, with formation of $3CdSO_4$, $2H_2O$ The latter hydrate is stable at temperatures below about 138°, when another molecule of water is lost, giving $3CdSO_4$, H_2O, which is converted, but only comparatively slowly, into the anhydrous salt at 150° It seems probable that the water of crystallisation of the original salt is combined, not with a single molecule, but with three molecules, of the cadmium sulphate, the formula being $3CdSO_4$, $8H_2O$

Developments of British Chemical Manufactures

AT the instance of the British Science Guild, a public meeting was held at the Mansion House, London, on April 24, when an account was given of certain phases in the development of British chemical industry Lord Melchett, who presided referred briefly to the origin and the present status of the nitrogen industry, remarking that although the synthetic ammonia industry has grown up in the last few years, the problem of the supply of artificial fertilisers is by no means new Nevertheless, older sources of combined nitrogen were inadequate, and had the new industry not been created the fields of the world would soon have starved for one of the most elemental necessities The new textile also, originally a British conception, has proved applicable in numerous directions, whilst the drug industry is proceeding in the direction of the synthesis of highly complex substances Other manufactures are equally dependent on the prosecution of scientific research, and the value of such research should be more fully realised

Sir Frederick Keeble then addressed the meeting on "Fertilisers from the Air," saying that, like the legendary discovery by Prometheus of fire, fertilisers have been brought down from heaven by modern chemists Without sufficient nitrogen in the form of salts of ammonia or nitrates, the green plant is unable to manufacture sugars and proteins at its maximum capacity lack of available nitrogen has always limited life on this planet Natural processes are too slow for the modern world, and before the year 1913 a general nitrogen hunger had become apparent Now, however, the nitrogen of the air is being made into fertilisers at the rate of more than one million tons a year, drawing on a supply so vast that, at the present rate of use, it will last for four thousand million years Farmers are now acquiring the habit of using larger quantities of nitrogenous and other fertilisers, Holland leads the way, followed by Belgium, Germany, Japan, Egypt, Great Britain, and France, whilst the use of nitrogenous fertilisers in the United States of America is well below that of Western European countries The material is now one of our cheapest commodities, and thus provides the farmer with the best means of reducing costs and of obtaining improved economic results from his farm Sir Frederick then outlined the origin and development of the great factory at Billingham, where attention is now being directed to the manufacture of fertilisers containing other plant foods in addition to nitrogen

The 'rayon' (artificial silk) industry was described by Mr A B Shearer, who insisted that the use of the expression 'artificial silk' only keeps alive an erroneous impression of inferiority, since the new textile is no more artificial than is steel or many other manufactured products, and since it possesses none of the chemical, and few of the physical, characteristics of silk The four principal processes involved, in order of their industrial development are those known as the nitrocellulose, cuprammonium, viscose, and cellulose acetate processes Nitrocellulose was first used in 1883 to produce a continuous cellulose thread by Sir Joseph Swan, who in 1885 exhibited fabrics made from his yarns, whilst a year later Count Hilaire de Chardonnet became the first producer of rayon for textile purposes After briefly indicating the nature of the processes employed in the production of these textile fibres, Mr Shearer emphasised the debt which the new industry owes to scientific discovery, and showed how the new fabrics successfully minister to the needs created by changes in the habits and outlook of civilised peoples The difficulties of establishing a new industry are seldom realised, but it must be placed to the credit of British organisation, business foresight, engineering skill, textile technology, and salesmanship, that Great Britain has been able to take and maintain the lead in this great industry Moreover, the use of rayon has had a marked effect on the general condition of the textile industries, its special requirements leading to generally applicable improved methods of manufacture and treatment, in the application of which the worker has benefited

Mr F H Carr spoke of developments in the study and manufacture, particularly in Great Britain, of synthetic drugs The great success of salvarsan provided a strong incentive for the search for other synthetic drugs which exert an antagonistic effect on disease organisms without injuring the infected person, for example, various organic compounds of arsenic and antimony are now employed, especially in the treatment of certain tropical diseases In its normal chemical processes the body is continually producing active principles, chemical substances, which control and regulate its action A study of these substances has led to the possibility of their replacement, in cases of deficiency, by synthetic, or at least externally prepared, substances Insulin has not yet been made synthetically, but adrenaline, secreted by the suprarenal gland, has been synthesised, and, moreover, nearly related compounds with other valuable medicinal properties have been prepared Mr Carr also referred to the synthesis of ephedrine, an alkaloid which occurs in the Chinese plant Ma huang, this substance powerfully relieves the distressing effects of asthma Vitamin D is now made by the action of ultra violet light on ergosterol, a substance derived from yeast

Mr Carr sketched the progress of the medicinal chemical industry in Great Britain, and remarked that to day there are important manufacturing firms which, between them, are making most of the synthetic drugs The fact that there are some exceptions, chiefly substances derived from intermediates employed in the manufacture of dyes, shows that the organisation of chemical industry in Great Britain, although it has made rapid strides, has not yet been completed The changes which have occurred in chemical industry of late years are in large measure the result of the mutual approach and understanding which have already taken place between the business, the scientific, and the practical men in the industry Future progress lies in extending the use of science in the industry, in the first place by promoting research in industrial laboratories in the closest possible relationship with that carried out in academic institutions and under the ægis of the Medical Research Council, and, secondly, by finding employment for greater numbers of scientifically trained staffs and workers to whom is given responsibility and a living interest in the work they are performing

Sir Richard Gregory, who proposed a vote of thanks to the chairman, said that the fact that scientific research leads not only to new outlets for employment but also to the creation of entirely new industries is too often overlooked by politicians British scientific capacity is at least as great as that of any other people in the world, and he hoped that it would be yet more fully employed in such development and creation

Radium Requirements of Great Britain

ON July 7, 1928, the chairman of the Committee of Civil Research appointed a sub committee, with the Right Hon Lord Rayleigh as chairman, to examine the radium requirements of Great Britain in relation to the present sources of supply and to submit recommendations The Report of the Radium Sub Committee (dated Mar 7, 1929) has now been published (London H M Stationery Office 6d) The document is of absorbing interest, for it not only discusses the importance of radium in medical treatment and the amount required for such purposes in Great Britain, but it also presents a valuable survey of the sources of radium production, with special reference to deposits in the British Empire Among the conclusions reached are the following

The amount of radium belonging to the Government which is available for medical purposes in England, Scotland, and Wales is 2 2 grams, and the estimated amount believed to be the property of hospitals and private medical practitioners, or likely to be so in (say) three months' time, is approximately 22 7 grams, making a total of 24 9 (or say 25) grams

The amount required to meet existing needs in Great Britain is probably approximately 49 or 50 grams, that is, an immediate addition of about 24 grams to the existing national stock is required

Owing to the lack of trained personnel and to the inadequacy of the available hospital accommodation it is probable that not more than 20 additional grams of radium could be effectively absorbed for medical purposes by the end of 1930

There exists a pressing need for the establishment of a central stock of radium and the organisation of some systematic method for its distribution

Until sources of supply at present unproved or unknown are discovered in the Empire or elsewhere, the only source from which additional supplies of radium for medical purposes are obtainable in any quantity is the Belgian Congo

The following are the chief recommendations submitted

Steps should be taken at once to ensure the acquisition by instalments of 20 additional grams of radium element for medical purposes

A body of trustees should be appointed entitled the National Radium Trustees, whose duty it should be to hold the funds provided by Parliament or otherwise, and to purchase therewith and hold radium for use by the Radium Commission referred to below

The National Radium Trustees should appoint a body to be called "The Radium Commission," who should have the following powers and duties

Generally to deal with the custody, distribution, and use of all radium held by the trustees, having regard to the advancement of knowledge, the treatment of the sick, and economy of use , and, in particular to consider and approve plans submitted to them for the use of radium for the purposes of medical treatment and research and to make the necessary arrangements for the supply of radium for such uses

As was announced in our issue of April 27, p 649, the Government has accepted the financial recommendation of the Sub Committee, and will contribute £1 for every £1 of private subscription up to £100,000 for the purchase of radium This leaves a sum of £150,000 to be raised by private subscription if the quantity of radium required is to be purchased A double appeal has now been issued An anonymous donor has given £100,000 to King Edward's Hospital Fund for London to form the nucleus of a thank offering fund for the recovery of His Majesty the King, and the *Times* has undertaken to raise the £150,000 required for the National Radium Fund The two movements are in close co operation and have the same treasurer and office organisation The King has signified his approval of the scheme by sending a cheque for £1000, to be divided equally between the two appeals, and other members of the Royal family have contributed The eagerness of the public to express its thankfulness for the King's restoration to health has been marked by its swift response to the appeals, nearly £60,000 being subscribed to the National Radium Fund on the day it was opened Further subscriptions, for either fund, should be addressed The Treasurer, Thank offering Fund, 103 Kingsway, W C 2

Annual Meeting of the International Council for the Exploration of the Sea

THE annual meeting of the International Council for the Exploration of the Sea was held in London on April 8–15 The meetings of the area and other committees took place at the House of Lords, and the rooms of the Zoological Society were placed at the disposal of the Council for the scientific meetings held on April 12 and 13 About sixty delegates and experts attended the meetings

The main work of the Council is organised on a regional basis, and the investigations carried out in each geographical area are reviewed by the area committees, which also lay down the programmes for the ensuing year Hydrography, plankton, statistics, and the study of salmon and trout are dealt with by special non area committees

At the Hydrographical Committee, the main points under discussion were the preparation of mean surface salinity charts for the North Sea, plans for combined work on submarine waves in the Kattegat, and the hydrography of the Faroe Shetland Channel , regular observations of the surface waters on two additional lines in the North Sea were arranged Prof W Mielck presented a report to the Plankton Committee on the work he has carried out in testing the comparative catching power of various types of plankton nets, and Prof H H Gran initiated a discussion on quantitative methods used in the investigation of phytoplankton In the Atlantic Slope Committee under the chairmanship of Dr E D le Danois, Prof A Ramalho gave an account of the Portuguese hydrographical work in the area, including the Straits of Gibraltar and the adjacent Portuguese, Spanish, and Moroccan coasts, and Dr Fernando de Buen demonstrated an inverse correlation between the catches of sardines and sprats, as shown by both English and Portuguese statistics Dr R S Clark gave a detailed account to the Northern North Sea Committee, of the distribution of the young herrings of the northern waters of Great Britain, and Dr A Molander contributed notes on the witch fishery of the area Dr A Bowman, the chairman, read a paper on the age determination of the lemon sole by means of scales In the meetings of the Southern North Sea and Combined North Sea Committees the advisability of continuing the practice of issuing advance proofs of the tables from the *Bulletin Hydro*

graphique to people concerned, was discussed It was decided that this procedure was very helpful and should continue

Prof A C Hardy showed a new model of his continuous plankton recorder, which it is hoped will be of great service in enabling plankton collections to be made from commercial vessels A question which is becoming of great practical importance, namely, the design of fishing gear which will avoid the wasteful destruction of small fish, was discussed by a special Committee on Savings Gear, in the light of experiments carried out in several countries during the past year

Special interest attaches to the recommendations of the Whaling Committee, in view of the recent great expansion of the industry, especially in the Antarctic The Committee expressed the view that, while investigations are not sufficiently advanced to enable definitive and adequate regulations to be framed for the conservation of the stock of whales, there are certain practical steps, for example for the protection of young and immature whales, which might be taken at once by international agreement, and it asked the Council to impress this point of view upon the governments concerned It proposed also the organisation of adequate statistics of the catch of whales in all parts of the world

At last year's meeting the innovation was made of devoting two days to the discussion of subjects of general scientific interest affecting the Council's work, and the same useful plan was adopted at the present meeting The subjects chosen for discussion on this occasion were "Fluctuations in the Age Classes of Fishes," and "Current Measurements, Direct and Indirect" No fewer than twenty communications were read on the former subject, and as there was no time for discussion it was arranged that the papers should be published and debated at the next meeting of the Council The same procedure was adopted for the papers read on current measurements

On Tuesday and Wednesday, April 16 and 17, a joint meeting of the International Council and the Challenger Society was held at the Laboratory of the Marine Biological Association at Plymouth Scientific exhibits were arranged by the staff of the Laboratory on the Tuesday, and on the following morning a discussion took place on the subjects considered at the special scientific meetings of last year, namely, "The Estimation of Phosphates and Nitrogenous Compounds in Sea Water" and "Racial Investigations of Fish" (see *Rapports et Procès Verbaux*, vols 53 and 54, 1929) Prof H H Gran described the results of his work on diatom frequency in relation to phosphates and nitrates He finds that while these salts decrease in proportion with increased frequency of diatoms, there are indications of some other unknown factor also at work Dr W R G Atkins remarked on the necessity for observing the greatest caution in estimating phosphates, as the slightest trace of impurities renders the samples useless

The discussion on races in fish was then opened by Prof E Ehrenbaum In the discussion which followed, the majority of the speakers inclined to the view that the counting of variable characters such as vertebræ, etc, is more likely to show up the effect of local conditions than to demonstrate the existence of distinct races Prof J Hjort proposed that the meeting should send a message to Prof F Heincke as a mark of respect for the great work he originated, many years ago, on the races of herring

Meteorology in India

We have received the first three volumes of a new series of meteorological publications that is being issued by the India Meteorological Department, entitled "Scientific Notes" We suppose that this publication will correspond with the "Professional Notes" of the Meteorological Office, London and if this be the case it will be valuable in that it will place on permanent record contributions to meteorology which, though not always of the first rank in importance, afford collectively a useful body of information, the reliability of which is to some extent vouched for by the issuing authority—in the case of the series under review, presumably the Director General of Observatories in India The only serious drawback of publications of this kind, as compared with similar papers read before a scientific society, appears to be that no discussion of the validity of the conclusions is published with them and the general reader can form little idea, in those cases where novel views are brought forward, as to whether or no a definite advance has been made

The first 'note' is by Mohammad Ishaque It is entitled "A Comparison of Upper and Gradient Winds at Agra and Bangalore" Here no novel opinions are put forward, but an unfortunate mistake in the statement of the motion of winds under balanced forces has been made in the introduction —a mistake that would immediately have been pointed out had the paper been read before a scientific audience—namely, that the ordinary 'gradient wind' equation does not hold at the equator, and therefore that the fairly good agreement found in temperate latitudes between the gradient wind and the actual wind at a height of 500 metres can scarcely be expected to hold in such a low latitude as that of Agra (27° N) or at Bangalore (13° N) This is no mere verbal slip, the author did not mean 'geostrophic' wind instead of 'gradient' wind, for he states that in determining his theoretical 'balanced' wind the curvature of the isobars was taken into account

Mr Ishaque's results show an astonishingly poor agreement between the computed and observed winds at Agra the correlation coefficient is only 0 34 for a height of 500 metres, and 0 39 for 1000 metres Sir Napier Shaw in his "Manual of Meteorology" quotes coefficients of about 0 7 and 0 8 for observations made in England To an uncritical reader, noting these contradictory results and observing that the Indian meteorologist was careful to deal only with days on which the pressure gradient was apparently determinable, an important fact would appear to have been established, but when it is pointed out that in England, where the difficulties in the way of obtaining a close network of reliable observations of barometric pressure must be less than in India, determination of the pressure gradient, and from it the 'gradient wind,' is impossible to do accurately, one is tempted to wonder whether the relative magnitude of the correlation coefficients in the two countries are not a measure simply of the point to which accuracy of measurement of barometric pressure has been carried in each case

The second and third 'notes' are useful contributions of a straightforward kind, dealing respectively with the hourly rainfall of Madras over a long series of years and with an interesting type of thunderstorm—the 'nor'wester' of South Bengal The nor'wester appears to be a thunderstorm of the line squall type which yields hailstones of a size fortunately seldom encountered in Europe, but the maximum wind speeds are more comparable with those of the European line squall and rarely exceed 50 miles an hour The storms are most frequent in April and May

University and Educational Intelligence

CAMBRIDGE —The Adams Prize for 1927–28 has been awarded to Prof Sydney Chapman, professor of mathematics in the Imperial College of Science and Technology, London The value of the prize is about £246 The subject set was "The Variations in the Earth's Magnetic Field in Relation to Electric Phenomena in the Upper Atmosphere and on the Earth"

DR R P RAUP, professor of the philosophy of education in Teachers College, Columbia University, New York City, will deliver a lecture on May 8 at 6 P M, on "The Psychological Basis of the 'Project Method,'" in the Library of the Central Hall, Westminster, S W 1 Tickets (price 1s) can be obtained from the secretary, New Education Fellowship, 11 Tavistock Square, W C 1

A SUMMER tour to Norway, leaving Newcastle on July 27, is being arranged by the Educational Travel Association Shore excursions under competent guidance will be made for studies in the fiord region, and an extension overland will be made to the sub arctic area of the tableland and to Oslo for the ethnological exhibits of Eskimo life collected by Amundsen, and the geological, botanical, and archæological collections there Particulars may be obtained by sending a 2d stamp to the honorary secretary, E T A, c/o the Cheshire Training College, Crewe

A SUMMER school of biology under the direction of Prof F A E Crew, is being organised by the Education Committee for the County Borough of Brighton, to be held at the Municipal Training College on Aug 2–16 Courses will be given on biology and the school curriculum (Prof A D Peacock, University of St Andrews, and Mr G B Walsh, High School for Boys Scarborough), on the theory of the cell, the gene, and organic inheritance in man (Prof F A E Crew), and there will be single lectures on special topics Practical and field work is being arranged Particulars can be obtained from the secretary to the Brighton Education Committee, Mr F H Toyne 54 Old Steine, Brighton

PARTICULARS of vacation courses to be held in Great Britain in 1929 are given in a pamphlet recently issued by the Board of Education There will be courses in science subjects in England and Wales as follows arranged by the Board for teachers only in physics at Cambridge and Harrow, in chemistry at Oxford, in biology at Cambridge, in engineering at Oxford, and in gas technology at Leeds, arranged by local education authorities—in chemistry at Nantwich, in biology at Brighton, Nantwich, and Bingley, in rural science at Barry (South Wales), in mining and engineering at Swansea, and in regional survey at Folkestone, organised by university bodies —in biology at Cambridge, Great Ayton (Yorks), and at or near Birmingham, in psychology at Cambridge, Oxford, Bristol, Rocester (Staffs), Chester, Bangor, and Harlech, organised by other bodies—in mine survey and economic geology at Camborne, in regional survey at Stratford on Avon, and in psychology of handwork at Chester A novel course in mothercraft, organised by the Board for teachers in elementary schools, will be held in London on July 22–Aug 2 Only three courses for foreigners are announced, to be held at Cambridge, London, and at Exeter The Board has this year, for the first time, included in the pamphlet particulars of vacation courses in Scotland, namely, courses for teachers arranged by the National Committee for the Training of Teachers, and courses, planned to be completed in two summers, of the ordinary university degree standard, to be held at Edinburgh in mathematics, physics, geography, and biology

Calendar of Patent Records.

May 6, 1845 —The introduction of the electric telegraph and its rapid progress were mainly due to the united efforts of Sir Charles Wheatstone and Sir William Fothergill Cooke, who, approaching the subject one from the scientific and the other from the business point of view, were brought together at a time when many attempts were being made to devise a practical system Their first patent was taken out in 1837 But complete success was not achieved until they produced the single needle telegraph, which was patented by them on May 6, 1845 A special Act of Parliament was passed to permit the formation of a company of more than twelve persons (the maximum number allowed under the various grants) to work this and all the earlier patents of the two inventors

May 7, 1794 —The first real gas engine was the invention of Robert Street, who patented it on May 7, 1794, under the title "A new invented method to produce an inflammable vapour force by means of liquid, air, fire, and flame, for communicating motion to engines and machinery" In Street's engine, a few drops of spirit of turpentine are introduced into the cylinder the bottom of which is kept heated so that the spirit is instantly converted into vapour The piston is at the same time moved upwards, and a quantity of air thereby sucked into the cylinder, which mixes with the vapour and forms an explosive mixture which is ignited by a flame applied to a touch hole

May 7, 1802 —The corkscrew now in common use in which the prong is fixed to the end of a right handed screw which works in a hollow quick left handed screw working in a hollow cylinder shaped to fit over the bottle mouth, so that the cork is pierced and extracted by one continuous right handed turning of the handle, was patented by Sir Edward Thomason of Birmingham on May 7, 1802 During the term of the patent more than 130,000 corkscrews of this type were made at prices ranging from one guinea to four shillings

May 9, 1807 —Sir William Cubitt's invention for automatically varying the area of sail in a windmill according to the strength of the wind was patented on May 9, 1807 Cubitt substituted movable shutters for the sail fabric, and geared the shutters to a rod running through the centre of the wind shaft, so that the opening and closing movements of the shutters were communicated to the rod A hanging weight attached to the end of the rod was adjusted to keep the shutters at the most suitable angle, but allowed them to open to present less effective surface to the wind when this became stronger than normal This mechanism and the earlier invention of Andrew Meikle for automatically keeping the sails into the wind were extensively adopted and are still in use in England, but were not taken up on the Continent

May 9, 1865 —The first application of hydraulic power for the operation of tools was Ralph Hart Tweddell's invention for fixing or tightening the ends of boiler tubes by means of expanding dies operated by hydraulic or other fluid pressure, which was patented on May 9, 1865 The invention was immediately successful and resulted in a reduction of more than one fourth in the cost of riveting

May 10, 1837 —The manufacture of galvanised iron is due to two Frenchmen, Ledru and Sorel, of Paris, who were granted a French patent for their invention on May 10, 1837, and followed this with twenty three patents of improvement between that date and 1846 The English patent was sealed in the name of Craufurd in April 1837

Societies and Academies.

LONDON

Royal Meteorological Society, April 17.—The late **W. H. Dines** and **L. H. G. Dines**: Monthly mean values of radiation from various parts of the sky at Benson, Oxfordshire. Records for the five years 1922–1926 are given. The radiation is dealt with under two heads: (1) Luminous rays; (2) dark heat rays of wave length exceeding about 2 μ; each is measured under conditions of (1) clear skies, (2) completely overcast skies.—**L. H. G. Dines**: An analysis of the changes of temperature with height in the stratosphere over the British Isles. The average temperature distribution in the stratosphere over the British Isles consists of a pronounced inversion of 3° C. at the bottom, followed by a lapse of about 0·5° C. per km. from (H_c+3) km. upwards to at least (H_c+8). There is no significant connexion between the magnitude of the inversion and either the lapse rate just below it, or the temperature in the troposphere in the layer $3\frac{1}{2}$ to $7\frac{1}{2}$ km. Such evidence as is available is against the existence of a diurnal variation of temperature in the stratosphere.—**H. A. Hunt**: A basis for seasonal forecasting in Australia. A fairly definite four year cycle is indicated, consisting of two dry years followed by two wet years, and requiring two years to be allotted to the drying and heating phase and two to the wetting and cooling. The four year period in the rainfall is also fairly well marked in the percentage of the continental area over which the rainfall is above the average each year.

PARIS

Academy of Sciences, Mar. 25.—**P. Villard**: Associations and forms of clouds. Discussion of the relations between the forms of clouds and production of rain.—**F. E. Fournier**: A means of extending French trade.—**Alex Véronnet**: There are three distinct spaces and three only: Euclid, Riemann, and Cartan.—**R. Chambaud**: The deformation of arches.—**J. H. Coblyn**: Diagrams and monograms.—**H. Weiss** and **E. Vellinger**: The measurement of the interfacial tension between mineral oils and aqueous solutions. The influence of time and of the hydrogen ion concentration. The interfacial tension of a system mineral oil–aqueous solution of electrolyte depends not only on the hydrogen ion concentration of the aqueous phase but also on the nature of the electrolytes utilised. But the variations due to the nature of the electrolytes are negligible as a first approximation compared with those brought about by the variations of the hydrogen ion concentration.—**F. Prevet**: The influence of boric acid on the phosphorescence of zinc sulphides prepared by the explosion method. The phosphorescent zinc sulphide prepared with boric acid is unaffected by air and moisture. There is a marked increase in the luminosity of the product.—**Pierre Leroux**: Study of the absorption of a specimen of blue rock salt. A study of the variation of the absorption of blue rock salt as a function of the wave length and of the temperature.—**Jean Cabannes** and **Pierre Salvaire**: The enlargement and displacement of the lines of the spectrum by molecular diffusion.—**M. Ponte**: Electronic analysis: lattice of the oxides of magnesium, zinc, and cadmium. The experimental results given permit of the conclusion being drawn that for the velocities of electrons utilised, electronic analysis is at least as accurate as analysis by X-rays, and may be used with confidence.—**E. Sevin**: The photoelectric effect and the continuous X-spectrum.—**André Michel** and **Pierre Benazet**: The reheating of austenitic steels.—**Léon Lortie**: The combinations of the salts of tetravalent cerium and of thorium with sodium carbonate (sodium cericarbonate and thoricarbonate). The ceric salt $Na_6Ce(CO_3)_5+12H_2O$ has been isolated in crystals. A thorium salt of analogous composition has also been isolated.—**L. Jacqué**: The fusibility of the ferro-calcium alloys.—**R. Cornubert** and **Ch. Borrel**: Anomalies of condensation and of cyclisation. Studies on the condensation products of α-methyl-α'-cyclopentanone and benzaldehyde in the presence of hydrochloric acid.—**J. Bougault** and **Mlle. Bl. Leroy**: Phenyloxymaloic anhydride. This substance gives crystallised compounds with amines, insoluble in ether: useful for the characterisation of the amines.—**A. Demay**: The antestephanian tectonic of the central French plateau to the east of the Loire.—**René Bréon**: Observations on beach deposits. In the bay of Authie pebbles and fragments of rocks are found which appear to have been transported at least 250–300 kilometres from the coast of the south of England. It is impossible for these to have been carried in suspension like sand, and the question as to the means of transportation is difficult of solution. One single specimen of rock had attached to it remains of *Fucus saccharinus*, and the author suggests that seaweed attached to the rocks may have been the cause of the flotation.—**A. Vincent**: The electrification of winds charged with snow. Winds charged with frozen snow caused the development of high potentials in an aerial capable of giving sparks up to 5 mm. in length.—**Joseph Devaux**: The measurement of the absorption factor of the surface of some Pyrenees glaciers for the solar radiations. If the surface of the glaciers consisted of pure ice limited by a plane surface, about 98 per cent would be absorbed. The absorption factors found were between 0·4 and 0·77, the lower value being undoubtedly due to the extensive alterations in the surface of the glaciers.—**I. D. Streinikov**: The ecological conditions of existence of the fauna of the Kara Sea.—**C. Chabrolin**: The decay of the inflorescence of the date palm (Khamedj). The author confirms the conclusions of Cavara that this disease is due to the parasite *Manginiella Scættæ*. The most practical treatment appears to be dusting the terminal bud with a mixture of powdered copper sulphate and slaked lime.—**Jules Amar**: Sex and nutrition.—**Serge Yourlevitch**: The principal characters of the ocular movements. A summary of the results of a kinematographic study of more than 20,000 movements of the eye.—**Jacques Pellegrin**: The Cichlidæ of Madagascar.—**E. Voisenet**: New researches on the nature of the substance which produces the bitter taste in the disease of bitter wines. A description of the isolation of a very bitter substance, a derivative of acrolein, from 40 litres of wine attacked by the disease.—**H. Colin** and **Marc Simonet**: The viscous fermentation of the frozen beet. The viscous material is produced by a coccus at the expense of the sugar. The coccus has been isolated and cultivated. The viscous material appears to be identical with the dextrane previously isolated by various authors from sugar refinery juice contaminated with *Leuconostoc mesenteroides*.—**Ducloux**, **Rinjard**, and **Mlle. Cordier**: The symbiosis *in vivo* of the virus of Borrel's pustule in sheep and the virus of foot and mouth disease.

April 2.—**A. Lacroix**: A meteorite which fell at Beyrout (Syria) on Dec. 31, 1921.—**L. Léger** and **O. Duboscq**: *Harpella melusinæ*, an eccriniform entophyte parasite of the larvæ of *Simulium*.—**J. A. Schouten**: The geometrical significance of the semi-symmetrical property of an integral connexion which leaves the fundamental tensor invariant.—**C. Bonnier**: The determination of the

temperatures in explosion motors —Georges Mignonac and René Vanier de Saint-Aunay The polymerisation of acetylene by the silent discharge The synthesis of dipropargyl and of its isomers The complicated mixture produced by the action of the silent discharge on acetylene consists partly of a primary condensation product due to the discharge alone and partly of the secondary polymerisation of this by heat By carrying out the reaction at 60° C the hydrocarbons dipropargyl, methylpentadiine and a hexadiene were isolated —Pierre Bedos and Adrien Ruyer The dehydration of the oxide of cyclohexene and the passage from the C_6 ring to the C_5 ring Cyclohexene oxide can be dehydrated by phthalic anhydride giving 1 3 cyclohexadiene and this is generally accompanied with isomerisation of the oxide to cyclopentane aldehyde —Paul Lemoine The superposition of a Tertiary anticline on a Cretaceous syncline

Academy of Sciences (*Comptes rendus* No 24 1928) S Borovik and Afanasjeva Influence of a vacuum on the radium clock Some improvements in the Strutt radium clock are offered and a method of making exact measurements with it of the pressure in relative vacua A Lukašuk Helium in some thorium minerals of Russia The quantity of helium found in four minerals examined was as follows chevkinite 0 109 c c eshinite 0 648 c c ortite 0 0638 c c monatsit 0 287 c c in one gram of the mineral P Svetlov Osmotic pressure and the permeability of membranes of trout eggs External membrane is permeable to electrolytes organic molecules and colloid particles Osmotic pressure in the yolk of the eggs is constant throughout the period of development so that some unknown mechanism for the regulation of the pressure must be present B Stegmann A preliminary communication on an ornithological expedition in the upper and middle course of the Amur and in the western part of the Stanovoi ridge Notes on distribution nesting habits etc of a number of local bird species C Flerov Preliminary note on the diagnostic characters in the genus *Moschus* Linn (Mammalia, Cervidæ) A brief review of musk deers containing diagnoses of five subspecies of *Moschus moschiferus* (including two new ones namely, *arcticus*, from north east Siberia and *sachalinensis* from Sakhalin Island) two subspecies of *M chrysogaster* and of a new species *M berezovskii*, from the Sze chuan province of China

(*Comptes rendus* No 25, 1928) B Schtylko Fossil remains of a pike from the Akmolinsk province The remains are those of a *dentale*, and their study showed no differences from the *Esox lucius*, and it may be suggested that the latter species existed already in the Pleistocene A Mordvilko *Geoica* Hart and its anolocyclic forms Plant lice of the genus *Pemphigetum* Mordv, forming galls on *Pistachia* trees proved to be able to migrate to roots of grasses, where they have been long known under the name

Geoica The *Geoica* root form occurs in the areas where there are no *Pistachia* at present (North America), but it is possible to state definitely that the trees grew there in previous geological ages, with their disappearance only the grass root form of the aphid remained —**G Lindberg** Southern elements in the fish fauna of the Bay of Peter the Great (Sea of Japan) The fauna differs strikingly from that of the Okhotsk and the Bering Seas in its subtropical character, while including a number of typical Arctic forms, many of which, however, penetrate as far south as the Korean coasts At the same time, a number of southern forms are in their turn met with as far north as Vladivostok and Olga Bay

Melbourne

Royal Society of Victoria, Dec 13 **Edwin S Hills** The geology and palæontology of the Cathedral Range and the Blue Hills, in North Western Gippsland This range is a double razorback composed of two beds of hard sandstone separated by softer shales and sandstones Although formerly believed to be Upper Palæozoic in age, they are overlain with a strong unconformity by Upper Devonian rhyolites, basalts, tuffs and sediments outcropping to the east and are apparently conformable with Upper Silurian sediments which outcrop to the west The Cathedral Beds have as yet yielded no fossils, but in the Upper Devonian rocks a new fish fauna was discovered —**F Chapman** (1) On a fine example of the flanged cowrie *Cypræa gastroplax* McCoy The subgenus *Palliocypræa* to which the species was referred by M Cossmann is here given generic rank The shell structure is discussed —(2) On some trilobites and brachiopods from the Mount Isa District North West Queensland For many years these beds were referred to as schists of unknown age The rock in which the fossils are preserved is a cherty shale, horizontally bedded and found twelve miles west of Mount Isa at the head of the Templeton River The assemblage of fossils indicates a middle to upper Cambrian horizon —(3) On a new species of *Capulus* found attached to a *Pterygotus* carapace Some attached univalves, *Capulus melbournensis*, adherent to the counterpart of the Silurian *Pterygotus* somite which was described by McCoy in 1899 This palæozoic *Capulus* shows, in its habit and form, a close resemblance to the related tertiary genus *Hipponix*

Vienna

Academy of Sciences, Jan 31 —**E Haschek** On Talbot's Law **M Eisler** and **L Portheim** Further researches on the nicotine poisoning of fruits and seeds In *Nicotiana* and *Avena*, the alkaloid penetrates unhindered through the husk, in *Fagopyrum* with difficulty in *Helianthus* scarcely at all The embryos are unequally resistant to nicotine Calcium and potassium chlorides influence the degree of poisoning —**L Mirskaja** Regenerative processes in growing points of *Tradescantia guianensis* —**M Holly** Some new African fish forms Species of *Barbus* from rivers

Feb 8 —**R Wegscheider** Reactions in light and in the dark with counter and following effects —**L Moser** and **A Brukl** Determination and separation of rare metals from other metals (15) The quantitative analysis of gallium For separation of little gallium from much iron, sodium thiosulphate was used, this reduces ferric to ferrous and precipitates gallium —**F Staudinger** Heteromorphoses in stigmata and other organs of *Carausius morosus* —**H Burchardt** Regeneration and symmetry of limbs stuck through the bodies of newts —**C Zawisch-Ossenitz** The promotion of bone growth by injection of bone extract

Feb 14 —**A Kailan** and **G Brunner** Velocity of esterification of alcohols in formic acid —**O Gugenberger** The Brachiopoda of the Cardita strata at Launsdorf in Middle Carinthia —**O Gugenberger** Upper Triassic Cephalopoda and Brachiopoda from Plakles on the Hohe Wand —**R E Mark** Researches on the influence of various altitudes on the action of the thyroid gland in the dog —**K Federhofer** Graphical kinematics of a crank loop oscillating in space

Diary of Societies

FRIDAY May 3

Iron and Steel Institute (Annual Meeting) (at Institution of Civil Engineers) at 10 a m —Announcement of the award of the Andrew Carnegie Research Scholarships for 1929 30 —Presentation of the Carnegie Gold Medal to Dr A Bramley—The Hon Sir Charles Parsons and H M Duncan A New Method for the Production of Sound Steel —Third Report on Heterogeneity of Steel Ingots by a Committee of the Institute —J M Robertson The Microstructure of Rapidly Cooled Steel —D Lewis The Transformation of Austenite into Martensite in a 0·8 per cent Carbon Steel —A L Norbury Constitutional Diagrams for Cast Irons and Quenched Steels —At 2 30 —G R Bolsover Brittleness in Mild Steel —J B Pfeil The Oxidation of Iron and Steel at High Temperatures —E G Herbert and P Whitaker The Differential Method for Measuring the Thickness of Hard Cases without Sectioning them —T E Rooney and G Barr A Method for the Estimation of Hydrogen in Steel

Royal Society of Medicine (Otology Section) (Annual General Meeting) at 10 30 a m —The Treatment of Chronic Deafness —Dr D McKenzie The Symptomatic Treatment of Deafness H Kisch Chronic Deafness Its Treatment and Prevention —T Neville Chronic Deafness —G S Hett and A G Wells Ionisation as a Treatment for Middle ear Suppuration

Royal Astronomical Society (Geophysical Discussion) at 4 30 —Cloud Formation C J P Cave Sir Gilbert Walker Chairman Sir Frank Dyson

Royal Society of Medicine (Laryngology Section) (Annual General Meeting) at 5 —F I Cleminson Treatment of Carcinoma of the Œsophagus by Radium

Philological Society (at University College) at 5 30 —Anniversary Meeting

Institution of Electrical Engineers (Meter and Instrument Section) at 7 —G D Malcolm Chairman's Address

Institution of Mechanical Engineers (Informal Meeting) at 7 —H Barry London's Water

Geologists' Association (at University College), at 7 30 —Dr S W Wooldridge and A. J Bull The Arun Gap and Lower Greensand around Pulborough

Institution of Automobile Engineers (jointly with Institution of Production Engineers) (at Royal Society of Arts) at 7 45 —H F J Orcutt The Production and Application of Ground Gears (Lecture)

Royal Society of Medicine (Anæsthetics Section) (Annual General Meeting), at 8.30 —Dr H Sington Pre medication by Paraldehyde in Children

Royal Institution of Great Britain at 9 —Sir Daniel Hall The Garden Tulip

SATURDAY, May 4

Institution of Municipal and County Engineers (Eastern District) (at Red Lion Hotel, Cromer) at 1

Institution of Municipal and County Engineers (South Eastern District) (at Aerodrome Hotel Croydon), at 2 15 —G A Ballard Town Planning and Municipal Airports.

MONDAY May 6

Cambridge Philosophical Society (in Botany School) at 4 30 —A H K Petrie On the Ionic Equilibria of Plant Tissues.—R. G Tomkins Mould Growth and Atmospheric Humidity —R. D Whyte The Cytological Basis of Partial Dioecism in Plants.—*Papers to be communicated by title only* —C Pellew The Genetics of Unlike Reciprocal Hybrids —A. R Shull Determination of Types of Individuals in Aphids, Rotifers and Cladocera.—J A Bierens de Haan Animal Language and its Relation to that of Man —G Koller Internal Secretions in Invertebrate Animals

ROYAL SOCIETY OF EDINBURGH at 4 30 — G N Hunter Colour Sensitivity — Dr E B Ludlam and R B Mooney The Influence of Air and Moisture on the Budde Effect in Bromine — A C Stephen Studies on the Scottish Marine Fauna The Fauna of the Sandy and Muddy Areas of the Tidal Zone — George Redington Study of the Effect of Diurnal Periodicity upon Plant Growth — Dr Margery Knight Studies in the Ectocarpaceæ II Life History and Cytology of *Ectocarpus siliculosus* Dillw — *to be read by title only* — Miss Mary H Latham Jurassic and Kainozoic Corals from Somaliland — Dr S Goldstein On the Asymptotic Expansion of the Characteristic Numbers of the Mathieu Equation

VICTORIA INSTITUTE (at Central Buildings Westminster), at 4 30 — Rev Canon A Lukyn Williams Early Anti Judaica—the Books of Testimonies

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5 — Dr G C Simpson The Importance of Climatic Stations in Polar Regions

ROYAL INSTITUTION OF GREAT BRITAIN at 5 — General Meeting

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College) at 6 — Dr R B Raup Is there a Psychology for Modern Education?

RAILWAY CLUB (at 57 Fetter Lane) at 7 30 — D D Battie A Thirty Years Survey

ROYAL SOCIETY OF ARTS, at 8 — Sir E Denison Ross Nomadic Movements in Asia (Cantor Lectures) (IV)

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society) at 8 — Dr T Moran Recent Advances in the Low temperature Preservation of Foodstuffs

SURVEYORS INSTITUTION at 8 — H F Bidder and W V Graham Rights in Underground Water

TUESDAY, MAY 7

ROYAL SOCIETY OF MEDICINE (Orthopedics Section) at 5 30 — Annual General Meeting

ZOOLOGICAL SOCIETY OF LONDON at 5 30 — Major S S Flower Exhibition of the Centenary Edition of the Vertebrate List Vol I, Mammals — F Martin Duncan Exhibition of Cinematograph Films of North American Big Game presented to the Society by Mr Prentiss N Gray — E B Worthington New Species of Fish from the Albert Nyanza and Lake Kioga — W Rowan A Hermaphrodite Spiny Dogfish (*Squalus sucklei*)

LONDON NATURAL HISTORY SOCIETY (at Winchester House E C) at 6 30 — T J Evans Life in the Deep Sea

INSTITUTE OF MARINE ENGINEERS at 6 30 — W J Muller Notes on the Lentz Standard Marine Engine as Fitted to Ships of the Koninklijke Paketvaart Maatschappij (Royal Packet Line) Amsterdam

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7

INSTITUTE OF METALS (at Institution of Mechanical Engineers) at 8 — Sir Oliver Lodge Some Ideas about Metals (Annual May Lecture)

TELEVISION SOCIETY (at Engineers Club Coventry Street) at 8 — Capt R Wilson and A A Waters Some Practical Considerations in the Building of Television Apparatus — Demonstrations Model Showing Mechanical Exploring as the Speed of the Disc Increases from Zero R R Poole — Model of Talking Film Projector H S Ryland

WEDNESDAY MAY 8

ROYAL SOCIETY OF MEDICINE (Surgery Sub Section of Proctology) (Annual General Meeting) at 4 45 — At 5 — Discussion on Fistula in ano

GEOLOGICAL SOCIETY OF LONDON at 5 30 — F M Trotter The Glaciation of Eastern Edenside the Alston Block and the Carlisle Plain — J A Douglas A Marine Triassic Fauna from Eastern Persia.

ROYAL SOCIETY OF ARTS at 8.

ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Polytechnic Institute) at 8 15 — Dr H O Cocks Some Possible Uses of Alternating Currents in Electrodeposition

INSTITUTION OF CHEMICAL ENGINEERS (Jointly with Institute of Fuel) — Discussion on The Scope of the Chemical Engineer in Relation to the Fuel Consuming Industries

THURSDAY MAY 9

ROYAL SOCIETY, at 4 30 — R H Fowler and Dr P Kapitza Magnetostriction and the Phenomena of the Curie Point — Prof C G Darwin A Collision Problem in the Wave Mechanics — J A Gaunt The Relativistic Theory of an Atom with many Electrons — R de L Kronig The Quantum Theory of Dispersion in Metallic Conductors — *Papers to be read by title only* — F J Wilkins The Kinetics of the Oxidation of Copper Part I — C E Eddy Prof T H Laby and A H Turner Analysis by X Ray Spectroscopy — M C Johnson The Adsorption of Hydrogen on the Surface of an Electrodeless Discharge Tube — A Elliott The Absorption Band Spectrum of Chlorine — H W Thompson and C N Hinshelwood The Influence of Nitrogen Peroxide on the Combination of Hydrogen and Oxygen — H J Phelps and R A Peters The Influence of Hydrogen Ion Concentration on the Absorption of Weak Electrolytes by Pure Charcoals — Dr H T Flint The First and Second Order Equations of the Quantum Theory — S Bhagavantam The Magnetic Anisotropy of Naphthalene Crystals — A H Wilson Perturbation Theory in Quantum Mechanics II — C G Lyons and Dr E K Rideal On the Stability of Unimolecular Films Parts I II and III — P A M Dirac Quantum Mechanics of Many Electron Systems — Prof O W Richardson and P M Davidson The Spectrum of H_2. The Bands Analogous to the Parhelium Line Spectrum Parts III and IV — H E Hurst The Suspension of Sand in Water — D Brunt The Transfer of Heat by Radiation and Turbulence in the Lower Atmosphere — R K Asundi The Third Positive Carbon and Associated Bands — Prof G I Taylor The Criterion for Turbulence in Curved Pipes — W G Bickley Hydrodynamic Forces acting on a Cylinder in Motion, and the Idea of a Hydrodynamic Centre — M L E Oliphant The Action of Metastable Atoms of Helium on a Metal Surface — J Hargreaves The Effect of a Nuclear Spin on the Optical Spectra — Prof M N Saha and Ramesh Chandra New Methods in Statistical Mechanics — N F Mott The Interpretation of the Wave Equation for Two Electrons.

INSTITUTE OF PATHOLOGY AND RESEARCH (St. Mary's Hospital, W 2), at 5 — Dr E D Adrian The Nervous Mechanism of Sensation and Movement.

INSTITUTION OF ELECTRICAL ENGINEERS at 6 — Annual General Meeting

IRON AND STEEL INSTITUTE (at Royal Technical College Glasgow), at 7 — Discussion on A New Method for the Production of Sound Steel by the Hon Sir Charles Parsons and H M Duncan — Third Report on Heterogeneity of Steel Ingots by a Committee of the Institute — First Report on Blast Furnace Plant and Practice, by a Committee of the Institute — Twenty Months Results of Dry Blast Operation, by E H Lewis. — The A I B Sinter Plant at Messrs Guest, Keen and Nettlefolds, Ltd, Cardiff Works by W E Simons

OIL AND COLOUR CHEMISTS ASSOCIATION (at 30 Russell Square), at 7 — F Fancutt Painting as it Affects the Railways

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Colour Group), at 7

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7 30 — T H Court and Dr M von Rohr Contributions to the History of the Spectacle Makers Company (Second Paper on the Court Collection).

ROYAL SOCIETY OF MEDICINE (Neurology Section) at 8 30. — Annual General Meeting

FRIDAY MAY 10

ROYAL ASTRONOMICAL SOCIETY at 5 — Prof E Hertzsprung The Pleiades (George Darwin Lecture). — E A Kreiken On the Dwarf Nature of Double Stars

PHYSICAL SOCIETY (at Imperial College of Science), at 5 — Dr W E Sumpner Heaviside's Fractional Differentiator — J H Awbery A Simple Method of Fitting a Straight Line to a Series of Observations. — E W H Selwyn Arc Spectra in the Region λ1600 λ2100 — Dr K R Rao The Spectrum of Trebly ionised Thallium — G A Wedgwood The Elastic Properties of Thick Cylindrical Shells under Internal Pressure — A Demonstration relating to Standards of Length and Mass by J E Sears

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (at Abbey Hotel, Kenilworth) at 5 30 — Discussion on Stare Bridge D H Brown Kenilworth Castle and Town S Douglas

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30 — Annual General Meeting

MALACOLOGICAL SOCIETY OF LONDON (in Zoological Department, University College) at 6

ROYAL SOCIETY OF ARTS (Indian Meeting) at 8 — Captain P Johnston Saint An Outline of the History of Medicine in India (Sir George Birdwood Memorial Lecture)

ROYAL INSTITUTION OF GREAT BRITAIN at 9 Prof A E Boycott The Twist of Snail Shells

SATURDAY MAY 11

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South Wales District) (at Council Chamber Swansea) at 3 15 — Discussion on Some Road and Other Schemes at Swansea, R Hodson Swansea Main Drainage Scheme and Flood Relief Schemes J Hassall Llansamlet Sewage Pumping Scheme Swansea, M E Habershon

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Sections) (at Harrogate).

PUBLIC LECTURES

FRIDAY MAY 3

UNIVERSITY COLLEGE at 4 — Prof A J Hall Some of the Sequels of Epidemic Encephalitis (Lethargica) — At 5 30 (Succeeding Lecture on May 10) — Prof R Robinson Public Inaugural Lecture

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY at 5 30 — Prof F O Bower The Origin of a Land Flora reviewed 21 Years after Publication (Huxley Memorial Lecture)

TUESDAY MAY 7

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY — ROYAL SCHOOL OF MINES at 5 30 — Prof E de Margerie Some Aspects of French Tectonics (Succeeding Lectures on May 10 and 13)

INSTITUTE OF METALS (at Institution of Mechanical Engineers), at 8 — Sir Oliver Lodge Some Ideas about Metals (Annual May Lecture)

WEDNESDAY, MAY 8

UNIVERSITY OF BIRMINGHAM, at 4 30 — Dr C Singer Medicine and the Revival of Learning

CONGRESSES

MAY 6 TO 11

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY (in London) — Subjects to be discussed — The Evacuation of Sick and Wounded by Air and Water, Tropical Fevers of Short Duration, Injuries to Blood vessels and their Sequelæ Physical and Chemical Analysis of the Glass and Rubber Articles Employed by the Medical Services The Standard of Dental and Physical Fitness in the Various Military Services

MAY 15 TO MAY 20

ROYAL INSTITUTE OF PUBLIC HEALTH CONGRESS (at Zurich).

Section I — State Medicine and Municipal Social Hygiene
Section II — Industrial Hygiene and Industrial Diseases
Section III — Child Welfare, School Hygiene and Women and Public Health
Section IV — Pathology, Bacteriology, and Biochemistry
Section V — Tuberculosis
Section VI — Climatology and Sports Hygiene
Section VII — Veterinary Medicine and Meat Hygiene

MAY 15 TO MAY 28

WORLD POWER CONFERENCE ON COMPLETE UTILISATION OF WATER POWER RESOURCES (at Barcelona) — Subjects to be dealt with — General Hydrological Problems Technical Problems of Water Power Utilisation Economic and Financial Problems Legal Problems, Protective Measures and Defence Works of Undertakings

SATURDAY, MAY 11, 1929.

No 3106, Vol 123]

A Royal Commission on the Civil Service

AT the last meeting of the National Whitley Council for the Civil Service, the staff side, at the instance of the Institution of Professional Civil Servants, moved for the appointment of a joint committee of the Council in the following terms

That a joint committee be appointed to inquire into the recruitment, organisation, duties, and pay of the professional, scientific, and technical Civil Servants employed in the scientific, research, and experimental branches of the Public Service, and to make recommendations

In reply, the official side of the Council, speaking on behalf of the Government, stated that while the motion for such a committee could not be accepted, the Government had decided to set up an inquiry into the organisation and lay out of the research departments, upon which persons outside the Civil Service familiar with the problems involved would be invited to serve The Institution, while not satisfied that the views of the staffs it represented would be adequately considered by such an inquiry, decided to await further information before settling the policy it should adopt, and to call an early meeting of the standing joint committee of the Institution and the Association of Scientific Workers

Two days after the meeting of the National Whitley Council, the Prime Minister unexpectedly announced to a women's deputation, not primarily concerned with Civil Service questions, that if returned to power the Government had decided to set up a Royal Commission on the Civil Service, with, it appears, wide terms of reference which would permit of a radical re examination of the structure and organisation of the Service This announcement was received with surprise in official circles, and it was thought in some quarters that the Royal Commission would, in view of the character of its proposed reference, take within its scope the inquiry concerning the research departments The Institution has made inquiries through the staff side of the National Whitley Council, and learns that two separate inquiries are in fact intended

It is all to the good that the special problem of the organisation of research under the auspices of the State should receive expert and impartial consideration The recent Report of the Research Co ordination Sub-Committee of the Committee of Civil Research indicated that there was scope for closer co ordination in certain directions, and better organisation and concentration of control

should lead to a higher status for the research departments, and so to better conditions for the scientific staffs, which lag far behind those of non-scientific civil servants But it is to be hoped that the Royal Commission will be so constituted as to ensure that, in the consideration of the structure of the Civil Service, due regard will be paid to the views of those who hold that science is an integral part of the life of civilised communities, and that economical administration requires a full recognition of the contribution that the technical expert in the wide sense can make towards the promotion of social welfare In the Civil Service the technical expert has little or no authority and is normally regarded as a mere consultant, with the result that his career and status are adjusted accordingly The control of the Service by a close caste of administrators, few of whom have received an advanced scientific training, has inevitable reactions on the part that the man of science, whether pure or applied, is permitted to play in administration Status in the Civil Service, as elsewhere, is reflected in remuneration, and Sir Richard Redmayne has recently pointed out in his presidential address to the Institution of Professional Civil Servants that the highest scientific posts in the Service carry half the salary of the highest administrative posts

The modern State cannot afford to treat in this fashion those upon whom material progress depends Efficiency of the administrative machine must depend upon a ready acceptance of the results of research and appreciation of the need for the scientific approach in the solution of administrative problems A Royal Commission which does not include a number of scientific and professional men of acknowledged authority and experienced in the application of scientific method and discovery to administrative necessities will inevitably produce a report highly coloured by traditional 'establishment' notions in the Civil Service, which will rivet upon the Service for yet another generation a system of control now some two generations old and completely out of touch with modern necessities Mr Churchill, in reply to a parliamentary question, has stated that the object of the Royal Commission is to undertake "a dispassionate and informed examination of the Civil Service from the point of view of its efficiency as a national instrument and of its own well-being" These words are admirable, but we shall await with interest the actual terms of reference, and above all the actual personnel of the Commission

Rays and Waves

(1) *Handbuch der Experimentalphysik* Herausgegeben von W Wien und F Harms Unter Mitarbeit von H Lenz Band 15 *Radioaktivität* Von Prof K W F Kohlrausch Pp xii + 985 81 gold marks (2) Band 18 *Wellenoptik und Polarisation* Bearbeitet von K F Bottlinger, R Ladenburg, M v Laue, Hans Schulz *Photochemie*, von E Warburg Pp xiv + 674 63 50 gold marks (3) Band 19 *Dispersion und Absorption* Von Prof George Jaffé *Medien mit veränderlichem Brechungsindex und Lichtzerstreuung* Von Prof Richard Gans Pp viii + 430 41 gold marks (4) Band 23 *Phosphoreszenz und Fluoreszenz* Teil 1 Von P Lenard, Ferd Schmidt und R Tomaschek Pp xxiii + 741 71 gold marks (5) Band 23 *Phosphoreszenz und Fluoreszenz* Teil 2 Von P Lenard, Ferd Schmidt und R Tomaschek *Lichtelektrische Wirkung* Von P Lenard und A Becker Pp xi + 745 1544 72 gold marks (Leipzig Akademische Verlagsgesellschaft m b H , 1928)

TO the third book of Newton's "Opticks" are appended certain famous Queries, some of which are as applicable to day as when they were first written In Query 17 he asks "When a ray of light falls upon the surface of any pellucid body, and is there refracted or reflected, may not waves of vibrations, or tremors, be thereby excited in the refracting or reflecting medium at the point of incidence, and continue to arise there, and to be propagated from thence as long as they continue to arise and be propagated ? and are not these vibrations propagated from the point of incidence to great distances ? and do they not overtake the rays of light, and by overtaking them successively, do they not put them into the fits of easy reflexion and easy transmission described above ? "

In these days when waves of light pose as corpuscles or quanta, and material particles assume the characteristics of waves (albeit waves in space of many dimensions), the whole of modern physics might be included in the two terms 'rays' and 'waves' But these volumes of the monumental "Handbuch der Experimentalphysik" are more particularly concerned with light waves and the rays from radioactive substances, and there is no danger of misunderstanding when they are summarised under these two headings At the same time, the dilemma which confronts the physicist is reflected in the treatment meted out to the quantum theory by the different authors to whom

the work has been assigned Some accept the theory whole-heartedly, others with evident hesitation

(1) Prof Kohlrausch of Graz has written a complete and impartial account of the science of radioactivity, and we have nothing but praise to give to this admirable volume In some Continental textbooks we have noticed a tendency to belittle or to ignore the work of the Cavendish Laboratory and the Cambridge physicists No such tendency is to be found in this volume, where we meet repeatedly the names of J J Thomson, C T R Wilson, E Rutherford, and their numerous fellow workers The longest chapters in the book are devoted to gamma rays—a subject to which Prof Kohlrausch has made important contributions—beta rays, and alpha rays Very remarkable are the results obtained by the use of Wilson's cloud chamber, by means of which the tracks of such rays are made visible In particular, mention may be made of the stereoscopic pictures by Meitner and Freitag (Figs 169 and 170), in which the path of a hydrogen particle set in motion by the impact of an alpha ray is clearly marked Some of Blackett's photographs are also well reproduced We have taken special interest in the account of the H rays, including the description of Stetter's experiment, using Aston's mass spectroscope to show that the mass of such a particle is identical with the mass of the hydrogen atom

(2) The greater part of vol 18 is devoted to physical optics Rudolf Ladenburg gives an interesting critical account of the measurements of the velocity of light, taking Michelson's latest value, $c = 299{,}796$ km /sec , as a standard In an added note it is pointed out that this is in close agreement with the value deduced by the astronomical method (H Spencer Jones) [1]

M v Laue is responsible for valuable articles on the optics of moving bodies, the reflection and refraction of light at the interface between isotropic bodies, and the interference and diffraction of electromagnetic waves (with the exception of X rays) The first of these contains information as to recent researches not easily available to the student The same remark applies to Bottlinger's short article on the relativistic displacement of spectral lines towards the red and the bending of light in the gravitational field of a star The polarisation of light is well treated by Hans Schulz, who gives a careful account of historical and modern experiments and apparatus—we notice references are made to instruments by Hilger and by Bellingham and Stanley Reproductions are given of the striking interference patterns of crystals due to H Hauswald

A short article of 40 pages by E Warburg on photochemistry is included in this volume The author seems to have imposed severe restrictions on himself in his treatment of this subject, and the result is somewhat disappointing This arises in part from the complexity of the material, for although the quantum theory affords some explanation of the simpler photochemical processes, the reactions are in general complicated by secondary changes which cannot at present be traced in detail or subjected to critical analysis When absorption of incident radiation takes place, an electron is raised to a higher quantum level, or in other words, energy of radiation is transformed into quantum energy It is now assumed that, by interaction with another molecule, this quantum energy can be changed into another form of energy, in this case, chemical energy

To set up and preserve the laws of statistical equilibrium a particular process can in general never be supposed to act alone, unaccompanied by a corresponding reverse process , only the two together form a possible single mechanism of interaction Collisions between electrons and atomic systems may be divided into two types, those in which kinetic energy of electrons is changed into quantum energy of atomic systems, and those in which the inverse change of quantum energy into kinetic energy of electrons occurs In thermodynamic equilibrium there must be just as many collisions of one type as of the other According to Franck, this conclusion must also be drawn with regard to the collisions between excited and unexcited atomic systems

(3) Vol 19 of the 'Handbuch', though less bulky than some of its companions, deserves special attention, as it has to do with subjects of great theoretical importance Prof Jaffé, of Giessen, writes on the related topics of the dispersion and absorption of light After a short historical introduction the classical theories are discussed briefly but adequately The theory of dispersion was first suggested by Maxwell in a question in the Cambridge Mathematical Tripos of 1869, but important work was done by Sellmeier (1871), who independently advanced the view that the differences in the velocity of light in different materials must be attributed to the direct action of the vibrating particles of the medium set in oscillation by the ether vibrations The electromagnetic theory of dispersion is then described, and the

[1] See NATURE, vol. 120, p 602, 1927

later developments consequent upon the adoption of the electron theory discussed Next we have an account of the application of the quantum theory to the problem, leading up to the dispersion formula of Kramers, and finally to the new quantum mechanics—a truly notable record of scientific progress The experimental aspects of the sub ject are next taken up, gases, liquids, and solids being considered in turn, and comparison between theory and experiment being kept in view through out Chapter vi deals with several related questions of great interest, such as the number of dispersion electrons, and the probability of quantum transitions

Part II consists of three chapters dealing with absorption, commencing with an account of the theories, including the collision theory of Lorentz and also the theory of Planck, in which the damping is referred solely to radiation Then follow descriptions of experimental methods and of the results obtained for gases and vapours, liquids and solids The whole work is well done and deserves high praise

Prof Gans of Königsberg contributes a short chapter on media with variable refractive indices, and a further three chapters, which, in view of the growing importance of their subject, might well have been longer, on the molecular scattering of light

(4) The difficulty of dealing with the vast amount of material accumulating as the result of modern scientific research is illustrated by the volumes on phosphorescence and fluorescence The method, which consists in abstracting or reproducing in considerable detail a large number of original papers, is far from attractive In the opinion of the reviewer, who sympathises with the authors in their task, more severe pruning and more critical selection would have increased greatly the value of the resulting work We hold that the author of such a volume need not attempt to provide an exhaustive account of all available data, even were that humanly possible, but rather to supply a judicious and stimulating survey of the main facts and theories In the subject of luminescence the difficulty is acute, arising in part from the fact that the development of the theory has not kept pace with the increase in the number of facts of observation and experiment

The historical method is followed in the earlier part of the volume, which begins with an account of the observations of Canton, Stokes, and Becquerel, followed by a description of the work of Klatt (to whom the book is dedicated), of Lenard and his fellow workers, notably Hausser and Saeland We can do no more than mention the investigations of Gudden and Pohl on the electrical conductivity of phosphorescent materials when illuminated, and the work of the same investigators and of Schmidt on the dielectric constant of the material

(5) The second part of Vol 23 contains five chapters which conclude the discussion of phosphorescence and fluorescence, and five more covering some 500 pages which are concerned with photoelectric activity In the chapter on fluorescence, it is pointed out that the time during which the emission continues after the cessation of the stimulus does not afford a sharp criterion to enable us to distinguish between fluorescence and phosphorescence It is suggested that a better criterion may perhaps be found in the photoelectric effect, which postulates the complete separation of electrons from the active centres of the phosphore in all cases of phosphorescence of long duration

Of outstanding interest are the researches of R W Wood and others on the fluorescence of gases and vapours When sodium vapour is illuminated by sodium light, some of this light is re emitted without change of wave length as *resonance radiation* But, in addition, other monochromatic radiations, forming *resonance spectra*, are given out when the vapour is illuminated by the light of metallic arcs Recent investigations have done much to unravel the complicated line spectrum obtained in this way

The section on photoelectricity is mainly due to A Becker, and even if emphasis is laid on the work carried out by German investigators, it is useful to have the results summarised by one who has himself made important contributions to the subject We may mention in particular his work on the relation between photoelectric and thermionic emission The reviewer turned at once to the chapter on photoelectric fatigue, and was interested to find that this perplexing phenomenon is attributed by the author mainly to the influence of gas (ozone) or vapour (water vapour) on the emission of electrons The final chapter is on the practical applications of photoelectricity, and refers to the increasing importance of photoelectric cells in photometry

It was by studying the energy of photoelectric emission that Einstein in 1905 was led to the theory of light quanta, which seemed in direct antagonism to the wave theory of light The energy of the light quantum of frequency ν was assumed to be $h\nu$ where h is Planck's constant

We may conclude with a question put by Schrödinger at the end of his lectures on wave mechanics Is it quite certain that the conception of energy, indispensable as it is in macroscopic phenomena, has *any* other meaning in micro-mechanical phenomena than the number of vibrations in h seconds? H S ALLEN

The Evolution of Human Races

L'Ologenèse humaine (Ologénisme) Par Dr George Montandon Pp xi + 477 + 14 planches (Paris Félix Alcan, 1928) 200 francs

DR GEORGE MONTANDON is known to anthropologists because of the contributions he has made to our knowledge of the Mongoloid peoples of Asia, of the inhabitants of Abyssinia, and of the primitive cultures of Africa In the present imposing book he appears as the author of a work on systematic anthropology He has here attempted to do two quite separate things to give a systematic account of the living races of mankind—of which he distinguishes twenty—and at the same time to apply a new theory to explain the origin of human races The theory of evolution which he applies is that formulated by Prof Rosa of Modêna in 1918 and named by its originator 'ologenesi' (holos, entire) We think the author would have done much better to have written two books—one for the exposition of the theory he has adopted, and utilised the other for his valuable data and charts relating to the descriptive ethnology of mankind In brief, the theory is the weakest part of Dr Montandon's book, and many anthropologists may turn away before they reach the really valuable chapters We also think that the earlier chapters, which attempt to trace the origin of the earth and of life, might well have been omitted

After citing the various theories which have been formulated to explain the origin of new species—Lamarckism, Darwinism, neo Lamarckism, neo Darwinism, mutationism, etc —the author rejects them all in favour of Rosa's 'ologénisme', and proceeds to apply this theory to explain the facts of human evolution It is not necessary to enumerate all the postulates of his theory, they are numerous and arbitrary We need only mention two or three which are essential to understand its application to a race of human beings The theory presumes that every man, woman, and child of a race is 'wound-up', so that all, after passing through a certain number of generations, will arrive at a critical or maturation stage On this stage being reached the whole species divides, half of the individuals being changed into one kind of race, the other moiety into another Races 'unwind' and reach critical stages at different rates—some rapidly, others slowly—so that a backward race may be a true cousin of another which is highly advanced The theory is determinist in nature, but environment, habit, and competition are operative and modify the result Races have also arisen by hybridisation Further, as mankind is and has been distributed over wide areas of the world for long geological epochs, each area being the scene of independent advance, it is foolish to speak of, or search for, a limited area of origin or cradle for mankind Under this theory a new race appears at the same time over a wide area

In a brief notice such as this, it is impossible to give a full exposition of Dr Montandon's ideas, but enough has been stated to place the reader in possession of their trend Their practical application, even in Dr Montandon's hands, requires a considerable degree of constraint to make facts fit with expectation On the other hand, the author never shirks facts, he has searched all the latest literature dealing with blood reactions, immunity, etc, and sought to fit them into his scheme Indeed, the book is a valuable repository of fact, even if the theory of 'ologénisme' proves to have little or no permanent value

Chemistry and Physics of Sea Water

Biological Chemistry and Physics of Sea Water By H W Harvey (Cambridge Comparative Physiology Series) Pp x + 194 (Cambridge At the University Press, 1928) 10*s* 6*d* net

THIS book deals with the particular chemical and physical conditions in the sea which appear to be most important in affecting the growth of plants and animals The author reviews the results of researches subsequent to the publication of Krümmel's "Handbuch der Oceanographie" in 1911 Since H M S *Challenger* led the way in 1872, there has been a steady increase in the number of vessels investigating the high seas, while at the same time marine biological stations established in increasing numbers in different countries have investigated the conditions in coastal waters The combination of a laboratory on shore with a small sea going vessel has proved particularly fruitful, and provides the author with much of the material for this book

Chapter i gives a brief summary of the general physiology of marine organisms, the factors controlling photosynthesis, and the relation of the

animals to changes in oxygen tension, temperature, and light The part played by the so called dissolved organic matter is still obscure, but it is probably important Chapter ii deals with the chemical composition of the water, the dissolved salts and gases, and the hydrogen ion concentration Practical details for the estimation of the more important substances are given There is an interesting table of the elements occurring only in minute traces in the sea, of which there is a large number Many of these rare substances are extracted from the water by the organisms, and they may assist or even replace related substances in metabolic processes, as copper replaces iron in the respiratory pigments of the Crustacea

Recent work on the supply of food materials for the phytoplankton has shown that the nitrates and phosphates are formed in the deeper layers and are brought to the surface by currents This dependence of the phytoplankton (and of course ultimately all the plankton, great and small) on currents leads to considerable space being devoted to water movements The understanding of these movements is facilitated by a number of clear diagrams A short account is given of the recent work of Bjerknes and Sandström on the mathematical treatment of currents Chapter iv deals with the gain and loss of heat by the water and with the currents, which are largely responsible for the vagaries of temperature that are found in many places The study of the distribution of temperature with depth shows that in summer a layer of warmer water from 10 to 50 metres in depth overlies a layer of colder water, there being a difference of temperature of several degrees between the two This condition, which occurs regularly in the summer in lakes in temperate regions, has only recently been noticed in the sea, although many of the old temperature records show it quite clearly The difference in density between the two layers prevents them mixing freely, and so prevents the phosphates and nitrates formed in the deeper water from reaching the surface where they can be utilised by the plants A prolonged period of fine weather in summer may therefore cut off the food supply of the phytoplankton

Chapter v deals with the colour and the penetration of light into sea water There is here a considerable field for experimental work, apart from that on photosynthesis, on the effects on marine organisms of light of different wave lengths Chapter vi concludes with a brief review of factors influencing the fertility of the sea and its fluctuations Here we are no nearer the solution than we are to solving the problem of the fertility of the soil, and one of the greatest difficulties in the way is that we know so little of bacterial activity

The author has succeeded in presenting the reader with a clear review of the present position of the study of the physical environment in which marine organisms live There is a list of references to recent literature at the end of each chapter, which adds to the value of the book It can be recommended to all who are interested in the sea, and particularly to those who are studying the physiology of its inhabitants

Our Bookshelf

Lehrbuch der Experimentalzoologie Experimentelle Entwicklungslehre der Tiere Von Prof Dr Bernhard Dürken Zweite Auflage Teil 1 Pp 320 Teil 2 (Schluss) Pp xii + 321 782 (Berlin Gebrüder Borntraeger, 1928) 51 gold marks

IN his first few pages the author of this book defines very accurately the scope of the subject with which he deals It is to include all branches of the analytical study of development in the animal organism considered as a whole, but not that of its parts considered separately In the book he therefore discusses heredity, fertilisation, and the differentiation of specific form He does not deal with the growth of the body in size Having so defined his subject, he proceeds to name it " Experimental Zoology " The use of this title is open to objection from many points of view In the first place, it is not descriptive The experimental method is now used, or is coming to be used, in all branches of the science, wherever its use is effective Its use is certainly as characteristic of many other branches as it is of the subject of this book But a more important objection is that a classification of a science by the methods used in its various branches must always be unsound In zoology this type of classification has been widely used and owes its origin to the history of the science To speak of experimental zoology to day in the sense of the author of this book, or in any similar sense, is an anachronism It would surely be better to allow the term to fall into disuse and to name all the sub divisions of the science according to the subject matter of each It would not be difficult to choose such a title for the subject of this book

Probably the chapters which deal with the experimental study of differentiation will be of most use to biologists outside Germany This is a subject which German biologists have made particularly their own, and a good summary of their recent work upon it was needed This need the book seems to supply The other parts of the subject have been more frequently summarised, and the account given here is often short and sometimes incomplete In particular, only some of the aspects of fertilisation are discussed, and a theory is put forward in regard to it with which by no means all workers upon the subject will agree

It is perhaps not surprising that the examples

quoted are largely results obtained by German workers Numerous examples could be given in which work of apparently equal or greater importance by other biologists is not discussed In other respects the second edition of the book appears to have been brought up to date It should be useful to biologists in Great Britain

A Laboratory Manual of Elementary Physical Chemistry By Prof Edward Mack, Jr, and Prof Wesley G France Pp xi+195 (New York D Van Nostrand Co, London Macmillan and Co, Ltd, 1928) 8s 6d net

THE laboratory manual of Profs Mack and France begins with three theoretical "Exercises", dealing with units and dimensions, significant figures, and errors of experiment, respectively These are followed by a series of thirty five experiments, of which two are concerned with determinations of molecular weights in solution, two more with conductivities and transport numbers, two with the preparation of a standard cell and the study of a concentration cell, whilst the hydrogen electrode and indicators form the subject of two more experiments in the electrical section of the book These experiments provide adequate samples of measurements of those properties of dilute solutions of electrolytes which have occupied such a prominent position in physico chemical literature during the past forty years, but they leave room for an exceptionally large proportion of experiments with gases and liquids other than dilute solutions

The course is therefore exceptionally well balanced, and can be recommended on account of its progressive outlook The text dealing with the individual experiments is well written, and is presented in an attractive form The manual is a competent and trustworthy guide for a laboratory course of thirty six periods, and would serve as a good preparation for more advanced work in physical chemistry

The Year Book of the Scientific and Learned Societies of Great Britain and Ireland a Record of Work done in Science, Literature, and Art during the Session 1927–1928 by numerous Societies and Government Institutions Compiled from Official Sources Forty-fifth Annual Issue Pp vii+420 (London Charles Griffin and Co, Ltd, 1929) 18s net

A NOTE of warning is sounded in the preface to the new issue of this valuable annual The publishers state that for some years past "the heavy cost of production has been altogether out of proportion to the sales", and that although they are anxious to continue their part, they cannot do so without more support

As usual, the societies included are grouped in fourteen sections according to the subject of their activities Societies with London headquarters come first, followed by provincial, Scottish, and Irish societies In each case the address, officers, and particulars of meetings, membership, and publications are given, followed by a list of papers read during the session 1927–28 Incidentally, it is remarked that in future, only papers which are published are to be included, so that the Year Book will be an index of published work, and as such alone the volume must be of considerable service Government departments such as the National Physical Laboratory are included in their appropriate sections

The thanks of scientific workers generally are due to the officials of the societies who have co operated with the publishers in making the Year-Book not only available but also authoritative We hope with the publishers that sufficient sales will be forthcoming to make possible the continuance of this useful reference book

Preparation of Scientific and Technical Papers By Prof Sam F Trelease and Emma Sarepta Yule Pp 117 (London Baillière, Tindall and Cox, 1927) 7s net

IF every beginner, and some experienced transgressors, were to digest the contents of this little book before again attempting to place on printed record the method and results of a scientific investigation, critics of the quality of such contributions to literature would in large measure be deprived of illustrative material, of which there is at present no lack Indeed, had the advice which the authors offer been less well founded, and their specific directions less generally acceptable than is in fact the case, they would still have rendered notable service in emphasising the importance in such matters of clear and logical presentation, of attention to detail, and of a reasonable measure of uniformity Thus, whilst there may be two opinions concerning some of the individual instructions, there can be one only concerning the value of the book as a whole The subject matter deals concisely with the arrangement of a paper and its preparation for the press, and the attention which is afterwards required of the author, it includes a description of methods of citation, abbreviation, tabulation, and illustration Editors and readers of scientific literature will agree that there was room—on many a shelf—for such a book A A E

A Classbook of Practical Chemistry First Year By J Morris Pp viii+103 (London Methuen and Co, Ltd, 1928) 2s

THIS book is intended for pupils commencing the study of chemistry A new feature is that the directions for carrying out experiments are given on the left hand pages, while the results are described on the right hand pages, and the author suggests that "by the adoption of some simple method of covering, the right hand page is completely hidden during practical work" The success of such a scheme must depend largely upon the teacher and upon the age of the pupils The instructions for carrying out experiments are simple and clear, but the scope of the book might with advantage have been slightly extended to include such experiments as the preparation of hydrogen and nitrous oxide The melting and boiling points of sulphur are given as 115° C and 448° C instead of 112 8° C and 444° C respectively The equation for the reaction of magnesium with carbon dioxide (p 39) is incorrect

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

Ozone Absorption during Long Arctic Night

IN NATURE of April 27, p 644, Prof R W Wood again raises the hopes of astronomers that it may be possible to obtain an extension of the ultra violet spectra of the sun or stars by going to a station near the pole at the end of the winter He assumes—as most people have done—that the ozone in the atmosphere is formed by ultra violet radiation from the sun, and since it is the absorption by ozone which causes the abrupt extinction of stellar spectra at about 3000 A , he naturally concludes that this absorption would be least where the upper atmosphere has had least sunlight

I fear that it is necessary to dash any such hopes of astronomers, and possibly this note may save someone from the discomforts involved in a fruitless expedition to high latitudes in the winter We have now, by the kindness of a number of helpers, a series of observations extending over many months at twelve stations, ranging in latitude from 70° N to 45° S These observations are quite regular and consistent, and show that the lowest ozone values are found in tropical regions at any time of the year, while the highest ozone values are found in high latitudes in spring In the tropics there is practically no annual variation, but in high latitudes the annual variation is very large (the maximum amount of ozone is about twice the minimum amount), the maximum being in spring and the minimum being in autumn The autumn values in high latitudes are nearly as low as those in the tropics, so that while in the spring hemisphere the amount of ozone increases rapidly from the tropics to the pole, in the autumn hemisphere the amount of ozone is nearly constant at all latitudes

These results are, of course quite inconsistent with the suggestion that the ozone is formed by ultra violet radiation from the sun The shortest wave lengths from the sun will undoubtedly form ozone, but the longer waves which are strongly absorbed by ozone will decompose it As there is so much more energy in the band of longer wave length, it is not surprising that the equilibrium amount of ozone, when the atmosphere is subjected to both wave lengths, should be very small What forms the ozone is not, at present, certain, but the connexion found between the amount of ozone and magnetic disturbance might suggest some action associated with the aurora, though occurring lower down (the ozone appears to be at a height of about 40 to 50 km , while the minimum height of the visible aurora is about 90 km) Whatever the action forming ozone, it is clear that the equilibrium amount due to sunlight is always smaller than the amount actually present, so that the sunlight *tends to reduce* this amount

If astronomers wish to get spectra extending as far as possible into the ultra violet, they should go to the tropics, or should choose days in temperate regions during the autumn with anticyclonic conditions and a tropical air current above, as under these conditions the amount of ozone is as low in temperate regions as in the tropics

G M B DOBSON

Boars' Hill, Oxford, April 27

Thyroid and Temperature in Cold-blooded Vertebrates

THE thyroid is well known to be concerned with temperature regulation in homothermic animals It seems, however, also to have a somewhat analogous function in cold blooded forms In an experiment undertaken to investigate the temperature coefficient of metamorphosis, a number of sets of half grown *Rana temporaria* tadpoles, after all being exposed to the same concentration of filtered thyroid suspension in water for the same length of time, were placed at various temperatures from 3° to 30° C The thyroid dosage was moderate, sufficient to produce metamorphosis in about a week at room temperature

As expected, temperature exerted a marked effect on metamorphic rate Those exposed to temperatures below 5° C , however, provided a surprise After showing a certain degree of change, they proceeded no further in metamorphosis Even when removed to room temperature, they continued indefinitely in this half and half condition, as shown in the photograph (Fig 1), taken several weeks after removal

That permanent intermediate conditions between larva and adult could be obtained in urodeles was already known from the work of Jensen and others on axolotls This is, I believe, the first case in Anura It confirms the view that metamorphosis is not an all or nothing reaction The relation to temperature, however, is what especially concerns us here The half and half state can only be interpreted as follows (1) the treatment with thyroid *ab extra* causes a marked compensatory reduction in the animal's own thyroid (a fact well known in amphibian experiments), (2) some of the effect of the thyroid dose, which causes rapid metamorphosis at higher temperatures, is here used up in counteracting the effect of low temperature instead of in producing metamorphosis

FIG 1

Something of the same sort can be deduced from other work, such as that of Adler, who found that in untreated tadpoles high temperature caused regression of the thyroid, low temperature hypertrophy, both in growth and functional activity

The conclusion appears to be justified that in tadpoles the thyroid is acting as a primitive temperature regulator, or rather as a *temperature buffer* The metabolism of tadpoles is lower in the cold than in the hot , but thanks to the thyroid's hypertrophy in the cold and regression in the hot, and to the fact that thyroid secretion increases metabolism, the difference is not so great as it would be without a thyroid On this view, the temperature coefficient of oxygen consumption and other metabolic activities should be greater in thyroidless than in normal tadpoles It would be of great interest for anyone who has command of the technique of thyroidectomy in frog embryos to put this deduction to the test

JULIAN S HUXLEY

King's College, London, W C 2

Mimicry

IN NATURE of April 27 there appears an article on mimicry by Dr Hale Carpenter, of Uganda, in which he pays me the compliment of quoting extensively from an essay of mine on evolution which appeared in the volume "Evolution in the Light of Modern Knowledge" In Dr Carpenter's article he asserts

that 'natural selection' affords the only satisfactory explanation of mimicry, and he criticises the tentative explanation which I put forward

I quite freely admit that I am unable to give an explanation of the numerous facts adduced by Dr Carpenter To do so would require years of original work in each locality, the environment, both physical and biological, would have to be thoroughly analysed in each case, which notoriously has not been done We should have to account for the fact that in some cases the supposed model is rare and the mimic far more numerous, and we should have to deal with the distressing circumstance that evidence for serious attack by birds on butterflies in the adult condition is sadly lacking Bergh in his "Nomogenesis' states that only one example of this was known to him, and that was in Ceylon, where the bee eaters (Meropidæ) devour large numbers of the supposedly distasteful Danaidæ '

Of one thing, however, I am certain, and that is that natural selection' affords no explanation of mimicry or of any other form of evolution It means nothing more than 'the survivors survive' Why do certain individuals survive? Because they are the fittest How do we know that they are the fittest? Because they survive Is not this a mere form of words, just as deserving of condemnation as the phrase 'the Will of God' used by Darwin s theological opponents?

That more young are born than can survive was known to Lamarck, and is explicitly set forth in his 'Zoological Philosophy, but he did not make the mistake of supposing that the killing of James can affect the qualities of Tom Put in other words, natural selection can only 'select' what is already there, and the real problem for science is how what is there came into existence Towards the solution of this problem, so far as it affects the wing colours of butterflies, very little has as yet been done, nevertheless, a beginning has been made Sir Frederick Gowland Hopkins has shown that uric acid forms the white background in the wings of Pieridæ, and my friend, Dr D L Thomson, now lecturer on bio chemistry in McGill University, Montreal, has shown that in another family the colour of the background is due to a substance in the plant on which the larva feeds Only along such lines as these will the problem of animal coloration be solved

When the school to which Dr Carpenter apparently belongs are asked how the variations which are 'selected' originate, their only answer is chance, and 'chance' as an explanation of a regularly recurring biological phenomenon does not commend itself to me E W MACBRIDE

Imperial College of Science,
South Kensington, S W 7

DR HALE CARPENTER in his article on mimicry (NATURE, April 27) mentions that it is held by many as an objection to the theory of the evolution of mimetic forms by natural selection that the mimic must be mistaken by the predatory animal for its model, if the resemblance is to be of any use to it, and that therefore slight resemblances will be useless, and the evolution of the perfected resemblance unintelligible This difficulty, he suggests, may be removed by the consideration that the mimic need only *remind* the enemy of its model to set up a repulsion in its mind and so escape He instances our repulsion to a worm, which he attributes to its resemblance in form to a snake, for which we have an ancestral repulsion

Is this necessary? Does not the objection in any case rest upon far too anthropomorphic a conception of the animal mind? Psychologists tell us that the animal may be regarded for practical purposes as unreasoning in everyday life If this is so, the mental processes of an animal such as a bird in searching for its prey will be very different from ours in looking for an object We, as we examine the bark of a tree for an insect, are continually comparing the form of each piece of bark with that of the insect, and considering whether it is bark or insect The bird will not consider, its glance will pass over the bark, often slowly and with *apparent* care, until some object, by its resemblance to the remembered picture of the insect, starts the feeding reaction There is no conscious comparison, the stimulus is received and the reaction follows instinctively To protect the insect, its resemblance to the bark need only be sufficient to keep the stimulus, when the bird's glance lights upon it, below the threshold value for the reaction

Protective resemblance and mimicry are here entirely parallel The probability of stirring up the feeding reaction will be less the more perfect is the resemblance either to an inedible animal or to an inanimate object, but it seems that a very slight resemblance may often be effective We know how readily we may mistake objects at a first glance, especially when our minds are inactive, for others to which they have only a slight resemblance A man, waking from sleep, may mistake clothes thrown over a chair for a person in his bedroom A second glance, always accompanied by thought and comparison, shows him his mistake, but for the animal there is no such thought and comparison Hudson ('Birds and Man, Dent, 1923, pp 46 8) has an account of an incident in which he was mobbed at dusk by a flock of goldcrests, and later by another of swallows and house martins in full daylight The behaviour of birds was due, as he afterwards showed, to the resemblance of the colour of his cap to that of the fur of a cat The acuteness of the vision of the predatory animal only enters indirectly into the problem The bird's vision may be easily acute enough to distinguish the differences between the mimic and its model, just as the swallows could certainly have appreciated the difference in form between the cap and the cat Yet the differences may be unperceived and the resemblance effective, even when it is slight These considerations seem to remove the difficulty, felt by many, in the evolution of mimicry and protective resemblance from beginnings which must have been very imperfect G S CARTER

Anomalous After-Effect with Quartz

THE true and the apparent resistivities of some dielectrics have been found by S W Richardson (*Proc Roy Soc*, A, **92**, 1916, **107**, 1925), one of the writers (the paper is now in the press at the Tôhoku Imperial University), and others The apparent resistivity of quartz under a certain constant applied potential increases rapidly with time and then gradually tends to a saturation value after about 30 minutes for quartz plate cut perpendicular to its optical axis (The resistivity is measured by conducting charge through dielectrics under various applied potentials, and the time means the duration of the application of a constant potential)

It may be expected from the paper of one of the writers (*Sci Rep Tôhoku Imper Univer*, **10**, 101, 1921) that the apparent resistivity will show some anomaly for applied potential which increases beyond the 'limit potential' Thus, we found an anomalous after

effect on the apparent resistivity of quartz plate cut perpendicular to its optical axis First, we put a known potential on the quartz during a constant time interval (always 10 minutes), in this time interval the quartz is made to conduct the electric charge freely, and it is connected to earth during a known time interval, then putting on a known potential, the accumulated charge due to conduction is measured during a known time interval, in this case the apparent resistivity is much smaller than that of the quartz in neutral state Next, it is earthed until the residual charge and the time effect due to the latter potential have completely disappeared, and then the measurement of the apparent resistivity is made under the same external conditions as the above during a known time interval, and then it is earthed in this case the apparent resistivity is a little larger than that of the first, but yet smaller than that of neutral state

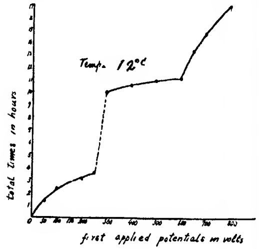

FIG 1

The measurement and earthing as above are repeated until the effect of the first applied potential disappears The variation of this total time interval for the first applied potential which affects the apparent resistivity as an after effect is given in Fig 1 The potential for measuring the apparent resistivity is always 50 volts The temperature of the quartz is always kept at 12° C As shown in Fig 1, the time interval during which the after effect exists increases slightly with the potential and is discontinuously increased at the potential between 300 350 volts per mm thickness (250 300 volts for actual thickness), and again slowly increases, and from about 700 volts per mm thickness (600 volts for actual thickness) it increases rapidly, and it seems that it gradually tends to a saturated state In the paper of one of the writers above referred to, the limit potential is most important for dielectrics, and for quartz is equal to 324 volts per mm thickness as the mean value from the residual charge and time effect Thus it can be concluded that the anomalous after effect appears at the limit potential

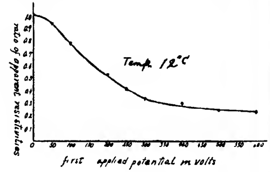

FIG 2

Fig 2 shows the variation of the ratio of the apparent resistivities at 5 minutes after the first earthing and the neutral state, with respect to the first applied potentials, the rate of decrease of the apparent resistivity increases rapidly in the neighbourhood of the limit potential and then gradually tends to a saturation value

The decrease of the apparent resistivity and the appearance of the anomaly are exactly the same in both cases, the first applied potentials are positive and negative, and the after effect depends simply on the absolute value of the first applied potentials Hence it seems to us that this anomalous after effect is probably due to some property of the atomic lattice of quartz

Plasticity and Water Absorption of Clays

IN spite of the cause of the plasticity of clays having been the subject of much speculation, no generally accepted theory appears to have been developed The following measurements of water absorption and some other properties of clays throw further light on the problem and appear to me to be of general interest in the theory of the properties of colloids

The 'water absorbed' was measured by determining the increase in concentration in chloride ions which occurred when the clay, dried at 100°, was added to a standard solution of the chloride of the base with which the clay was saturated, it having been proved by various workers that clay does not absorb the chlorine ion Five grams of clay were usually added to 10 c c of solution, after centrifuging, the weighed decanted liquid was titrated with silver nitrate solution This method of 'negative absorption' seems to have been strangely neglected in the study of the water affinity of colloids in spite of its use by McBain in the study of soaps, and by Gaunt and Francis for silica, and ferric, and aluminium hydroxide gels (*Trans Faraday Society*, **24**, 32, 1928) The other three properties tabulated were determined on the soil which contained 60 per cent of clay. The relative 'hardness' figures represent the percentage material which failed to be powdered after a standard shaking treatment of dried pellets of each material The Atterberg

TABLE I

CLAY FROM HEAVY COTTON SOIL NO 38724

Base in Clay	Water absorbed from Chloride Solutions per 100 gm of Clay		Plasticity Number	Relative Hardness	Bulk Density
	N	*N*/10			
Li	18 4	46 5	82	92	2 12
Na	12 8	34 4	60	85	2 07
Mg	10 4	17 4	56	82	2 01
Ca	8 3	16 8	42	57	1 80
NH_4	5 2	15 4	22	6	1 70
K	2 7	15 1	22	1	1 45
H		5 3	20	0	1 65

plasticity number represents the range of percentage water content over which the soil remains plastic

This direct demonstration of the lyophilic series correlates nearly perfectly with the other properties tabulated Preliminary counts in an ultra microscope of the number of particles per gram of clay seem to indicate that the ultimate dispersion of these clays will also follow the order of hydration, but it should be emphasised that this is not the same as the order of the flocculating concentrations of the different clays by the chlorides of the respective bases

These figures show clearly how the properties of one clay with different bases follow the water absorption of the clay, Table II shows in a preliminary way how the plasticity of different clays with the same base (sodium) also follows the water absorption The properties of some of these clays have been described by Joseph and Oakley (*Jour Agr Science*, **19**, 121, 1929)

TABLE II

Clay from—	SiO_2/Al_2O_3	Water absorbed from $N/10$ NaCl by 100 gm Clay	Plasticity Number of Soil	Clay (per cent in Soil)
Bentonite	7	41 8	441	91
38724	4 0	31 3	60	62
30100/1	3 7	28 5	56	74
29933/4	2 7	26 6	37	57
13107	2 4	18 5	20	80
Amorphous silica		15 1	about 1	
Kaolin 10096	2 0	3 0	about 1	about 64

Although the clay contents of the soils are not comparable, the influence of the composition and hydration of the clays is still sufficient to determine the plasticity This is particularly striking in the low plasticity of No 13107 This soil contains 80 per cent of a clay which, as shown by the ultra microscope, contains more than twice as many particles as No 38724 It is evident that although the fineness of a clay may be a factor in its plasticity, the water affinity is more important

Finally, the water absorbed by a clay is greatly influenced by the concentration of the reference salt used in the solution This is presumably an osmotic effect Below is shown the effect of different concentrations of sodium chloride on the water absorbed by sodium 'saturated' clay No 38724

Dilution of NaCl (litres)	0 2	1	10	25	50	125
Water absorbed per 100 gm dry clay	6 7	12 8	34 4	49 0	80 0	102

In keeping with this change in absorbed water the plasticity number fell 13 units when normal sodium chloride solution was used instead of pure water Experiments at higher dilutions are rendered difficult by the deflocculation of the clay At present it is impossible to decide whether this phenomenon of water absorption is due to imbibition by hypothetical gels in the clay or to a kind of polar absorption round each clay particle as postulated by Hatschek for other colloids (*Jour Phys Chem*, **31**, 383, 1927) and others (Weisner and Cunningham, *Jour Phys Chem*, **33**, 312, 1929) In view of the increase of dispersion with hydration observed in the ultra microscope and the impossibility of separating a clay into two fractions of markedly different properties, I incline to the latter view

Co-education

IN NATURE of April 13, I note an article which seems to me to maintain the thesis that co education in the medical schools of London is undesirable because its prevalence would interfere with the efficiency and success of the London School of Medicine for Women I would suggest that your brief against co education is carried considerably farther than the highest authorities at the London School of Medicine for Women really desire, if one may judge from a letter to the *Nation and Athenæum*, written by Sir Francis Acland, the chairman of that School, dated April 9 In that letter Sir Francis expresses a pained surprise at my suggestion that the London School of Medicine for Women objects to co education He declares 'All the evidence given by the School before the Committee" (that is, the recent University Committee) "was in favour of co educational facilities, and we have always welcomed every extension of it" The 'quota' system, which is condemned in NATURE, was first suggested by the Professorial Board of University College in 1915, since which date University College Hospital has taken a quota of twelve female students annually, and the system has worked with complete success

You ask why the recent University Committee, appointed on the motion of Mr Walter Spencer and myself, should have declared that there was a "prepossession in favour of co education in the University" The reason is probably to be found in the report of a previous University committee in 1915, which had investigated this very question of medical co education at the men's schools of London That report was overwhelmingly in favour of co education as a principle It is significant that the large majority of women's societies have taken the view that co-education should be practised in the medical schools of the University of London as it is practised in provincial universities

E GRAHAM LITTLE

House of Commons, S W 1, April 18

DR GRAHAM LITTLE is well known as a champion of medical co education, and we print his letter on the subject with pleasure The article in NATURE was not intended to indicate any general objection to co education, but we suggested that the question of medical co education in London constitutes a special problem since a well organised system of unisexual medical schools is already in existence Conditions in 1915 during the War were quite exceptional, and the view then taken on the question of medical co education cannot be regarded as binding the University We retain our dislike of the 'quota' system, notwithstanding Dr Graham Little's interesting evidence as to its origin and working

THE EDITOR

Active Nitrogen

THE recent analysis of the band spectrum of nitrogen in the Schumann region by Profs R T Birge and J J Hopfield (*Astro Jour*, **68**, p 274, 1928) throws a flood of light on the identity of active nitrogen It has been shown that the bands in the Schumann region have nothing in common with the bands in the visible and the ultra violet The presence of a strong metastable level in the N_2 molecule has thus been established, and is in accord with the electronic level scheme of R S Mulliken (*Phys Rev*, **32**, p 216, 1928)

That active nitrogen is a molecule of nitrogen in this metastable condition is further supported by some recent experiments which we have carried out on the life of active nitrogen. This can be varied within wide and indefinite limits simply by the regulation of pressure, everything else remaining constant For a short life of the order of 0 1 sec the experiment is best performed by drawing our nitrogen at about 7 to 8 mm pressure from a region of condensed discharge For very low pressures, say 0 03 mm of mercury, the active nitrogen is formed with an electrodeless discharge and its life may be abnormally extended to several minutes It has been clearly observed by us that for any given specimen of nitrogen the life of active nitrogen increases continuously and regularly with the decrease of pressure This is a strong evidence for the presence of metastable molecules

In another series of experiments we have produced the infra red lines of nitrogen belonging to the electronic configurations $2L_1M_1 \longleftarrow 2L_2M_2$ by exciting first nitrogen and then active nitrogen with uncondensed discharge under exactly identical conditions No change in the relative intensity of lines was observed, which points to the conclusion that there is no appreciable density of atoms present in active nitrogen

P K KICHLU
S BASU

Department of Physics,
Science College, Patna, Mar 27

DR KICHLU and Mr Basu seem to have overlooked an early investigation (*Proc Roy Soc*, A, vol 86, p 264), in which it is shown that a given sample of active nitrogen, made active at a low density by the electrodeless discharge, can, after intervals up to several minutes, be made momentarily very bright by compression

This experiment seems to cover what Dr Kichlu and Mr Basu have observed, with the additional point that compression causes the active gas to give up its energy rapidly *in the form of light* (α bands)

This seems clearly to prove that collisions of some kind are the occasion of the emission of α bands (1st positive nitrogen bands)

I am not sure if I understand the views of the authors rightly But the level which Mulliken concludes is metastable is the lower level concerned in the emission of the α bands It is not clear to me how the metastability of this level helps us to understand how the gas remains for a long time loaded with the energy necessary for the emission of α bands, which involve a level several volts higher

Terling Place,
Chelmsford, Essex, April 24

Properties of the Terms of the Helium Molecule

IF in a diatomic molecule the influence of the internuclear axis on the valence electron is strong compared with the influence of the nuclear rotation (case I), the component σ, along that axis of the vector l representing the moment of momentum of the electron, is, as was shown by Hund, a whole multiple of $h/2\pi$, and the rotational energy is, apart from a constant, proportional to $j(j+1)$ (j = total moment of momentum of the molecule) If, on the other hand, the influence of the rotation is predominant (case II), l is quantised with respect to the axis of rotation, and if its component along this axis is ρ, the rotational energy is proportional to $(j-\rho)(j-\rho+1)$ The energy in the intermediate case is a complicated function of j, and has been calculated approximately for simple cases by Hill and van Vleck (*Phys Rev*, **32**, p 250, 1928)

Case I is realised in most molecules The electronic spin usually complicates the problem In the helium band spectrum we can observe, as already shown in a qualitative way by Weizel (*Zeit f Phys*, **52**, p 175, 1928), all the different stages of transition between the cases I and II The terms which are produced by the different orientations of orbits with $l = 2$ (δ complex) are of special interest The bands which originate from a combination of this complex with the $2p$ level show a very anomalous behaviour both with respect to the position of the lines and to their intensities All their properties can, however, be understood, if one follows the transition from case I to case II The connexion between the theoretical and empirical term symbols and the values of σ and ρ is given below

Term	Case I	$\pi\Sigma_b$	$\pi\Pi_a$	$\pi\Pi_b$	$\delta\Sigma_a$	$\delta\Pi_b$	$\delta\Pi_a$	$\delta\Delta_b$	$\delta\Delta_a$
	Case II	π_1	π_0	π_{-1}	δ_2	δ_1	δ_0	δ_{-1}	δ_{-2}
Empirical designation			p_a	p_b	z	x	y	d_b	d_a
σ		0	1	1	0	1	1	2	2
ρ		1	0	−1	2	1	0	−1	−2

The connexion of the Greek letters used in designating the terms with the values of l and σ is evident (Mulliken uses S, P, D instead of Σ, Π, Δ) In the He_2 molecule only the terms which are antisymmetric in the nuclei are present They can only have odd values of $j-\rho$ Therefore, also in case I, j is odd for even values of ρ (index a) and even for odd ρ (index b)

In the 3δ complex, case I is realised for small values of j This means we must use the σ classification and have the normal type of transitions studied especially by Mulliken We have here $\Sigma \dashrightarrow \Pi$, P, Q, and R branches, $\Pi \longrightarrow \Pi$ only P and R branches, and $\Delta \dashrightarrow \Pi$, P, Q, and R branches That is in exact agreement with the observations For larger values of j the coupling of l with the internuclear axis becomes looser, which is shown by a shift in the energy levels and the appearance of Q branches in the $\Pi \longrightarrow \Pi$ band At the same time the P branch of the $\Sigma \dashrightarrow \Pi$ band disappears and the Q branch becomes much weaker The behaviour of the separate energy levels is represented by formulæ obtained in the same way as those of Hill and van Vleck

The $2p$ 4δ complex, which is also completely known, shows that the 4δ terms are also for small values of j in the transition stage between cases I and II Whereas the energy of the separate terms becomes a complicated function of j, the theory shows that the mean values of δ_1 and δ_{-1} and those of δ_2, δ_0, and δ_{-2} behave like the energy of a $\sigma\Sigma$ term which can always be represented by a simple quadratic expression in j That is in excellent agreement with the observations, and the molecular constants can easily be calculated in this way

For the 5δ and 6δ complexes the observational data are not yet entirely complete But the existing data show that stage II is reached already for very small values of j The anomalous energy values have disappeared The nuclear moment of momentum is again an integration constant and ought therefore only to change 0 and ± 1 in a transition That means that for the combination of a δ_ρ term with the $2p$ level which is in stage I, we get the following branches:

Initial term	δ_2	δ_1	δ_0	δ_{-1}	δ_{-2}
Branches	R	R, Q	R, Q, P	Q, P	P
Appearance	P	Q, P	R, Q, P	R, Q	R

So far as the data permit this to be tested, it was found to be in agreement with the facts

The transition stage of the π-terms is analogous, though much simpler, owing to the fact that there are only three of them, and because the one with $\sigma = 1$

and $\rho = 0$ ($\pi \Pi_e$, the term which gives the Q branches in the $s \to p$ bands) behaves like a $\sigma\Sigma$ term

The constants $B = \frac{h}{8\pi^2 I}$ and A, which expresses the degree of coupling of the vector l to the internuclear axis, for the most important terms are

	2π	3π	4π	3δ	4δ	Par 3δ
A	8890	2971	1482	165	75 06	132
B	7 336	7 173	7 130	7 072	7 088	7 079

For the degree of accuracy, way of calculating, etc, I must refer to the full paper which will be published elsewhere and will contain all the details The ideas expressed in the present note have also proved fruitful for the understanding of the spectrum of the hydrogen molecule

Elastic Collisions of Electrons with Helium

IN view of the recent experiments of Dymond and Watson on the scattering of electrons in helium (*Proc Roy Soc*, vol 122, p 571), it has been of interest to work out the scattering predicted by the wave mechanics The method used is that of Born (*Gottinger Nachrichten* p 146, 1926) and involves two separate approximations In the first place, we neglect the polarisation of the atom by the incident

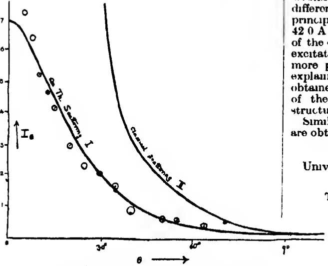

FIG 1 —Elastic scattering of 210-volt electrons by helium Experimental readings fitted at 30° are indicated by ○

electron, the atom being treated as an electrostatic centre of force We have used the field calculated for helium by Hartree (*Proc Camb Phil Soc*, vol 24, p 111) Secondly, we have calculated only the first approximation of Born, which is sufficient only if the de Broglie wave length of the incident electrons is large compared to the classical distance of closest approach Neither approximation will introduce a serious error if the energy of the incident electrons is large compared to the ionisation energy of the atom For 200 volt electrons the error should not be greater than about 20 per cent

Fig 1 shows the variation of scattering with angle to be expected for elastic collisions with 210 volt electrons I_θ is the scattering per unit solid angle Curve I gives the quantum theory scattering, and curve II the classical scattering by the Hartree field of the atom The two curves lie close together for large angles, where the scattering is mainly nuclear For small angles there is a marked difference the classical I_θ becoming infinite for θ equal to zero, as the following table suggests

θ	3 3°	5 7°	19°	30°	44
I_θ (classical)	190	54	2 1	0 81	0 26

It is not true, as is often stated, that the scattering integrated over all angles is the same both classically and on the quantum theory

The results of Dymond give relative scattering only, and we have therefore fitted our curve and his readings at 30° Considering the approximate nature of our calculations, the agreement is as good as can be expected It is obvious that the experimental readings could not be fitted to the classical theory curve

An account of these calculations will be published shortly, in which it is hoped to consider also inelastic collisions

Densitometric Measurements of the K-α Line of Carbon

(BY CABLE)

DENSITOMETRIC measurements of the $K\alpha$ line of carbon in three orders obtained with a grating having twelve hundred lines per millimetre show distinct, clearly measurable separation of components in the second and third orders, wave lengths checking in different orders and on different plates There are four principal components in the main line at 44 2 A, 42 0 A, 45 4 A, and 46 15 A The relative intensities of the components apparently depend on conditions of excitation, some of the longer components becoming more prominent at higher driving potentials, thus explaining the divergence of wave length values obtained by other observers in the third order Some of these components apparently have a doublet structure

Similar but broad and more complex separations are obtained in boron $K\alpha$

The Assembling of Male Moths due to the Sense of Smell

DR ERNEST WARREN, in his interesting letter published in NATURE of Feb 23 (p 278), suggests that the assembling of male moths around the female is evidence for the existence of "recondite influences"

It is, however, clear that the flight of the males is stimulated and directed by air borne odoriferous particles, which, however have no effect upon the human olfactory sense If a virgin female of certain moths, such as the Oak Egger, be carried in a closed box, males are not attracted, but they begin to assemble directly the cover is taken off Furthermore, the box itself may continue to attract for some days after the female has been removed Porous substances continue to be attractive longer than dense ones Such 'assembling' males possess wide spreading antennæ, adapted to comb the air during their rapid, characteristic flight, which is such as to test a large cross section as they proceed Some of the detailed evidence that the attraction is due to scent has been brought together in the *Proceedings of the Entomological Society of London*, vol ii 1927–28, pp 75 82

EDWARD B POULTON

Physics in Relation to Oil Finding[1]

By Prof A O RANKINE

IF a time graph is plotted, with the intervals between the instant of explosion and that of *initial* disturbance of the seismograph as ordinates, and the distances between explosion and seismograph

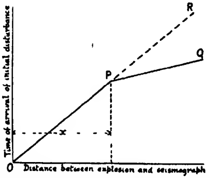

FIG 2 —Time distance graph corresponding to Fig 1 x is the distance at which direct and indirect disturbances arrive synchronously

as abscissæ as in Fig 2, it will display a break (at P) where the times of arrival of direct and indirect disturbances are equal Actually the distance x for time equality is related to the depth of the interface by the relation

$$\frac{h}{x}=\frac{1-\sin\theta_e}{2\cos\theta_e}$$

Moreover, the slope of OP, which corresponds to the direct disturbance, is proportional to $1/V_1$, while the slope PQ, which relates to the indirect disturbance, is proportional to $1/V_2$ Thus $\sin\theta_e = V_1/V_2 =$ (slope of PQ)/(slope of OP) Hence θ_e is determined, and its insertion in the above equation, together with the value of x read from the graph, enables the depth h of the interface to be calculated

Owing to its relatively large magnitude, it is possible to recognise on the seismograms the arrival of the direct disturbance even when it reaches the seismograph *after* the indirect disturbance This corresponds to the dotted portion PR of the curve, or OP produced

This simple case is merely an illustration Many others have been worked out, such as those corresponding to more than one stratum, sloping strata, or interfaces which abruptly change depth To deal with these here would lead us too far In all cases the procedure has to be the assumption of various possible underground structures until one is found which by calculation agrees with the time graphs actually obtained For this purpose it is frequently necessary to multiply observations by changing the position of the explosion point and the direction of the line of observation The accumulation of field data over various structures also obviously facilitates the recognition of similar structures in subsequent surveys

It is only possible to deal very briefly with field procedure Where, as often happens, the salt-domes or limestone anticlines are deeply buried, large charges must be exploded because of the long ranges which must be covered to reach and pass beyond the point of time equality—an essential condition if the depth is to be determined Consequently it is economical to multiply the number of seismographs used rather than the explosions For celerity of survey the seismographs must be readily portable and easily set up in their new positions In the early days of this work the instant of explosion (necessary for the calculations) was deduced from the position of the air borne

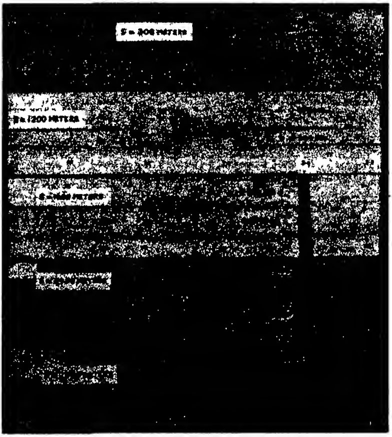

FIG 3 —Five seismograms obtained on an observation line over a salt dome Dots at bottom of each are made by time marker, interval being $\frac{1}{10}$ second

[1] Continued from p 686

disturbance on the seismogram, assuming the value of the velocity of sound in air This in practice is often the largest effect recorded, but it arrives much later than the earth borne vibrations This method, which is rather inaccurate on account of the wind and temperature corrections, has now been superseded by including with the recorder an oscillograph which places on the record a wireless signal actuated by the breaking of an electric circuit by the explosion itself The recorder includes a time marker which enables the transmission times to be estimated with sufficient accuracy Photographic recording is ordinarily used I have seen a troop of observers of the Geophysical Company, Ltd, operating this system in the Anglo Persian oil fields, and have nothing but admiration for the celerity and efficiency with which the field work is carried out

Through the courtesy of the Geophysical Company, Ltd, it is possible now to publish for the first time a group of five seismograms obtained with Mintrop seismographs (which record vertical movements of the earth's surface) over a salt dome These are shown in Fig 3, and exhibit the various effects to which reference has been already made Each shows (at the point O) the wireless signal of the explosion, and the final effect of the air borne wave, in some cases so large as to make the detail

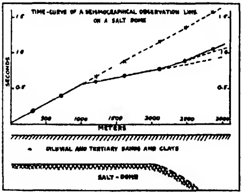

Fig 4 —Time-distance graph corresponding to seismograms in Fig 3

of the trace invisible In the last three records a piece has been cut out so as to bring this effect within the scope of the diagram The earth-borne disturbance, which lies between the wireless signal and the air wave, changes in type as the distance is increased. The indirect disturbance, which is not visible in the first seismogram at 308 m, makes its first appearance in the second at 1200 m, as a small vibration preceding the much larger direct disturbance In the next two, at 1600 m and 2450 m, the time interval between the indirect and direct disturbance has increased progressively in magnitude, while in the last, at 2850 m, the time difference is approximately the same as in the one just previous

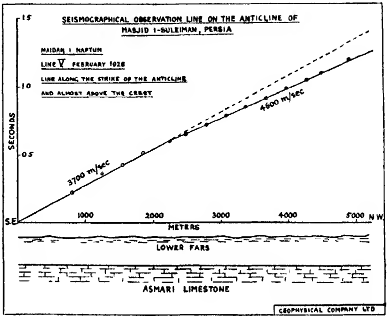

Fig 5

The time graph in Fig 4, which includes points from other seismograms besides those shown in Fig 3, exhibits the results graphically It shows unmistakably, at a range of about 1000 metres, a discontinuity of the kind mentioned in an earlier paragraph, and the two different slopes before and after this point There is displayed besides the ultimate tendency of the curve to resume its initial slope—a feature known from theoretical considerations probably to signify a dipping of the interface The depth, and roughly the shape and location of the edge of the salt-dome have thus been deducible, and are shown in the lower part of the diagram

Time graphs of the same general character relating to the great limestone anticline, from which most of the Anglo-Persian oil is at present drawn, are shown in Figs 5 and 6 The survey in this region was carried out for the Anglo-Persian Oil Company, Ltd, by the Geophysical Company, Ltd, and really constituted a test of the efficacy of the seismic method over a region where the general features of the limestone structure were already known as a result of extensive drilling Fig. 5 relates to a direction of observation parallel to the long axis of the anticline and Fig 6 to a traverse across it The conditions were much less favourable than over salt-domes, owing to the depth of the limestone and to the relatively small difference of velocity as between the limestone and the Lower Fars with which it is covered This is indicated in the time graphs by the smallness of the changes of

slope in the curves Nevertheless, the method, which had previously been applied extensively and successfully to the location of salt domes in Texas, proved of value in Persia also, the limestone depths being measured to an accuracy of 10 to 15 per cent There are, therefore, good grounds for confidence that the surveys being carried out by the Geophysical Company, Ltd, on similar structures of unknown shape in other regions of Persia and in Iraq will provide the data required for successful drilling for oil

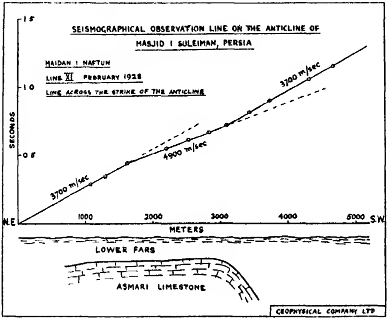

FIG 6

For descriptions of portable seismographs the reader must be referred elsewhere, for example to the recently published translation of Dr Ambronn's book,[8] which contains the original references

[8] *Elements of Geophysics* By Dr Richard Ambronn translated by Margaret C Cobb (London McGraw Hill Publishing Co, Ltd)

Mintrop's seismograph, with which most of the seismic surveying has been done, is one in which the magnification of the earth's movement is secured partly mechanically and partly optically There are others of the same type, notably Schweydar's, which records also horizontal movements Another type employs electrical magnification, as in Dowling's and Ambronn's instruments It is doubtful whether any of them imitates precisely the movements of the earth's surface, but so long as it is merely a question of determining the instant of first arrival of the disturbance, this is of no great importance It is nevertheless worthy of note that the production of an exact recorder will open new lines of attack on the problem, such as the determination of the angles at which the disturbances arrive at the earth's surface

Progress is being made in the gravimetric and seismic methods of survey, both as regards improvements of the instruments themselves and the technique of procedure in the field and in interpretation In this matter Great Britain is much behind-hand, and it is hoped that this article may contribute to the stimulation of that interest which is essential to progress

I desire to express my thanks to the Anglo-Persian Oil Company, Ltd, and to the Geophysical Company, Ltd, for approving and facilitating the publication of this article I am specially indebted in this respect to Prof Mintrop, and to Mr Ernest H Neville and Dr Schmidt of the latter Company

The Centenaries of Davy and Young

IN the National Portrait Gallery hangs the well known composite portrait group of eminent British men of science who were alive in 1807–8, the group being shown assembled in the Library of the Royal Institution There are forty eight portraits in all, including those of Banks, Watt, Rumford, Jenner, Herschel, Cavendish, Telford, Trevithick, Wollaston, Dalton, Davy, and Young The oldest represented in the group was Matthew Boulton, the partner of Watt, who was born in 1728, while the youngest was Davy, born just fifty years later, in December 1778

No more appropriate setting could have been found at that time for such a group, for though at its birth the Royal Institution had for its sponsors many notable men of the day, its infancy had been a somewhat precarious one, and it was mainly through the talents of Davy, then probably at the height of his powers, that it had been rescued from the uncertainties which had threatened its very existence It had been raised to a foremost position among scientific institutions, where not only the learned, but also the fashionable and the great, gathered to see the striking experiments of Davy and to listen to his brilliant discourses from which we are told Coleridge increased his stock of metaphors

Founded in 1799 through the exertions of Rumford, the Royal Institution had already counted among its first professors Garnett and Young, but it was the lectures of Davy which marked the beginning of the popularity it has since enjoyed and the reign of discovery with which its name is linked After Davy came Brande, Faraday, Tyndall, Dewar, and others, and in "Britain's Heritage of Science" we are told "there is no

building in the world associated with so many classical and revolutionising researches as that in which the Royal Institution is housed"

If the setting for this remarkable group invites our approbation, no less does the date of its execution appeal to our sense of historic fitness The early years of the still young century had been full of promise, and though owing to the ambition of Napoleon few nations were free from the threat of war, scientific and industrial development was proceeding apace, and the very names of Cavendish, of Herschel, of Watt and of Trevithick recall the pioneering work and the planting of the seed from which our later harvests have come At home and abroad, science in 1807 was engaging some of the keenest minds The guillotine, it is true, had robbed France of her greatest chemist, but she still counted among her veterans, Laplace and Lagrange, Legendre and Coulomb, while following in their footsteps came Fourier, Biot, Ampère, Malus, Arago, and Fresnel

As in France, so in Europe generally, science and invention were bearing good fruit Astronomy had been enriched by the discovery of Ceres, Pallas, Juno, and Vesta, Volta's great invention of the electric battery was being applied in a hundred experiments, Chladni had made the world his debtor by the publication of his work on acoustics, while Oersted had begun his work at Copenhagen, where he was destined to make his great discovery of electro magnetism To the particular years 1807 and 1808 belong the publication by Thomson of the atomic theory of Dalton, the publication of Young's "Lectures on Natural Philosophy", and the memorable experiments of Davy leading to the isolation of sodium and potassium

However interesting a review of the science of that time may be, our immediate attention is naturally directed to the careers of Davy and Young, both of whom died in May 1829, a hundred years ago, Young passing away on May 10 and Davy on May 29, Young being then but fifty five and Davy only fifty years of age Strangely unlike in temperament, in character, and in their reaction to the buffets and rewards of life, they yet present many interesting parallels as well as contrasts Even Galton would, perhaps, have found it hard to determine the influence of heredity on their careers, for Davy was but the son of a woodcarver of Cornwall, and Young the son of a Quaker landowner of Somerset In neither instance, also, did early training have much to do with their subsequent successes The astonishing precocity of Young was equal to that of a Macaulay or a Rowan Hamilton, and as a boy of fourteen years of age he was acquainted with Latin, Greek, French, Italian, Hebrew, Persian, and Arabic Davy had a mind equally alert and a memory equally tenacious, but he enjoyed fewer advantages than Young, and it was to a Quaker saddler friend and a self appointed guardian that he owed the encouragement and assistance without which, perhaps, his genius might have led him to less congenial pursuits Young was the senior of Davy by five years, and while Davy was serving his apprenticeship to the Penzance apothecary and surgeon, Borlase Young was leisurely following his academic course in medicine at Edinburgh, Göttingen, and Cambridge, where his learning led to his being known as "Phenomenon Young"

It was in 1801 that the paths of these two extraordinary men met, the older one becoming the professor of natural philosophy and the younger the professor of chemistry in the newly founded Royal Institution Davy's first lecture was given on April 25, 1801, Young's first lecture on Jan 20, 1802, but whereas we are told Young found "the number of his attendants diminish daily, and for no other reason than that he adopted too severe and didactic a style", Davy filled the theatre to overflowing, where "his youth, his simplicity, his natural eloquence, his chemical knowledge, his happy illustrations and well conducted experiments excited universal attention and unbounded applause"

Of the details of the work of these illustrious investigators many accounts have been given His experiments with nitrous oxide, his isolation of sodium and potassium and other elements, and his invention of the miner's safety lamp are but a few of the outstanding achievements of Davy, whose name was as familiar in France and Italy as it was in England His invention of the safety lamp he made a free gift of to mankind, and the silver plate presented to him by the colliery owners in recognition of his work was long since sold and used for founding the Davy Medal of the Royal Society Young's work illustrates the versatility of his rare mind His most notable contributions to science were concerned with optics, the strength of materials, and elasticity The first definitions of 'energy' as we understand it and of 'Young's modulus' are to be found in his "Lectures" His views and discoveries in light were fundamental, and he has been called "the founder of physiological optics" Of Young, Helmholtz said 'He was one of the most clear sighted of men who ever lived, but he had the misfortune to be too greatly superior in sagacity to his contemporaries They gazed at him in astonishment, but could not always follow the bold flights of his intellect"

Known widely for their writings, their lectures, their researches, and discoveries, Young and Davy are also remembered for the work they did in connexion with societies, committees, and institutions Both were foreign associates of the Paris Academy of Sciences, both held secretaryships of the Royal Society, of which Davy was the twenty fourth president, while Young was long physician to St George's Hospital The grave of Young is at Farnborough, Kent, that of Davy in a cemetery outside the city of Geneva There is a statue of Davy at Penzance, a marble bust of Young in the Shire Hall, Taunton, while each is commemorated by a memorial tablet on the walls of St Andrew's Chapel, Westminster Abbey Such memorials, however, may crumble and perish, but the work of Young and Davy will endure for ever, for as Davy said when presenting the Copley Medal to Arago "Science, like Nature, to which it belongs, is neither limited by time or space It belongs to the world, and is of no country and no age"

Landscape at the Royal Academy

By Dr VAUGHAN CORNISH

THE representation of the vibrant effect of sheer sunlight is a relatively modern achievement in painting which has, however passed through the experimental stage, and is well given in Mr H H La Thangue's two pictures, Provençal Workers (34) and A Provençal Forecourt (488), and vibrance is well combined with the complementary colouring of sunlight and shadow on the white walls of the Farm near Sospel by Mr St Clair Marston (614) It is, however, from our own Cornish coast that Mr Julius Olsson chooses his examples of moon light on the waters the acme of contrast in tone in an almost monochromatic scene which never fails to touch the chords of emotion The subjects are St Anthony Light (176) and Herring Fleet St Ives (500)

Sunlight and shadow on the waves are rendered in George F Bradshaw's At Sea (1) and on the irregular surface of snow by Donald H Floyd Sunshine after Snow (131) Circumambient colour of sea and sky is effectively accentuated by its concentration and massing on hull and sails in Mr Arthur J W Burgess's Gipsies of the Deep (357) and Pleasure Afloat (281) For the blue depths of atmospheric colour our painters have relied upon the mountain background, as in Lakeside (571) by Sydney V North and in Mr E L Lawrenson's picture of the remote Achill (153) where as in Skye, some peculiarity of insular climate beside the western ocean dyes the distant hills in deepest purple

For catching the moods of the mountains as determined by weather and season, a very mirror of the moods of man, the method of water colour has advantages and the enlarged space now given to the water colours at Burlington House is there fore welcome to the student of Nature, as is also the allotment of a fine spacious gallery to the drawings, engravings, and etchings, among which are many interesting landscapes Mr Alfred Hartley's aquatints, A Storm on the Alps (1082) and Morning Haze on a Swiss Lake (1070), are the reward of those who watch and wait among the mountains In Mr Percival Gaskell's aquatint, On the Lake of Thun (1130), looking west across the water towards the Stockhorn range the suffusion of afternoon light enables the artist to unite the boldness of the peaks and the repose of the lake, the combination which so greatly contributes to the delights of residence in Alpine lakeland In Mr B Eyre Walker's aquatints, October Snow, Winder mere (1126), and the tiny Autumn Snow on Coniston (1156), we are pleasantly reminded of the beautiful aspect of the English Lake District, when the peaks are emphasised by snow caps, while Sir D Y Cameron's wash drawing Cluanie (1034) indicates admirably the way in which the re-entrant line of the lake shore, stronger in tone than the skyline, imparts an appearance of ordered grouping to the surrounding mountains

For landscapes which derive their motive in the cyclopæan masonry of rock structure, we must return to the oil paintings In Pordenick, Land's End, by Charles W S Naper, the strongly jointed rock has a pattern of vertical and horizontal lines so easy for the eye to grasp that the strength of the cliff in no way impairs the sense of repose imparted by the calm sea from which it rises sheer An effect not altogether dissimilar may be seen where church towers rise above the flat expanse of the Fen Country Mr John H Willis's In the Nant Ffrancon Pass (403), one of the few large landscapes, is a fine study of a rhythm of rock structure more exciting to the eye, spiked pyramidal The colouring of this landscape, whether determined by preference or the chances of the season, is not that which best concords with the forms of this district, but we can find satisfaction in Miss Judith Ackland's Snowdon by the Pen y Gwryd Track (647), in which tone and colour convey the solemnity of Snowdonia Other artists seek, I infer, to enhance the abstract quality of strength in mountains by stripping them of atmosphere so that the whole structure, including the serrated skyline in the distance, has a texture comparable to that of a rocky foreground Such appears to be the intention in The Pillars of Heaven (284) and Mountains of Murcia (611) by Mr Guy Kortright, and a somewhat similar treatment is found in The Alps from Sallanches by Mr R M Hughes (160) These studies are in full daylight If it be permitted to a fellow student of mountain beauty, though not a fellow artist, to offer a suggestion, I would venture to cite my experience that in certain types of weather the hours of dawn show the high mountains in a strength of tone rivalling lunar landscapes combined with such conditions of colour as would assist the abstract treatment of massive effect

Among the studies of Arcadian England, there is one of special charm which is likely to escape notice on account of the fact that it is almost the smallest picture in the Exhibition, Miss Dorothy M Snow's water colour, A Sussex Farm (788) It shows that neatness of agricultural landscape which astonishes the visitor from the New World, causing him to exclaim, as I have myself heard, that " this country is a garden " The smoothly rounded lines of the topography of the southern and midland counties of England, and the rounded forms of their spreading, broad leaved trees, make difficult the task of harmonising architecture with the landscape, but in the barren and rocky lands of the Spanish *meseta*, architecture carries the forms of natural landscape to a culmination, as is shown in Mr Oliver Hall's important picture, A Spanish Bridge (86), which gains in effect from its suitable frame of black and gold Among the water colours, Mr Cecil A Hunt's Gorge of the Tagus, Toledo (764), also deals with an architectural culmination of rocky form At the present time, when controversy is so keen on the subject of styles of construction considered in relation to the amenities of the countryside, it is important that we should

No 3106 MAY 11, 1929

The Maintenance of Life and Irritability in Isolated Animal Tissues [1]

By Prof A V Hill, F R S

NOT infrequently one hears the view expressed that physiologists are too ready to work with isolated tissues, not willing enough to study the intact and living animal The isolated organ is said to be abnormal', its behaviour too remote from that of its previous self, in its usual environment, to throw much light upon the normal processes of life There is indeed a danger that those who work under artificially simplified conditions may, in their enthusiasm, extend their results too far the greater danger—I speak with feeling—is that their friends, and the daily Press, may do so for them If you describe how a nerve fibre maintains the electrical potential difference at its boundary by an active process involving the consumption of oxygen, you may find your name in all the newspapers, and be invited to America to raise people from the dead if you prove that chemical disintegration sets in, in a stimulated muscle deprived of oxygen, you may be charged with attempting to create a living cell (and indeed a living 'soul') in the laboratory

Realising this danger, however, appreciating that only after hard and critical thinking may the results of laboratory work under simplified conditions be applied to the graver practical problems of life, we may—in fact, we must—go forward in the confident belief that only by investigating phenomena under such simplified conditions can we really hope to understand them

Here, to the scientific mind, is in fact a definite and presumably soluble problem, that provided by 100 mgm or so of isolated muscle or nerve, capable of responding in a regular and reproducible manner to certain treatment academic—certainly so was the study of the conduction of electricity through gases—until it led to X rays and amplifying valves abnormal—if you like but still a fact, and one that presumably can be explained The irritability, the responsiveness, of this little bit of surviving tissue can be maintained, under conditions which we are beginning slowly to understand, for considerable periods and during all this time we can study the processes of life, in abnormal form if you wish, but still as phenomena, as facts, under conditions which allow us to apply the methods of physics and chemistry as we could never hope to do in the normal intact animal

Energy Exchanges in Nerve

The isolated nerve of a frog, placed in an appropriate salt solution containing oxygen, will live, or at any rate continue to function, for days We can detect its activity most readily by leaving it connected to a muscle, which will twitch when we stimulate the nerve A better method, since it involves the properties of the nerve alone, is to record the 'action current', which passes for a few thousandths of a second between electrodes placed upon its surface Another method, but more difficult to apply, is to measure the heat produced by the nerve when stimulated

For long periods the surviving nerve will show all the outward and visible signs of a response to stimulation During prolonged survival at rest it consumes oxygen and gives out carbon dioxide at 20° C about half a cubic millimetre per gram per minute, more at a high temperature, less at a low During maximal activity, due to continual stimulation, its metabolism is doubled, its oxygen consumption at 20° C is about one cubic millimetre per gram per minute It gives out corresponding heat Of this heat, only about one tenth appears during the passage of the impulse—the rest comes off slowly, during the following fifteen minutes clearly it is related to some recovery process, by which the nerve is recharged', by which its potential energy, so to speak, is restored

The fact that extra oxygen is used as the result of activity is, in a sense, easy to understand Breakdown has occurred, free energy has been liberated, and if the process is to be reversed, oxidation is necessary to supply the free energy required in the re synthesis The oxygen consumption at rest is much more difficult to comprehend Why should

[1] From the Ludwig Mond Lecture delivered at the University of Manchester on Mar 6.

an isolated tissue, doing nothing at all except continuing to exist—that is, continuing *to be ready* to respond to a stimulus—require what is in fact a considerable amount of oxygen, three quarters of its own volume per day at 20° C, three to four times its own volume at human body temperature? Energy, we may say, is required to maintain the organisation In what manner, however, is the energy being applied? What will happen if the supply of oxygen be stopped?

The last question is very readily answered by experiment The air around the nerve is replaced by pure nitrogen, and from the known diffusion constant of oxygen and the known oxygen consumption of the nerve, we can calculate that in a very few minutes not a trace of molecular oxygen is left A stimulus is applied at intervals, and the action current, or the heat, is used as a sign of activity At first no particular change occurs the nerve responds as before Long after *all* the molecular oxygen is gone, action current and heat production remain almost unaltered Even the recovery heat, which surely is of oxidative origin, is unaffected Presumably there is some source of intra molecular oxygen, or some store of hydrogen acceptor, which, for a time, can supply the energy required for recharge Gradually, however, a change comes on action current and heat diminish, and in two hours after the oxygen was removed they disappear together

The nerve, however, is not dead let oxygen in and it revives its return is gradual, much slower than the inward diffusion of the gas—the oxygen clearly has some duty to perform, some debt to pay, before the situation is cleared up The nerve asphyxiates much quicker a second time if its exposure to oxygen be cut short Indeed, by the admission of oxygen alone, complete recovery from asphyxia is not possible however long be the exposure to oxygen, subsequent asphyxia (as Gottschalk showed) is quicker than it was originally Washing the asphyxiated nerve with *oxygen free* salt solution restores it temporarily Complete restoration, however, is attained only if washing be combined with oxygen Then the nerve returns triumphantly to its full initial activity, apparently unaffected by the intervening period of asphyxia It seems as though, in the absence of oxygen, two things have happened (*a*) some metaphorical accumulators have run down and need recharging—a process which requires oxygen, and (*b*) certain abnormal substances have appeared, which cannot be removed by oxygen, but will diffuse away into surrounding salt solution

Potential Differences in Nerve

Many attempts have been made in recent years, before the latest and most successful ones, to measure the gaseous exchanges of isolated nerve Actually in the refined methods employed by Meyerhof and by Warburg, modifications of those of Barcroft, a means has long been available of making these important measurements When Downing and I succeeded at last in measuring the heat production of nerve, it seemed to us, and to Gerard who had joined us, that corresponding determinations of oxygen consumption should be carried out I wrote, therefore, to Meyerhof and asked him if Gerard could come to make these with him Meyerhof waited a day to reply his answer was, as I expected, "Of course, let Gerard come", but also, as I had not expected "es ist ausserordentlich leicht, I did it yesterday on the receipt of your letter" So Gerard went and made the experiments in Berlin At the same time Fenn was doing the same thing in his laboratory at Rochester, New York The oxygen consumed at rest, the oxygen needed for activity, and finally, the oxygen required for recovery from asphyxia, were all measured and are now tabulated for those who need to use them for their calculations

I mention these measurements partly for their own sake—as the happy ending to a long series of persistent attempts—but more particularly for a curious by product which, like many by products, is likely to prove more important than the original object An American worker, some years before, attempting to measure the carbon dioxide production of nerve, had employed a very convenient object, the limb nerve of the spider crab Reading his paper I noticed that, whereas he had stimulated the nerve for long periods, he gave no evidence that the nerve had really responded at all to his stimuli Knowing from experience of medical practical classes how often nerves do not respond to the best intentioned stimuli, I thought I had better try for myself So, being at Plymouth, where there are much bigger and better spider crabs than in America, I tried, and by good fortune a whole beautiful new field of work appeared

The experiment was a simple one A and B are two non polarisable electrodes placed upon the nerve, which for the sake of the argument we take as a single nerve fibre A is at an uninjured point, B at the cut and injured end A and B are connected to a galvanometer A difference of potential exists between A and B, the so-called injury potential, which produces what is called the 'demarca-

tion current' when it is allowed to flow through the galvanometer A is positive to B in the external circuit When we apply an induction shock to the nerve at a distant point C, the potential difference between A and B momentarily falls as the impulse passes A the current through the galvanometer diminishes we witness what is called the 'negative variation of the injury current' If we apply a succession of induction shocks at C, each produces its effect at A as its corresponding impulse goes by, and if the galvanometer be a relatively slow one, these effects are summed up, and as we continue stimulating, the galvanometer returns

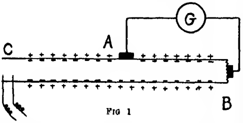

FIG 1

towards its zero, deflecting again when the series of stimuli ends Such, at any rate, is what happens in a frog's nerve The fact has been known for two generations it is demonstrated to students but curiously enough—so far as I am aware—nobody had ever tried to show it in a crab's nerve In that tissue, if stimulation be continued long enough—for a minute or two—the galvanometer does indeed move backwards during the stimulus towards its zero, recording the usual 'negative variation', but it does not return outwards again when stimulation ends

Let me pass for a moment to a fact recently established by Furusawa If a crab's nerve be kept in air in a moist chamber, the difference of potential between A and B is maintained for long periods If, however, the air be replaced by pure nitrogen, the difference of potential between A and B gradually diminishes On introducing air again it rises to its original value, not immediately but in an hour or so Clearly, oxygen is being used to maintain a potential difference somewhere within the nerve Where can this potential difference be other than at the surface of the fibre itself? At the cut end the electrode is in contact with the naked protoplasm of the cell at the uninjured point the electrode is in contact with the outside of the membrane surrounding the tissue We must imagine that the injury potential is really the difference of potential across the membrane of the nerve fibre, the contents of the fibre between B and A simply acting as a continuation of electrode B Apparently, then, Furusawa's observation shows that the potential difference existing across the membrane bounding the nerve is maintained by oxidation, and gradually 'runs down' if oxidation be prohibited

Picture the passage of the impulse along the nerve as being momentarily accompanied by a breakdown, or maybe a short circuit, of the membrane, perhaps by a change of permeability allowing local currents to run and so to propagate the impulse Thinking of the membrane as similar to an accumulator of small capacity, a series of such momentary short circuits might 'depolarise' it, so that by stimulation we might effect a decrease in the observed injury potential Now Levin found, and Furusawa has confirmed the fact, that a prolonged stimulus applied at C causes a return of the galvanometer towards its zero, which is not followed by a deflection outwards again when the stimulus ends Furusawa, moreover, has proved that if local fatigue at the point of stimulation be avoided by employing, in rapid succession, a series of such points, the nerve can be *completely depolarised by activity* The accumulator' which lies along the bounding membrane of the nerve fibre can, it seems, be caused to run down completely by prolonged activity Let us now withdraw the stimulus and wait If the nerve be in air, the potential difference between A and B gradually rises again until finally it attains its original value This is the recovery process to which I referred earlier If, however, the nerve be in nitrogen, it remains depolarised and further activity is impossible The potential difference existing across the boundary of the living cell is not only maintained but also restored by an active process of oxidation

Osmotic Differences in the Egg

In a recent paper from Holland by J Straub, an investigation has been described of the difference of salt concentration, and of freezing point, between the white and the yolk of an egg It appears that, in the living fresh egg, there is an appreciably higher concentration of potassium, sodium, chlorine, and lactate ions in the yolk, and an excess lowering of freezing point of about 0 15° C In preserved eggs this difference is much less The membrane surrounding the yolk is apparently freely permeable to water, even in its live condition, and the difference of freezing point on the two sides is much too large to be accounted for by any such effect as that of the Donnan equilibrium A difference of freezing-point of 0 15° would correspond to a difference of pressure of 1 8 atmospheres, and it is inconceivable

that a thin membrane so extensive as that surrounding the yolk could possibly stand a pressure such as this

It is difficult to resist the conclusion that the existence side by side of white and yolk cannot be regarded as a thermodynamic equilibrium, and Straub suggests that the difference of concentration on the two sides of the membrane is maintained by an active process of oxidation It is known that oxidation occurs in the living egg, and, according to a rough calculation, the amount of energy supplied thereby is ample to account for any osmotic work that would have to be performed to maintain, against diffusion, the observed concentration differences It is suggested that the observed inequalities in concentration and in freezing point must be due to some active life process, and the author discusses an electrical scheme for the employment of the energy obtained by oxidation in the egg He supposes that the membrane acts as a galvanic oxidation element for glucose, and that the difference of potential so set up across the membrane results in the transfer, against diffusion, of the various positive ions in question Such a galvanic battery existing across the membrane, together with differences in permeability, might be a sufficient explanation of the inequalities observed A large number of physiological phenomena would be more intelligible were we able to suppose that oxidation at the surface of a cell is largely employed in maintaining the osmotic and other differences that exist between the outside and the interior

Energy Exchanges in Muscle

In isolated muscle it has long been known that oxygen is necessary for the preservation of the excitable state A muscle left at rest in oxygenated salt solution maintains its condition for long periods if it be thin enough for the relatively slow process of diffusion to supply it adequately with that gas A resting muscle uses oxygen continuously at a rate depending on the temperature at 20° C this is about 0 7 cubic millimetre per gram per minute probably this process of oxidation at rest supplies the energy necessary in order to maintain the complex dynamic equilibrium of the living material in a steady state The known diffusion constant of oxygen through muscle, as found by Krogh, and the rate of its consumption, allow us to calculate that a thin sartorius muscle of a frog can easily remain in a steady state in oxygen just so long as combustible material is available The isolated muscle at 20° C uses about its own volume of oxygen per day and if it contains 1 per cent of glycogen this form of fuel alone should be sufficient, at that rate of oxidation, for some eight days Dissected aseptically and suspended at rest in a suitable salt solution a frog's sartorius will, in fact, if supplied with oxygen, function for a week or more

Deprived of oxygen, such a muscle produces lactic acid from its glycogen, the glycogen breaking down in this case about five times as fast as it did in oxygen If the lactic acid be able to diffuse away, as is the case when the muscle is suspended in oxygen free salt solution, the muscle lasts for a day or two, responding to a test stimulus at any time within that period finally, however, its excitability vanishes with the disappearance of its store of carbohydrate It may remain longer if glucose be included in the salt solution Apparently, if oxygen be not available, the breakdown of carbohydrate into lactic acid can replace the oxidation of carbohydrate as a source of energy Presumably, therefore, in the absence of oxygen, the formation of lactic acid is the process which supplies the free energy by which the dynamic equilibrium is maintained, by which, so to speak, the accumulators are kept charged

The term 'free energy', used in this connexion, should be understood in its strict thermodynamic sense It is interesting and important, as Burk has recently done, to calculate the free energy of the reaction by which, in living tissue, glycogen is broken down into sodium lactate We consider the whole process, dissolved glycogen transformed in the buffered alkaline medium of the muscle into dissolved sodium lactate Owing to the difference in chemical structure between the lactic acid and the glucose molecule, namely, in the ratio of the number of carbon atoms to the number of carbonyl oxygens, there is a considerable amount of free energy available in this breakdown, about 400 calories per gram of glycogen transformed For this reason, presumably, Nature has selected this particular reaction as the means of providing, in the absence of oxygen, the free energy required, either for doing work, or for maintaining (against diffusion and similar irreversible processes) the osmotic and other differences existing during life at the boundaries and other interfaces of the cell The free energy of the oxidation of glycogen is of course greater than that of its splitting to lactic acid it is about 4000 calories per gram If oxygen be absent a given process requires, let us say, 1 gram of glycogen to be broken down to lactic acid, yielding 400 calories of free energy the same process, if oxygen be present, requires only one fifth of a gram of glycogen to be oxidised, yielding 800 calories of free

energy 400 of the latter are wasted, apparently, in the recovery process

If, as I said, lactic acid is able to diffuse away, the muscle can continue to function until all its carbohydrate store is spent If, however, it be suspended in nitrogen and not in salt solution, its lactic acid cannot escape and the end comes on much earlier At 20° C in nitrogen a muscle produces about four millionths of its weight of lactic acid every minute about 0 3 per cent in 12 hours At this stage the increase in hydrogen ion concentration due to the accumulating acid renders the muscle completely inexcitable in less than 24 hours it attains the so called lactic acid maximum and passes into *rigor mortis*

The same processes can be observed to occur more rapidly when activity due to stimulation is substituted for resting survival A muscle subjected to a series of maximal induction shocks in nitrogen fails when it has given some 400 twitches, when its lactic acid concentration has reached about 0 25 per cent Suspended in oxygen free salt solution and stimulated with a frequency low enough to allow its lactic acid to escape by diffusion, it can give several times as many twitches (as my friend Kupalov has recently shown), and will continue until practically all its carbohydrate has been broken down, suspended in oxygen, or in oxygenated salt solution, it can give several thousand twitches and maintain its activity until all its carbohydrate is oxidised Moreover, as is now well known, if it be fatigued in nitrogen, and then allowed to recover in oxygen, its lactic acid vanishes and four fifths of the corresponding amount of glycogen reappears The free energy required for the reaction

$$\text{Lactate} \rightarrow \text{glycogen}$$

is provided by the oxidation of a fraction (about one fifth) of the lactic acid How this synthesis occurs, and what the chemical nature of its mechanism is, are not known but it undoubtedly does occur, and not only in muscle but also in practically every organ and tissue examined

The work of Warburg on the metabolism of tumour and other tissue is a highly important product of these studies originally conducted on muscle and earlier, in another form, by Pasteur on yeast It seems that nearly every kind of animal tissue employs the lactic acid breakdown, when deprived of oxygen, as the source of the free energy required for the maintenance—against irreversible processes—of its steady living state and that certain types of tissue, particularly those found in malignant growths, actually prefer the lactic acid mechanism and may be relatively incapable of employing that of oxidation

There is no reason to believe that when oxygen is present the processes at work are other than the sum, or the resultant, of these two The free energy of the lactic acid breakdown is apparently the source of the mechanical energy liberated by muscle, alike in the presence and in the absence of oxygen In the former case, however, a slow recovery process ensues, in which—perhaps under the action of a galvanic combustion element, as suggested by Straub for the case of the hen's egg—the lactic acid formed in the initial process is re formed into its precursor glycogen Moreover, the processes of resting survival and of activity are so similar that there appear to be strong grounds for supposing that, at rest also, the primary mechanism in which free energy is liberated (to counteract irreversible processes which lead finally to chaos and death) is that of lactic acid formation from carbohydrate

It is not a wild extrapolation from this, and from the work of Warburg, to conclude that the same is true in all animal tissues The living cell is a complex organised system of enzymes, interfaces, potential and osmotic differences, chemical substances infinitely improbable in the thermodynamic sense, and yet existing in a steady state so long as free energy is available to maintain the organisation The free energy of the carbohydrate-lactic acid breakdown is apparently the *sine qua non* of this maintenance, the common factor in the organisation of living animal cells The primary function of oxidation is the reversal of this breakdown

Reversible Inexcitability in Muscle

All who have worked with isolated muscles have found—alas, too often—that these may 'die' without apparent cause and spoil their experiments They do it more at some seasons than at others, often for weeks on end some muscles are worse in this respect than others and if we have not attributed it to the machinations of the devil (physiology leads many of us to a belief in that gentleman) we have been fain to call it fatigue', thereby expressing our ignorance of the whole matter If we knew that a muscle survived better in oxygenated salt solution than in oxygen gas, we talked about the removal of 'fatigue products' in the former, even though the muscle—being supplied with oxygen and at rest—was never fatigued at all It took two chemists, Dulière and Horton, to detect what physiologists should have recognised long ago, that a state of reversible inexcitability sets in spontaneously in isolated dissected muscles It is true that some years ago, in the biochemical laboratory at Cambridge, it was shown that the legs of frogs, kept

at a low temperature in oxygen, gradually in the course of a week or so lose their irritability, which can be restored by soaking in salt solution. It is not certain, however, that this is the same phenomenon, and in any case Dulière and Horton have demonstrated it in much more striking and—one might almost say—provoking form.

A sartorius muscle is dissected with the utmost care from a frog and suspended in moist oxygen, or nitrogen, or air; silver or platinum electrodes are brought in contact with it and at intervals its response is tested. At first stimulation leads to an active contraction; as time goes on, however, the muscle apparently dies; it is not fatigued, it has been quite infrequently stimulated, and in oxygen or air there should not be, and in fact there is not, any accumulation of lactic acid. In an hour or two the muscle is apparently dead, it responds not at all to the strongest stimulus, though if it be taken out and tested chemically it is found to show all the chemical characteristics of resting muscle.

The phenomenon is not due to oxygen as such, or to the absence of oxygen; it cannot be attributed to surrounding the isolated muscle by a gas, since it happens also in liquid paraffin and mercury. I called it 'reversible'. Immerse the muscle, when it has become completely non-excitable, in salt solution, and its excitability returns, rapidly at first, more gradually later, following approximately a course we should expect were the return of excitability due to the outward diffusion of something present in the muscle. Any reasonable salt solution will cause a return of the excitability: Ringer's solution, sodium chloride,—anything, in fact, which does not itself lead directly to inexcitability in the muscle.

It would be easy, so far, to imagine that some product of activity in muscle, gradually accumulating, produces a toxic effect which leads to the inexcitable state. This simple suggestion, however, is not sufficient. If we soak a muscle, for three hours after removal from the animal, in salt solution, and then suspend it in a gas, it will remain excitable indefinitely. If we wash it for three hours after it has become inexcitable, its returned excitability will remain indefinitely, that is, until its carbohydrate reserves are used up or bacterial invasion sets in. If, however, we wash it for a shorter time, say for half an hour, after it has become inexcitable, its excitability indeed returns, but when we place it again in a gas, it becomes inexcitable once more. Not until the sum of the times of immersion has attained a certain value does the muscle become permanently excitable in the present sense. If any product of metabolism has a toxic effect, why should further metabolism after a 3 hour preliminary soaking in Ringer's solution now have no result? Are we dealing here with the same curious phenomenon as Furusawa found in the case of a crab's nerve? Moreover, why do the muscles of a frog's leg, allowed to remain *in situ* after the death of the animal and the removal of the skin, retain their excitability for hours, while a companion muscle dissected out and, to all intents and purposes, uninjured, becomes inexcitable in an hour? The muscle is not dead, for it shows a normal resting metabolism and can be revived by washing with salt solution; it may then live for days, which is a sign that any injury due to dissection is of negligible importance. Is the effect of a subtle physical nature, due to contact of the living tissue with a medium of unusual dielectric constant? Or is it to be attributed to the production of some substance, in or between the cells, which can be washed away by contact of the muscle with salt water? The phenomenon is an easy and dramatic one to witness, once one realises its existence, but a difficult one to explain. The realisation, however, that it occurs has greatly simplified experiments with isolated muscles, for we know now that by a preliminary period of washing we can prevent an occurrence which has spoilt so many experiments.

There is one possible explanation. If a Ringer's solution be prepared containing four times the usual concentration of potassium chloride, a muscle immersed in it slowly becomes inexcitable. One which has become spontaneously inexcitable by standing in oxygen shows no return of excitability when immersed in this solution. We might have expected a temporary return. A muscle consists of fibres and interspaces, mainly fibres. In the inside of the fibres there is a very high concentration of potassium, in the interspaces a low one. Excitability may depend—among other things—upon a normal concentration ratio of potassium across the boundary of the cell. Experiments have shown that when muscles are perfused, potassium tends to leak into the perfusing fluid. If it leaked into the interspaces between the fibres—not much would be required—it might gradually produce the same state of inexcitability as we can cause by the artificial application of a high potassium concentration. The chief difficulty in this explanation, which has much else to commend it, is that one cannot see why a few hours' immersion in salt solution should prevent any further egress of potassium. In any case it seems that the phenomenon is of a physical or of a physico-chemical nature, and has no connexion with the oxidative mechanism of the cell.

Anaerobic Disintegration in Muscle

I come lastly to the most difficult problem of all: the cause of a phenomenon which I discovered in 1927 and about which I speculated last spring, perhaps rather rashly, in the *Proceedings of the Royal Society*. I say rashly, partly because my paper was the innocent cause of much excitement in the autumn, when the public Press discussed—in the 'silly season'—the 'mystery of life'; partly because the explanation I originally gave may not be sufficient. The facts, however, seem certain, and are these: By improvements in technique, the rate of resting heat production of a muscle can be measured, in oxygen or in nitrogen. The muscle lies in nitrogen upon the warm junctions of a thermopile, in a thermostat maintained at a constant temperature. The rate of the resting heat production at 18° C. is (say) 60 gm. cm. per gram per minute: about 1½ thousandths of a calorie. The muscle has previously been washed for some time in salt solution, so that it does not now become spontaneously inexcitable in the manner described by Dulière and Horton. It is stimulated and gives a series of twitches: the heat due to activity is registered by the galvanometer attached to the thermopile: stimulation ends: the galvanometer returns: we should expect it to return, gradually, of course, to its original position, the muscle to revert to its original heat rate. Nothing of the kind. I may illustrate what happens by a typical experiment.

Time A.M. or P.M.	11 56	11 59	12 1	12 2	12 3½	12 5	12 6
Galvanometer deflection mm.	22	23½	23½	22½	22½	24	23

The muscle was then stimulated by single shocks to fatigue: the galvanometer deflected, and, when the stimulation ended, returned to rest once more.

Time P.M.	12 20	12 23	12 25
Galvanometer deflection mm.	130	130	130

The resting heat-rate in this case has been increased between five and six times.

The phenomenon has never failed to appear, and it occurs always in the same quantitative form. The quotient

$$\frac{\text{increment in heat rate per minute}}{\text{total heat by stimulation}}$$

is always (in the frog's sartorius at 17° C.) of the order of 0·0075. The high heat rate induced by stimulation is permanent so long as the muscle remains in nitrogen. It may attain 800 gm. cm. per gram per minute after severe fatigue—more than 1 calorie per gram per hour. It may remain at this level, so long as the muscle is kept in nitrogen, for 24 or even 48 hours, in which time the total heat liberated may be many times as great as can possibly be accounted for by the breakdown of *all* the available carbohydrate into lactic acid. Since, apart from carbohydrate, there is very little except the actual protein of the muscle which we can imagine to break down with such an evolution of heat, we are forced to conclude that the process of anaerobic activity (or its products) has somehow induced the degradation of the muscle protoplasm itself to bodies containing less total energy.

If, when the muscle has been fatigued in nitrogen, and its resting heat rate is high, we admit oxygen, a recovery process sets in as usual, with a considerable evolution of heat. The lactic acid is removed and the muscle is restored to its previous resting condition. This occupies about an hour. If, now, we replace the oxygen by a stream of pure nitrogen, within half an hour diffusion on one hand, and the resting metabolism of the muscle on the other, have removed the last traces of oxygen from the interior of the muscle substance, and the resting heat rate in nitrogen can again be measured. Instead of the high value found after stimulation, we now observe a low value of the same order of size as before it. The breakdown processes produced by anaerobic activity have been cut short and the muscle has regained its previous steady state. The same treatment can then be applied once more. If the muscle be stimulated to fatigue again its resting heat rate rises: if oxygen be again admitted recovery ensues, and finally a low value of the resting heat rate appears as before.

There seem to be two alternatives: either (1) the provision of energy by oxidation has restored to their normal state the membranes, interfaces, or agents, which in ordinary life hold apart the unstable reacting substances present in the living cell, which prevent—as I said in my paper—the organised system of the living cell from becoming a biochemical chaos; or (2) in the presence of oxygen some substances have been removed, perhaps by simple oxidation, perhaps by restoration to a precursor, which, if they be allowed to remain, assist as catalysts, or in some other capacity, in the anaerobic disintegration of the living material. One thing seems certain—the high heat rate *is* a sign of some kind of irreversible breakdown or disintegration: if—as Kupalov has shown—it be allowed to continue for a few hours, no subsequent restoration of the muscle to its normal excitability is possible, either in oxygen or in oxygenated salt solution.

The phenomena in question are so curious, and the effects so relatively large and so easily demon-

strated, that they demand an explanation They have been tested by every means available and have withstood the attack Were they due to a change in the hydrogen ion concentration caused by the liberation of lactic acid ? A resting muscle was immersed in pure carbon dioxide and its heat rate remained practically unaltered the carbon dioxide must have made it as acid as extreme fatigue Were they due to a technical error of some kind ? To a reaction of some fatigue product with the metals of the thermopile ? The thermopile was insulated with baked 'Elo' (an artificial resin), shellac, and paraffin wax on top of these a piece of tin foil and over this a further layer of wax The phenomenon appeared quantitatively as before It is inconceivable that breakdown products of muscular activity can penetrate wax, tin foil, wax, shellac, and 'Elo', one on top of the other Was it due to injury in dissection ? It was found unaltered in a frog's gastrocnemius, which can be prepared with a minimum of injury The temperature was lowered to 0° C The high heat rate existing in a fatigued muscle diminished to one sixth, which is what we should expect were it due to a chemical process occurring continuously, not at all what we should look for were a technical physical error the basis of the phenomenon

I was inclined, when I first described the phenomenon, to the first of the two alternatives just mentioned, to the belief that oxygen restores the normal interfaces, or conditions, which prevent the organised system from becoming a biochemical chaos During the last few months, however, I have come across another effect which inclines me a little to the second alternative—perhaps both are correct The experiment is a simple one and the result quite certain it ought to have been made long ago but one only thinks of these things slowly If a muscle showing a very high resting heat rate induced by anaerobic stimulation be immersed for an hour or two in *oxygen free* salt solution, its heat rate returns to its original low level the muscle need not even be alive it may have been 'electrocuted' by excessive stimulation, it may have been irreversibly damaged by too long a maintenance of its high heat rate in nitrogen Yet, under the influence of the washing, in a time which suggests diffusion outwards of some catalysing agent, the breakdown evidenced by the previous high heat rate is completely—or almost completely—stopped Clearly, oxygen as such is not necessary for a reversal of the effect Perhaps if lactic acid be not already present in excessive amount, the lactic acid breakdown can take the place of oxidation in the maintenance of the normal internal architecture of the cell perhaps, however, *something* is set free in the absence of oxygen, which induces—or helps to induce—the irreversible breakdown of the muscle protoplasm with a liberation of energy a something which can be dialysed away by immersion of the muscle in salt water

It is well known that, in man, too prolonged exposure to anoxæmia may produce harmful effects lasting for a long time or even permanently As Haldane writes "A short exposure even with loss of consciousness produces no serious after symptoms but occasionally a man's behaviour is very abnormal for a few minutes after recovery" "With severe and prolonged exposure to want of oxygen the nervous after symptoms are of an extremely formidable nature and often end in death" "The symptoms are evidently due in the main to widespread injury to the nerve cells during the exposure" "The heart may also suffer in prolonged exposure to want of oxygen The after symptoms may be mainly cardiac, it may be a considerable time before the heart fully recovers" "Probably every other organ and tissue in the body feels the after effects of severe exposure to want of oxygen The patient often enough dies of pneumonia Acute nephritis and gangrene of extremities have been noted" And so on May we not be witnessing here in man the after effects of the same partial disintegration of the living protoplasm as can so easily be demonstrated in anoxæmia in the isolated muscle ?

In Warburg's work we find further evidence of a harmful effect of oxygen lack An embryo of a chick is kept for some hours in salt solution saturated with nitrogen oxygen is then introduced In the normal embryo there is practically no lactic acid formation if sufficient oxygen be present the free energy required for continued existence is supplied by oxidation In the embryo which has been subjected to a period of anoxæmia, however, the capacity for oxidation is found to be diminished and a large part of the energy it requires must now be derived from the lactic acid breakdown By anoxæmia, in fact, the normal embryo has been reduced to a state in which its metabolism is similar to that which Warburg has found to characterise tumour tissue Can it be, as Warburg's work suggests, that oxygen lack, working upon the normal architecture and machinery of the cell, leaves behind a type of mechanism analogous to that of tumour ? Dare we see in the disintegrative process set up by anaerobic activity in the isolated muscle cell an exaggerated case of the harmful effect produced in man by prolonged and severe anoxæmia, or in the chicken embryo by oxygen want ? It is dangerous to speculate too far, but it is foolish not to speculate at all

Printed in Great Britain by R. & R. Clark, Limited, Edinburgh.

learn to look at architecture as it might appear to an observer from another planet, to whom its human origin was unknown, and on the whole this detachment is more nearly attained by the landscape painter than by the historian or even, perhaps, the architect himself

The old towns of the Riviera crowning the foot hills of the Alpes Maritimes, or capping promontories which project against the blue Mediterranean, provide as usual the subject for one kind of culmination of natural in architectural form Of the purely natural landscape of this delightful coast there are as usual several studies, of which Mr H Van der Weyden's The Lone Pine of La Mortola (208) is the most considerable, but it is to be regretted that the landscape of the tropics should be almost unrepresented in the Exhibition The gamut of the emotions evoked by the world's scenery remains incomplete so long as the tropics are passed over, and the traveller longs to see at least something which will recall the coast with fringe of waving palms and the gleam of green translucent water within the coral reef, with its line of foaming breakers and deep blue sea beyond

Among the artists who are enterprising in their research for natural effects Mr W L Wyllie is certainly to be reckoned, and in Fifty North and Forty West (207) he gives us the impression of an occurrence which is never seen without a thrill of excitement, the sudden breaking away of the whole summit of a great dome shaped wave in the foaming cap which sailors call a 'cauliflower sea', which, launched bodily forward, is here seen rolling towards the observer

Such were the aspects of Nature, or the emotions aroused by aspects of Nature, which I found observed and recorded by our fellow students, the landscape painters in this year's Exhibition of the Royal Academy

News and Views

IN his Ludwig Mond lecture, delivered recently at the University of Manchester, the main part of which appears as a supplement to this issue of NATURE, Prof A V Hill refers to the value of experiments carried out on isolated animal tissues for the elucidation of the phenomena of life, and illustrates his thesis with descriptions of some recent work performed on the isolated nerve and muscle of cold blooded animals Both tissues consume oxygen not only as a result of activity but also whilst at rest it appears that not only is the production of energy in the form of a nerve impulse or a muscular contraction accompanied, or followed by, the consumption of oxygen, but also oxygen is required for the process of remaining alive and irritable, of being ready to respond to a stimulus The isolated muscle uses the absorbed oxygen to oxidise glycogen, in the absence of oxygen, lactic acid is formed from the glycogen, which breaks down much more rapidly than in the presence of oxygen, and the free energy of this breakdown suffices to maintain irritability in the muscle for a short time, provided that the lactic acid is removed by immersing the muscle in saline In the presence of oxygen a portion of the acid is completely oxidised, but the remainder is resynthesised to glycogen, so that in the presence of oxygen the muscle lives much longer than in its absence

THE next step in the chain of evidence given by Prof Hill is the result of studies of a muscle stimulated in nitrogen to fatigue The heat production at rest after the stimulation is much greater than before, and may in time exceed the amount that can be obtained by the breakdown of all the carbohydrate into lactic acid, indicating that the muscle protein is also breaking down The resting heat production can be reduced to its low pre stimulation level by immersing the muscle in oxygen free saline or by supplying it with oxygen The exposure to nitrogen, then, appears to have initiated a degradation of the muscle protoplasm which can be stopped by again admitting oxygen, or by washing away some substance which may be supposed to aid the protoplasmic breakdown In any event, the deleterious effects of asphyxiation appear to be due to disintegration of the cells of the tissue themselves, and, conversely, oxygen is necessary for the maintenance of cell structure Put in other words, Prof Hill argues that the living cell may be considered to be in a state of dynamic, as opposed to static, equilibrium, and therefore to require a supply of oxygen for the maintenance of its very structure

ON Monday next, May 13, Messrs Sotheby and Co will offer for sale a collection of letters (1743–1820) from and to Sir Joseph Banks, president of the Royal Society They are being sold by a collateral descendant of Dorothea Lady Banks, wife of Sir Joseph Banks The series includes botanical and horticultural letters and papers of Australian interest—communications to Banks from the early governors of New South Wales—also letters of Matthew Flinders, George Bass, and Bligh It would seem improbable that any have been published, no indication, however, is supplied as to this The correspondence is suitably secured in handsomely bound folio albums, each having a list of contents, though unfortunately no numbers are given to accord with the sequence of letters, thus reference is tedious

AMONG miscellaneous matter (Lot 7) we notice a letter of Thomas Young, in a fine script, addressed to Count Rumford at the Royal Institution and dated July 9, 1801 It refers to his appointment to the professorship of natural philosophy 'As to the journals", he says, "I should not much object to engage that a sheet or more should be read for publication every week, but I conceive that it would give them additional importance if it were left to the discretion of the professor, with the approbation of the committee, and with proper notice, to publish a number at the end of a fortnight instead of a week, whenever there might appear to be a real deficiency of

matter to fill it As I think I should want little or no assistance either in translating or transcribing, except what Mr Davy might have the goodness to give me, I hope when you have reconsidered what I have stated you will not much differ from me in opinion "

AT Oxford, on May 4, under the auspices of the Society of Friends of the Old Ashmolean, a public lecture was delivered by Prof D'Arcy Thompson on "The Hellenic Element in the Development of Science" It was shown that Aristotle's doctrine of excess and defect, applied by him in the region of biology as in that of ethics, was in accordance with conceptions of Greek mathematicians in regard to the theory of numbers, especially as developed in later times by Theon of Smyrna in the series known as the 'indeterminate' or 'boundless' dyad The geometrical aspect of number was always kept in view by the Greeks, Euclid's treatment of the square of the hypotenuse exemplified this, and his whole system culminated in the dodecahedron with its pentagonal surfaces Much of the fabric of modern science has its foundation in the mathematical conceptions amplified and illuminated by the genius of the Greeks, but shared with them by other peoples, as by those of Egypt and Chaldea The lecture, which was largely attended, was followed by a meeting at which various donations to the Lewis Evans collection were announced, and means were considered for increasing the membership of the above mentioned Society

ON Saturday, May 11, Lord Birkenhead is to unveil stained glass armorial windows given for the embellishment of the staircase of the Old Ashmolean Building, Oxford Two armorial windows are being added to those already in the Museum to commemorate the foundation gift of historic scientific instruments by Dr Lewis Evans, and in gratitude to four of the great City Companies which by timely benefactions made it possible for the University to install the Evans collection in the Old Ashmolean, and thus to fulfil the condition on which it was offered to Oxford The Evans window is presented by certain members of the Society of Friends of the Old Ashmolean, chief among whom was the late Lady Osler It is inscribed LUDOVICUS EVANS, D SC, QUI MUSEUM ASHMOLEANUM DENUO LOCUPLETAVIT INSTRUMENTIS NATURALIS SCIENTIAE COLLATIS HIC COMMEMORATUR MCMXXV The second window, given by Sir Dugald Clerk, bears the arms of the Companies of the Goldsmiths, Ironmongers, Clothworkers, and Fishmongers It is a delightful composition, and a reminder of their many services on behalf of education The inscription runs MUSEI ARMARIA INSTRUXIT ET ARCAM DITAVIT GILDARUM LONDINIENSIUM LIBERALITAS QUARUM INSIGNIA DEPINGENDA CURAVIT DUGALDUS CLERK MCMXXIX The earlier windows commemorate Elias Ashmole, the first founder of the Museum in the seventeenth century, and his friends, John Tradescant the younger, Dr Plot, and Sir Christopher Wren The new windows which Lord Birkenhead is to unveil relate to the re founding of the old Museum in the twentieth century after a lapse of thirty five years, during which it had been allowed to fall into a neglected state

AMONG the portraits in the exhibition now open at the Royal Academy, that of Sir Ray Lankester by Sir William Orpen is acknowledged to be the outstanding picture of the year The fundamental note of the picture is that of declining years, yet the harmonies give it wonderful tone There is still an inquiring look in the face, with its fine forehead and the clear, steady eyes which always seem to mirror thought and observation, while the beautifully formed hands are given their full value in an easy attitude which seems to signify rest after labour Another very successful portrait is that of Prof J Millar Thomson, emeritus professor of chemistry, King's College, London, by Mr P A Hay Mr Richard Jack exhibits a fine picture of Lord Moynihan, president of the Royal College of Surgeons, and other portraits of people well known in scientific circles are those of Mr E F C Trench, past president of the Institution of Civil Engineers, by Mr George Harcourt, Mr W Tapper, president of the Royal Institute of British Architects, by Sir William Orpen, Mr J L S Hatton, principal of the East London College, by Mr Augustus E John, Prof Priestley Smith, emeritus professor of ophthalmology, University of Birmingham by Mr Harold Speed, Sir Hugo Hirst, chairman and managing director of the General Electric Co, Ltd, by Mr Richard Jack, and Mr A S Ramsey, president of Magdalene College, Cambridge, by Mr Francis Dodd There is also a bust in bronze of Col R E Crompton, by Mr George H Paulin, and a miniature of Prof J P Hill, by Elizabeth A Steele

THE fourth Huxley Memorial Lecture of the Royal College of Science was delivered by Prof F O Bower, at the Imperial College of Science and Technology, on Friday, May 3 the title being "The Origin of a Land Flora, 1908–1929" Prof Bower began by referring to his book "The Origin of a Land Flora", published in 1908 He summarised the theory of 'interpolation' there put forward to account for the origin and progression of the spore bearing plants, the dominance of which is so striking in all land plants from the ferns upwards He then indicated the more important modifications in the view expressed twenty one years ago which have resulted from advances in botanical knowledge The chief of these concern, first, the expansion of our knowledge of alternation of generations in the brown and green algæ and the significance of the cytological distinctions between the two generations in these plants Secondly, the outlook has been changed by the increase in the knowledge of the very simply organised plants now known to have existed in early Devonian times, thirdly, a study of the embryology of the Psilotaceæ has shown that this group now stands nearest to these ancient fossils

GIVING these new facts and others their full value, Prof Bower holds that his position as stated in 1908 needs "neither reversal nor obliteration but only modification" He suggested that the remote ancestors of the Archegoniatæ were of the same general type as the Green Algæ, but in these ancestors the act of meiosis was deferred, and a diploid phase

interpolated which was structurally suited to sub aerial conditions and bore numerous spores These plants would thus at one stroke achieve three bio logical advantages of prime importance (1) a multi plication of possible combinations of hereditary characters (as suggested by Svedelius), (2) an opportunity of securing a wide spread on dry land by the dissemination of spores, and (3) relief from dependence on repeated syngamy by numerical increase on land, where the necessary medium of external liquid water is not always available In conclusion, Prof Bower pointed out that while the gap between the Algæ and the Archegoniatæ is still open, and indeed remains as in 1908, yet the evolution of the constituent parts of the land living sporophyte can now be traced with the aid of the early Devonian plants

According to a recent *Daily Science News Bulletin* issued by Science Service, Washington, D C, a notable invention was announced to the National Academy of Sciences on April 19 by General G O Squier, the inventor of 'wired wireless' The principle of wired wireless is the same as that used in sending telegraph or telephone messages over lines carrying signals of different frequency or over power lines The new method, which is called the 'monophone', is the per fection of a form of radio transmitted partly by telephone wires In America the ether is incon veniently crowded with messages of all kinds It is now proposed to make the ordinary telephone wires carry some of these so as to relieve the congestion In particular, without interfering with the present point to point service of the broadcasting and without change of equipment, the telephone wires can be made to work sixteen hours a day, bringing the broad casting programmes to the householder It is sug gested that this 'line radio' could be made to provide a method of financial support to the broadcasting companies, thus eliminating the necessity of broad casting advertisements both directly and indirectly The small power used in this system is also claimed as a further advantage The power taken by a small incandescent lamp would be sufficient to supply five thousand telephones When operating the telephone connected set, no tuning would be necessary To get a new programme all that is necessary is to turn a switch Fading and the various kinds of interference which prevent good broadcast reception would be eliminated There would be no difficulty in receiving sound motion pictures and television by this method It could be usefully employed for educational purposes

Another development in broadcasting was de scribed by Prof A L Foley, of Indiana University, in a paper read on April 23 to the National Academy of Sciences, on a new type of microphone for use by broadcasters and public speakers It is still in the experimental stage, but as the principle is novel it is considered to be very promising It contains no moving diaphragm A usual type of microphone (or 'mike' as it is frequently called in America) is the condenser microphone A thin diaphragm of metal is hung in front of a metal plate with an air space between them Both have electrical charges, and as the diaphragm is pushed or pulled by the sound waves the electrical charges fluctuate in value and electrical currents flow Some of the energy is radiated into space and picked up by the receiver's set The difficulty with any type of diaphragm is that it has free vibration periods of its own which it tends to assume, thus distorting the forced vibrations due to the sound waves In Prof Foley's micro phone there are only two solid metal plates with an air space between them The sound waves of the speaker's voice directed between the plates cause alternate condensations and rarefactions of the air As the air is acting as the dielectric of the condenser formed by the plates, the rapid changes in its density cause alternating currents in the plates, which are used to radiate energy into the ether Prof Foley says that the new device is in process of development and will not be on the market for some time

There is always interesting matter in the Annual Report of the Zoological Society of London, the centenary celebrations of which were referred to in our issue of May 4 The outstanding feature of this year's report is the remarkable record diagrammati-cally presented in its "Century Chart of Progress" On the whole, the chart shows a steady record of pro-gress, apart from a slack period which began in 1839 and continued for about thirty years But the extra-ordinary rise in the numbers of members and of visitors to the Zoological Gardens in Regent's Park, and in income, which commenced in 1910 and has carried the Society from height to height in almost unbroken leaps, is witness to the success of the policy of Dr Chalmers Mitchell and the Council, and perhaps also to an increasing love of entertainment which has seized the people of Great Britain There has been a certain increase in the numbers of deaths, especially amongst mammals and birds, but this is attributed to the increased size of the collection, and the installa-tion of electric heating and lighting into more of the houses in the Gardens shows that every effort is being made to ameliorate the living conditions No indication is given of the effect upon general health and mortality of the electric systems already installed Such information, based upon the definite records of the pathologist, would afford an invaluable guide to other zoological gardens at home and abroad which, on account of the great cost, hesitate to install electric fittings until their value has been clearly proved

The second number of the *Realist* continues some of the subjects begun in the first and gives a clearer idea of the general idea which the promoters have in mind It is to be a journal of scientific humanism, and this must mean treating of matters of living human interest in the light of scientific research It does not at present offer any review of scientific works or attempt to summarise the recent additions to our knowledge, but matters of current moment and discussion are taken up and suggestions made as to the lines of future development The emphasis, in fact, is rather strongly laid in these opening numbers on the present and still more, the future The first article in the May issue, by G E G Catlin, deals in this spirit with the 'Next Step for Democracy'

The outstanding point in the recent American presidential election is well taken Both candidates were in the true sense realists and represented a great advance in the political sense of the democracy which adopted them as its champions It is clear that in the modern conditions of extreme complexity and world wide extent of industrial and social relations, real expertness is needed in those actually in power It is also apparent that control of the industrial conditions and relations of one State and another has already become more important than the merely political relations of the old governments and diplomacy This involves more scientific expertness on the part of the governors and a better appreciation of such expertness on the part of the governed

MOST of the other articles in the *Realist* for May strike a similar keynote to that sounded by Prof Catlin That on the "Crisis in Psychical Research", by Mr E J Dingwall, will interest a good many people by its suggestion for a new thoroughly sound and independent investigation of recent phenomena of a spiritualistic kind The point is made that the Society for Psychical Research, which was founded to do this very thing, has lost its standing as a scientific body just at the time when the phenomena to be investigated have become more numerous Dr Charles S Myers gives an account of the work and the results of the Institute of Industrial Psychology Cases are quoted in which not only greater industrial efficiency has been secured and sickness among employés has been reduced, but also the earnings of the workers have been increased Mr H Martin Leake has a somewhat similar plea for the rationalisation of British agriculture Dr Norman Haire concludes his account of the recent experiments in rejuvenation, mainly of Voronoff and Steinach He sounds a fairly hopeful note while admitting that it is at present impossible to decide whether any of these procedures actually prolong life in a human being Dr A P Laurie has a short but very interesting and convincing defence of the scientific analysis of the materials and methods of the old masters Much of this has appeared in letters to the *Times* and it is useful to have it collected The editor, Major A G Church, has an equally persuasive article on the need of applying scientific methods to the development of our imperial possessions This is imposed upon us, both by our monopoly of so much of the world's richest soil and the 'sacred trust' which we have professed to the world for the well being and development of the backward races

THE curators of the University of Edinburgh unanimously agreed to offer the principalship—which will become vacant on Sept 30 by the resignation of Sir Alfred Ewing—to Sir Thomas Holland, Rector of the Imperial College of Science, London, who has accepted the appointment Sir Thomas is at present in South America, and the negotiations have been completed by cable He is to be president of the British Association during the forthcoming meeting in South Africa, and it is understood he will not arrive in Edinburgh until about the middle of October He will take to his new office a wide experience—academic and administrative—and extensive first hand knowledge of conditions in the Dominions and in India, a matter of great importance to the University of Edinburgh, which has more students from over seas than any other university in Great Britain

AT the meeting on May 2 of the Linnean Society of London the following honorary members were elected Dr Theodor Mortensen, superintendent, Zoological Museum, University of Copenhagen, distinguished for his researches on Echinodermata and other marine organisms, Prof Carl Hansen Ostenfeld, professor of botany and director of gardens and museum, Copenhagen, distinguished for his researches on the taxonomy and distribution of arctic plants, and also on cytology, heredity, and phytoplankton, Prof Bohumil Němec, professor of plant anatomy and physiology, Charles University, Prague, distinguished for his researches in cytology, physiology and anatomy of higher plants, and in mycology and bacteriology The presidential address of the Society will be delivered at the anniversary meeting on May 24, when the Gold Medal will be presented to Prof Hugo de Vries, who, unfortunately, on account of ill health, will not be able to be present

THE fortieth anniversary of the completion of the Eiffel Tower in Paris was celebrated on May 2 by the unveiling of a bust of Gustave Eiffel at the base of the tower The ceremony was performed by M G Martin, Secretary for Posts and Telegraphs, who paid a tribute to the great engineer Eiffel was born at Dijon on Dec 15, 1832, and died in Paris on Dec 28, 1923 He was a student of the École Centrale des Arts et Métiers, he obtained a wide experience of engineering construction, and by 1887, when he began the Tower, had built iron and steel bridges, etc, of more than 100,000 tons total weight The Tower, which is 984 feet high, is still the highest structure in the world It is a resort of sightseers, but it is also used as a wireless and meteorological station Nearly 14,000,000 persons have ascended the Tower since its construction Eiffel served as president of the French Society of Civil Engineers and was also an honorary life member of the British Institution of Mechanical Engineers

THE Ministry of Health has issued a statement respecting the present situation in regard to smallpox Smallpox of a mild type has been prevalent in England and Wales during the last few years, and in 1928 there were 12,420 cases with 53 deaths The distribution of the disease has been relatively wide, but it has been kept under control or stamped out in all of the 35 or 40 counties in which it has appeared, except in some five to ten districts where it has obtained a greater hold, owing in particular to neglect of vaccination In the Administrative County of London, with a population of 4½ millions, only 167 cases have occurred this year Some uneasiness has been occasioned by cases derived from the s s *Tuscania* This vessel arrived from Bombay at Marseilles on Mar 27 with passengers and crew numbering 1589, afterwards proceeding to Liverpool and Glasgow In all, 45 persons from the *Tuscania* have been notified as suffering from smallpox, of whom 7 have died,

but there is reason to think that this epidemic is now at an end, and as a result of the rigorous measures taken, English ports have been kept free

THE Yorkshire Naturalists' Union, founded in the sixties of last century, is one of the oldest, as it is one of the most flourishing of the amalgamations of natural history societies in Great Britain The Annual Report for 1928 states that the affiliation includes thirty eight local societies, and the summaries of work accomplished by the various sections of the Union show how active is the interest taken in the fauna, flora, and geology of the county The official organ of the Union is *The Naturalist*, a magazine the usefulness of which as a medium for the publication of natural history in all its branches is emphasised by the absence of an all England magazine of the same kind It is a remarkable fact that, since *The Zoologist* died, a Nature loving country like England should possess no periodical dealing with general natural history on the lines followed by that much lamented journal

THE Government Museum at Madras, under the superintendence of Dr F H Gravely, and, during his absence in Europe in 1927, of Prof E Barnes, continues to make good progress Like other progressive museums, it finds that detailed specialist collections are unsuitable for exhibition, and accordingly the Bruce Foote collection of prehistoric implements has been stored for reference, and the valuable exhibition space which it occupied has been given over to a much needed expansion of the ethnological collection The Buddhist sculptures have been rearranged, and a description of part of this exhibit is in the press, and various improvements have been made in the zoological and the coin collections Appendices to the Administration Report for 1927–28 show that the Museum receives a very small proportion of its material as gifts from the public, and that a surprising number of coins and of copper statues of saints and kings turned up as treasure trove in the villages of the Presidency

A SOMEWHAT alarmist article on "Fundamentalism in England", by Maynard Shipley, appears in the March number of *Evolution* Among other statements, it alleges that "much anti scientific propaganda is being 'put over' in the smaller provincial towns and vast districts of Wales, Ireland, and Scotland, where people still believe in witchcraft, as firmly as our 'Pennsylvania Dutch' towns where no hint of modern scientific thought has so far penetrated" So far as our experience goes, Mr Shipley's statement, as it refers to Scotland, at any rate, is as shaky as his composition We have never denied that there is a strong undercurrent of dislike to the theory of human evolution in the British Isles, but it is the 'die hard' resistance of conservatives who do no more than wish their old fashioned beliefs to be left alone. It certainly does not express itself in active and fussy propaganda, and much of it will die with its generation As for witchcraft in Scotland, the most we can say is that a canny Scot may occasionally believe in luck, but even evolutionists of the highest standing have been known to risk their chances at the casinos of Europe

SOME four or five years ago Dr Percy R Lowe, of the British Museum (Natural History), discussed with the eminent French ornithologist, M Jean Delacour, plans for a joint Franco British Expedition to Madagascar to collect specimens of both living and extinct animals which might possibly supply further clues to the origin of the fauna of this, one of the most interesting islands in the world What was most desired was the discovery of more remains of the extinct ostrich like fossil known as *Mullerornis*, which may throw light on the past history of all struthions, or ostrich like birds, and incidentally perhaps of the island itself Another most welcome discovery would be a complete skeleton of the giant flightless bird *Æpyornis maximus*, which stood at least ten feet high Funds for such an expedition have now been provided by Mr Arthur Vernay, and the Trustees of the British Museum have loaned the services of a palæontologist, Dr Errol I White, who is due to arrive at Madagascar towards the end of May At the last moment the Expedition has been joined by a party of American scientific workers It is now, therefore, representative of France Great Britain, and the United States of America

THE Royal Horticultural Society is issuing invitations to the International Congress which the Society is arranging to be held in London on August 7–15, 1930, that is, immediately before the International Botanical Congress meets at Cambridge A representative executive committee has been appointed by the Society, with Lieut Col Durham, the secretary of the Society, as secretary, to whom the subscription for membership, one pound, should be paid The programme will include lectures and excursions, and a flower show on the last two days The main subject for discussion will be "Propagation vegetative and seminal", for which communications are invited and in which eminent British and Overseas authorities have already signified their intention of taking part There will also be other sections, and suggestions for papers for consideration are invited The six committees appointed at the Vienna Congress in 1927 will present their reports These include a Committee on Nomenclature, the report of which will be awaited with special interest in view of the lack of uniformity in the use of plant names, especially of varieties and hybrids, which exists at present among horticulturists Communications by means of papers, or participation in the general discussion, will be permissible in English, French, and German All correspondence should be addressed to the secretary of the Royal Horticultural Society, London, S W 1

THE first conversazione this year of the Royal Society will be held at the Society's rooms at Burlington House, W 1, on Wednesday next, May 15

UNDER the Order in Council dated Feb 6, 1928, the Lord President of the Council has appointed Sir James Alfred Ewing to be a member of the Advisory Council to the Committee of the Privy Council for

Scientific and Industrial Research, to fill a vacancy occasioned by the death of Mr Robert Whyte Reid

Sir James Irvine, Principal of the University of St Andrews, has been awarded the Elliott Cresson Gold Medal of the Franklin Institute of the State of Pennsylvania "for his brilliant research on Carbo hydrate Chemistry" The Medal will be presented on May 25, and will be accepted on behalf of Sir James Irvine by Sir Esmé Howard, British Ambassador to the United States

At the annual general meeting of the Society of Glass Technology, held in Sheffield on April 17, Mr Herbert Webb, of Stourbridge, was elected president in succession to Mr Walter Butterworth, Sen The following other officers were elected —*Vice Presidents* Mr E A Coad Pryor, Dr C J Peddle *General Treasurer* Mr Joseph Connolly, *American Treasurer* Mr F C Flint, *Hon Secretary* Prof W E S Turner

The council of the Institution of Civil Engineers has recently made the following awards in respect of papers read and discussed at the ordinary meetings during the session 1928–29 A Telford Gold Medal and a Telford Premium to Mr Conrad Gribble (London), a George Stephenson Gold Medal to Mr Harry Hall (London) Telford Premiums to Messrs H N Colam (London), F W A Handman (London), T P M Somers (Glasgow), H V C Johnstone (Sudan), and jointly to J H Hyde (Twickenham) and H R Lintern (Teddington)

The disastrous earthquake which occurred in Khorasan, Persia, on May 1, was recorded as a well marked disturbance at Kew Observatory The preliminary tremors reached the Observatory at 15 h 45 m 28 s G M T, and the records indicate that the epicentre was near lat 35° N, long 54° E The disturbance lasted about three hours, and the maxi mum displacement of the earth at Kew was nearly half a millimetre It is reported that a large area has been devastated and that great loss of life has occurred

It is announced in *Science* that the committee of the Academy of Natural Sciences of Philadelphia appointed to select a recipient for the Hayden Memorial Geo logical Award for 1929 has nominated Dr Charles Schuchert, professor emeritus of palæontology in Yale University, for the award, in recognition of his distin guished work in invertebrate palæontology, palæogeo graphy, historical geology, and the migration of faunas The Hayden Award was founded in 1888 by Mrs Emma W Hayden as a memorial to her husband, Dr Ferdinand V Hayden, director of the U S Geological and Geographical Survey in the early days of that organisation It consisted at first of a bronze medal with an honorarium in cash, but it now consists simply of a gold medal, and is given for pre eminent research in geology, palæontology, or in related sciences

His Majesty the King has approved the award of the Royal Medals of the Royal Geographical Society as follows Founder's Medal to Mr Francis Rennell Rodd for his journeys in Aïr and his studies of the Tuareg people, Patron's Medal to Mr C H Karius, assistant resident magistrate, Papua, for his crossing from the Fly River to the Sepik The Council has made the following awards Murchison Grant to Mr C S Elton for his three seasons' study of the distribution of life in Spitsbergen, Back Grant to Mr C P Visser for his exploration of the Hunza Karakoram glaciers, Cuthbert Peek Grant to Lieut Donald Cameron for his journey across the Sahara from Nigeria to Algiers, and Gill Memorial to Mr George Dyott for his recent expedition in search of Colonel Fawcett

With reference to the note in Nature of April 27, p 655, on the Huygens' object glasses presented to the Royal Society, it has been pointed out to us that Dr R T Gunther photographed the signatures "Constantine H", scratched on all three object glasses with their focal lengths, and published them in "Early Science in Oxford", vol 2, p 300, in 1923 The photographs show the bubbles in the glass of the lenses very clearly

The palæontological collections at Upsala have increased so enormously of recent years, thanks mainly to the receipt of the vertebrate material from China so thoroughly described by Prof C Wiman and his pupils, that it was necessary to store them in about half a dozen different buildings It is good news that the Swedish Riksdag has voted the sum of 791,000 kroner (about £44,000) for a new palæonto logical institute, in which research and teaching will be more conveniently carried on Building is to begin in the autumn

We have received the Annual Report of the Calcutta School of Tropical Medicine, Institute of Hygiene, and the Carmichael Hospital for Tropical Diseases, 1928 Administrative matters are very briefly dealt with, and the bulk of the publication consists of reports of the various departments with summaries of the research work carried out, much of which is of considerable value and importance

The Report of the Director General of Public Health, New South Wales, for the year 1927 has been recently issued In addition to statistical details, reports of scientific investigations are included As in former years, a large number of rats were examined for plague infection, but none was found In all, 220 samples of milk were examined for tubercule bacilli, and in no instance was evidence of tuberculosis found—an excellent record The year was notable for the very low incidence of typhoid fever, but diph theria has continued to be prevalent The death-rate from cancer increased, and has been increasing steadily for a number of years

Applications are invited for the following appoint ments, on or before the dates mentioned —A prin cipal of the York Technical Institute—The Secretary for Education, Education Offices, York (May 18) A junior technical officer in the Admiralty Technical Pool for duty in the experimental section of an Ad

miralty Establishment at Portsmouth—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (May 18) A head of the mathematics department of the Dundee Technical College and School of Art—The Secretary, Technical College, Dundee (May 20) A part time demonstrator in biology at King's College of Household and Social Science—The Secretary, King's College of Household and Social Science, Campden Hill Road, W 8 (May 22) A woman lecturer in geography at the Hull Municipal Training College—The Principal, Municipal Training College, Hull (May 22) Physicists and electrical engineers on the staff of the Radio Research Board of the Australian Commonwealth Council for Scientific Research—F L McDougall, Australia House, Strand, W C 2 (May 26) A horticulturist and an agricultural lecturer and warden at the Kent County Farm Institute at Borden—The Agricultural Organiser, Springfield, Maidstone (May 27) A principal of the Technical College and Junior Technical School, Horwich—J McLean, Railway Mechanics' Institute, Horwich, Lancashire (May 28) A lecturer in physiology at the Chelsea Polytechnic—The Principal, Chelsea Polytechnic, Manresa Road, S W 3 (May 31) A Government analyst for Cyprus—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 (May 31) A teacher in engineering at the Technical College, Wolverton—The Principal, Technical College, Wolverton, Bucks (June 1) A professor of commerce in the University of Birmingham—The Registrar, The University, Edgbaston, Birmingham (June 7) A professor of physiology in the University of Sydney—The Agent General for New South Wales, Australia House, Strand, W C 2 (June 8) A temporary junior assistant in botany in the University of Aberdeen—The Secretary, The University, Aberdeen A chief mathematical master at Whitgift Grammar School, Croydon—The Headmaster, Whitgift Grammar School, Croydon A woman lecturer in mathematics and geography at St Hild's Training College, Durham—The Principal, St Hild's Training College, Durham A tutor in psychology at Loughborough College—The Registrar, Loughborough College, Leicestershire An assistant in the public health laboratories and bacteriological department of the University of Durham College of Medicine—The Registrar, University of Durham College of Medicine, Newcastle upon Tyne

Our Astronomical Column

The Planet Mercury —This planet will be very favourably placed for observation at the middle of May as an evening star, being at its greatest elongation east of the sun on May 15, when it is placed twenty two degrees east of that luminary The planet will set on several nights more than two hours after the sun, and its position near the new moon on the night of May 10 will afford a very interesting spectacle in the west north west sky if the weather is clear On the date mentioned, Mercury will set at 9 46 P M G M T, and the moon goes down at 9 45 P M The sun sets at 7 33 P M, so that the phenomenon will be best seen at about 8 30 P M and may be watched until the two objects set Mercury will be situated to the north west of the moon about two degrees, and ought to be readily visible for about an hour to an observer who commands a good open view of the west north west sky in the region of the horizon The moon will appear as a very narrow crescent, but should be distinctly observable to the unassisted eye with Mercury in close attendance sparkling with a rosy light and looking more like a star than a planet

The Centre of the Galaxy —There are two papers on this subject in the March issue of *Proc U S Nat Acad Sci* Dr O Struve makes use of the conclusion that the strength of the calcium lines in early type stars ascribed to interstellar matter is a measure of their distance, the lines becoming stronger as this increases He has grouped the results for stars within 10° of the galaxy, taking means for every 30° of galactic longitude The results when plotted show a good approximation to a sine curve the maximum of which is in galactic longitude 337 6°, with a probable error of 18° The longitude is only 10½° greater than the value adopted by Shapley for the galactic centre Hence it strengthens the conclusion that the intensity of the spectral lines is a measure of distance, since the average distance is clearly a maximum towards the centre of the system of stars It should be noted that the galactic longitude is reckoned from the intersection (in Aquila) of the galaxy with the equator of 1900 Very few astronomers pay any attention to the resolution adopted at the meeting of the International Astronomical Union in 1925 that it should be reckoned from Alpha Cygni, with the view of getting rid of the correction for precession

Prof H Shapley's paper contains photographs and diagrams of the central region of the galaxy There are very brilliant star clouds to the south of the central line, but much dark matter along this line and to the north of it It is shown, however, that the dark clouds do not spread very far, and that there are transparent regions outside them where some spiral nebulæ have been photographed, which are evidently extra galactic The dark clouds may, however, conceal rich star clouds in the central region, also the mass of the obscuring matter itself is presumably large, so that it seems possible to imagine a sufficient amount of matter in the central region to account for the high velocities of revolution of the stars about this region which Oort, Plaskett, and others have found

The Distances of Dark Nebulæ —Series 2, No 52 of *Lund Meddelande* contains an investigation by W Gyllenberg of the distances of two regions where obscuration by dark matter is indicated by paucity of stars The method used is to make star counts in the obscured region and in a neighbouring unobscured one It is assumed that the dark nebulosity blots out entirely the light of stars behind it, assumptions are made as to the absolute magnitudes of the stars visible in the dark nebula based on general stellar statistics

Mr Gyllenberg applies his method to two regions The distance of the dark matter in the America nebula near ξ-Cygni is given as between 440 and 510 light years (Lundmark had previously found 610) The distance of the dark nebula near S Monocerotis is given as 250 light years in this case Lundmark had found a value 13 times as great Mr Gyllenberg confesses himself puzzled by this large difference He considers that if the colours or spectral types of the stars were considered, a much higher degree of accuracy could be attained

Research Items

Head Hunting.—In Vol. 58, Pt. 2 of the *Journal of the Royal Anthropological Institute*, Mr. J. H. Hutton analyses the head-hunting customs of the Nagas of Assam with the view of elucidating their significance both in that area and generally. Head-hunting has been explained as due either to a desire to obtain human hair for use as ornament or the desire for human beings to send to the next world as slaves of the dead. The latter belief, though present among the Nagas, is not found among the tribes where the practice of head-hunting was most flourishing. The religion of the Naga hill tribes centres on fertility cults, with which are connected phallic observances and the erection of menhirs. But though these observances secure fertility they are not its source. This seems to lie in the souls of the dead. A wooden figure which contained the soul of the dead used to be placed on a grave by the Angami. This was thrown away before the sowing of the millet crop. Among the Ao the smoke-dried body of a dead relative was kept in the house until the first fruits were eaten, after which it was disposed of in the usual way. Other customs of a similar character point to the association of the dead body with fertility through its preservation either until the sowing of the seed or until the first fruit ceremonies, when it was torn to pieces or otherwise treated. But among the peoples of Assam the head is more especially regarded as the seat of the soul. This is specifically stated among the Ao and may be inferred from the special sanctity of the head. A soul, for example, among the Konyaks may be transferred to a wooden figure by placing a skull upon it. If, therefore, the soul is a fertiliser and it resides especially in the head, when soul matter is required it may be obtained by cutting off a head and taking it home. Then not only enemies' heads are taken, but also the heads of comrades who fall in battle are cut off and brought back so that the enemy may not benefit by them. Women who hesitate to marry a man who has not taken a head may do so from the fear that he may be the less likely to be fertile. This form of belief seems also to underlie the head-hunting customs of Indonesia and the Pacific and may be traced westward and possibly as far as Britain and to neolithic or even palæolithic times.

Asymmetry and Cross-Breeding.—In an address to the Eugenics Society, delivered on April 24, Dr. C. J. Bond dealt with hemilateral asymmetry in animals and man and its relation to cross-breeding, and made a stimulating addition to biological thought. He concluded that hemilateral—and sometimes serial—asymmetry is closely associated with previous cross-breeding. He contrasted the ancient breeds of cattle, for example, *Bos primigenus* and *Bos longifrons* and others, the horns of which curved either upwards or downwards, with such modern cross-bred animals as the shorthorns, the horns of which frequently curve upwards on one side and downwards on the other. Similarly, heterodactyly in fowls is a frequent occurrence in the F^2 product of a cross; while in man there are cases of parents with different sized ear lobes producing children whose right ears resemble those of one parent and left ears those of the other. Other examples were derived from asymmetrical eye colour in man and animals. He argued that just as Mendelian segregation occurs in the formation of gametes, so in the cell differentiation of embryonic development, when the bilateral plan of growth is laid down, there is an analogous segregation of maternal and paternal genes. The degree of asymmetry appears to depend upon the closeness of kinship of the parents, whose physiological compatibility determines the stage at which segregation occurs. He hoped that the further study of this dissimilarity *in* the individual, like the study of dissimilarity *among* individuals, would assist genetic research.

British Heronries.—Although it is commonly believed that British heronries have declined during the past few centuries, there is no evidence of such decline in the statistics collected by E. M. Nicholson and his collaborators (*British Birds* for April). The number of heron's nests in England and Wales and part of Ireland in 1928 was between 3900 and 4000, but the English total was by far the greatest (3480 to 3566) not only in absolute numbers, but also in the average number of nests in a heronry, 14 there contrasting with about 7 in Wales and about 8 in Ireland. The highest averages occur in the south, Sussex leading with 54·55, followed by Dorset 38, and Essex 36, while at the other end of the scale lies Cumberland with an average of 6, and Northumberland with 6·7. Four English colonies had a total of a hundred or more nests. While in some places there have been marked declines, as at Aldershaw in Sussex, where there are said to have been 400 nests in 1840 and are now only about 80, taking the country as a whole the heron is holding its own or gaining slightly. The Scottish statistics have not yet been thoroughly collected and do not appear here, but will ultimately be published in the *Scottish Naturalist*.

Crustacean Feeding Mechanisms.—In continuation of their work on the feeding mechanisms of Crustacea, Prof. H. G. Cannon and Dr. S. M. Manton (*Trans. R. Soc. Edin.*, vol. 56, pt. 1, No. 9, 1929) have examined the three living genera of the Syncarida, *Anaspides*, *Paranaspides*, and *Koonunga*. They conclude that the first two genera exhibit two types of feeding, raptatory (*i.e.* grasping large food particles) and filtratory, essentially homologous with those previously described by these authors in *Hemimysis*. The third genus, *Koonunga*, and probably also *Bathynella*, have given up the filtratory method and feed only on large food masses. The Syncarida can thus be grouped in two series, *Anaspides* and *Paranaspides*; *Koonunga* and *Bathynella*, comparable with the Peracaridan series, Mysidacea; Isopoda or Amphipoda. Both series commence with forms exhibiting a filtratory mechanism, and through the development of the distal portions of the mouth parts and the suppression of the proximal filtering parts, end in a purely raptatory type. The raptatory mechanisms of *Anaspides* and *Paranaspides* have become modified for scraping up algal slime and similar bottom food by the enlargement of the basal portions of the first trunk limbs. The deviation of the feeding mechanism of *Koonunga* from the dual filtratory and raptatory type seems to have followed the same lines as the evolution of the typical amphipod or isopod type from that of the mysids. The maxilla has become an attenuated biting limb and lost all trace of endopodite and exopodite. The first trunk limbs have not formed a maxillipedal plate as in the higher Peracarida, but their heavy clawed armature and their marked flexure between the merus and carpus suggest that they are used for holding large food masses over the biting mouth parts. The most important characteristic of the *Koonunga* mechanism is the concentration of biting limbs, not around the mandibles at the mouth entrance, but around the distal endites of the maxillule.

GERMINATION OF *CYATHODIUM* SPORES —The liverwort *Cyathodium*, one of the Marchantiaceæ, for a time wrongly regarded as having a British representative (*Riccia spuria* Dicks), has recently been investigated by Mr N K Tiwary at Benares, secretary of Benares Hindoo University, who has sent to NATURE a communication on the subject Mr Tiwary has succeeded in finding an abundance of germinating spores, though it has not been possible to bring about germination artificially The spores are unusual in having from two to four germ pores, they appear to have a distinct polarity, for the germ tube and rhizoids arise from opposite ends, not from a single pore as is customary There is variation in the manner of germination, the cell contents on emerging from the germ pore form either an ovoid mass or a germ tube We have thus an addition to those species which have protonemata varying between the two main types

EARTHQUAKE IN THE ALEUTIAN DEEP —A great earthquake was registered at the Hawaiian Volcano Observatory (*Volcano Letter* for Mar 14) at 3 h 11 m 22 s P M on Mar 6 (1 h 41 m 22 s A M on Mar 7, G M T), the long waves being so prominent that the pens of the seismographs swept off the smoked paper From the duration of the preliminary tremors it was clear that the origin was about 3650 km from Kilauea This is the distance of the well known earthquake region that lies to the south of the Aleutian Islands, and later reports, received from Japanese vessels and elsewhere, show that the epicentre was on the north edge of the Aleutian Deep, a trough more than 4½ miles in depth, and about 100 miles south of Amukta Island About 7 45 P M, that is, in little more than 4½ hours later, the first sea waves reached Hawaii, the largest occurring between 8 and 9 P M The range of motion in Hilo Bay was, however, only 16 inches With the equally strong Alaskan earthquake of Feb 3, 1923, the sea waves at Hilo rose about 15 feet above the normal level

ECHO AND SCATTERING WITH SHORT WAVE RADIO TRANSMISSION —Radio engineers have been greatly puzzled by the anomalous results obtained when working with radio waves less than 100 metres in length Partial explanations of some of these results are given in a paper on short wave transmission read by T L Eckersley to the Institution of Electrical Engineers on April 10 The main interest in short wave transmission, both from the practical and theoretical points of view, lies in echo and scattering effects The author classes both these results together, as ultimately the two effects merge into one He regards the conducting 'layer' as a complex structure of scattering clouds, the scattering being more intense in the lower levels of the layer Experiments carried out near Chelmsford showed that local signals from Ongar could be balanced almost perfectly by means of a special receiver On the other hand, signals from Bodmin, Grimsby, the Dutch stations, and a Berlin station at night time (during the period of weak signals) could not be balanced by any adjustment of the circuits All these stations are within the 'skip' distance Long distance stations such as Canada, Australia, India, South Africa, Rio, Java, and many other distant beam stations give results which are intermediate between those obtained from near stations and more distant stations lying within the skip distance The author considers that the direct rays from the beam stations are so weak that their effects can be neglected The rays received at Chelmsford are those scattered back from the regions where the main transmitting beam penetrates into the scattering region of the conducting layer He now estimates the effective height of the daylight conducting layer as about 48 miles in summer and 60 miles in winter The scattering of short waves bears some resemblance to that of a searchlight playing upon the clouds If the searchlight itself is hidden from view, the point of intersection of the searchlight beam and the scattering clouds appears to be the source

A NEW THERAPEUTIC LAMP —Mr Albert Eidinow describes in the *British Medical Journal* of April 13 a new therapeutic lamp, the novelty of which lies in a closer imitation of the sun's spectrum Heliotherapy consists in the exposure of the patient's body to the sun's radiations, and to those from the sky, for carefully graded periods, which are increased up to several hours as the patient becomes accustomed to the treatment and as his body pigments he thus receives long combined doses of short infra red, intense visible light, and moderately intense 'long' ultra violet radiations between 3000 and 3200 A —the latter producing by slow degrees a deep, intense pigmentation Mercury vapour lamps and arc lamps all produce intense radiations in the ultra violet at wave lengths below 3000 A, to which patients can be exposed only for short periods without the production of intense erythemas The new lamp (Fig 1) is intended to give radiations more like those of the sun, and to this end a number of small metal filament glow lamps are used in series to supply visible light and heat in the yellow red part of the spectrum, while the necessary ultra violet component and the blue light are supplied by a long vacuum mercury vapour lamp tube, from which intense source all the short radiations are filtered out To effect this, the tube of the lamp is composed of frosted silica instead of fused quartz, and in addition, a screen of 'sanalux' glass, which cuts off most of the rays below 2900 A, can be interposed between the lamp and the patient To such a lamp patients may be exposed for several hours, either sitting up or recumbent, in the same way that they may be exposed to the sun in suitable climates, and so may obtain mild applications of long wave length ultra violet radiations together with the warming and stimulating heat and light from the glow lamps The lamp may be used for photographic purposes and for artificial daylight illumination, as for colour matching its light is almost indistinguishable from daylight

FIG 1

PHOTOGRAPHING ARTIFICIAL DISINTEGRATIONS —The practical difficulties which arise in the study of artificial disintegration by the Wilson cloud method are mostly connected with the necessity for taking a very large number of photographs Approximately

a hundred thousand normal α trails occur in nitrogen for every one in which disruption of a nucleus takes place, and it is therefore essential to work with recording devices of high efficiency In the issue of the *Proceedings of the Royal Society* for April 6, P M S Blackett has described a double camera for use with the large Wilson chamber made by the Cambridge Scientific Instrument Company, this takes two sharp photographs of the plane of the chamber on two mutually perpendicular films, a special feature in its design being that the principal plane of each camera lens passes through the line of intersection of the plane of the chamber with that of the corresponding photographic film Mr Blackett has made a detailed theoretical investigation of the optimum working conditions for this apparatus, and has shown that the magnification of the cameras should be reduced so far as possible towards the limit set by the resolving power of the photographic emulsions It is also found that if the number of tracks photographed in each beam of particles is made too large, there is a falling off in the observable number of resolved collisions Mr Blackett's paper is illustrated by two interesting plates, one of which shows the camera and Wilson chamber mounted ready for use, and the other some sheafs of α particles, many of which have secondary δ trails radiating from them

SOLID HELIUM —The issue of *Die Naturwissenschaften* for April 19 contains a short communication from the Physikalisch Chemisches Institut of the University of Berlin, by F Simon, announcing a further extension of the melting curve of helium It had previously been established that helium could be obtained in the solid state at as high a temperature as 20° abs by the application of a pressure of 1800 atmospheres, and in this new work the transition curve has been followed to 32° abs and 3500 atmospheres It is calculated from the data already obtained that it should be possible to solidify helium at the temperature of liquid air under a pressure of 15,000 atmospheres, provided no critical phenomena intervene As is pointed out, the fact that a substance can exist as a solid at a temperature that is very much higher than the highest temperature at which it can be held liquid when in the presence of vapour—5 2° absolute in the case of helium—may be of considerable significance in connexion with the state of matter in the interior of stars

RARE EARTHS FOR SPECTROSCOPY —Adam Hilger, Ltd , have now added a number of rare earths to the list of substances of exceptionally high purity which they can supply for spectroscopic and other purposes These have been specially prepared for them by Prof L Rolla and by Dr W Prandtl, and every specimen is guaranteed to contain in general not more than 0 1 per cent of total impurity The ceria and yttria which are now available have, in fact, been used in a similar state by Honigschmid and Auer von Welsbach for determinations of atomic weights, and the dysprosia is claimed to be even better than that used by these investigators Terbium, holmium, erbium, europium, florenzium, and thulium are also shortly to be placed on the market Considering the enormous labour involved in the isolation of these bodies, the prices asked for them are very moderate, ranging from only a half guinea for five grams of Rolla's lanthanum oxide to thirty pounds for a gram of Prandtl's dysprosia Messrs Hilger also possess a considerable number of scandium compounds which formed part of the collection of Sir William Crookes, which can be had either individually or in the form of mounted museum specimens

THE ASSAY OF COAL —In the examination of coal it is found useful to amplify analyses by distillation with measurement of the products so obtained Such methods give results differing from those of large scale practice, but, with experience, correlation is possible One of the many such tests proposed, the Gray King assay, devised at the Fuel Research Station, has been widely used, and in *Technical Paper* No 21 of the Fuel Research Board (London H M Stationery Office, 1s net), J G King, C Tasker, and L J Edgcombe record experiences with the test covering several years It is shown how the assay should be modified to deal with widely divergent materials

VAPOUR PRESSURES AND DENSITIES OF AMMONIUM CHLORIDE AND IODIDE —The determinations of the vapour pressures and densities of ammonium iodide and chloride made hitherto have shown considerable discrepancies Purcell and De Lange, whose results are described in the *Journal of the Chemical Society* for February, find that the vapour of ammonium iodide is completely dissociated at all temperatures up to 400° Their measurements, made between 300° and 400°, are in good agreement with those of Smith and Calvert The case of ammonium chloride has been investigated by Rodebush and Michalek, and details are given in the *Journal of the American Chemical Society* for March The vapour pressure of this salt appears to be unaffected by intensive drying, but the rates of vaporisation and condensation are considerably decreased The vapour was apparently completely dissociated even when the ammonium chloride had been dried for ten days at 60° in a vacuum

MAGNESIUM ZINC ALLOYS —The equilibrium diagram of this system has been re examined by W Hume Rothery and E O Rounsefell, and the results were presented at the March meeting of the Institute of Metals, the relations between the magnesium zinc and the magnesium cadmium diagrams were also discussed Both series contain analogous rather unstable compounds, $MgZn_2$ and $MgCd_3$, but whilst the Mg Cd system contains wide solid solution ranges in the parent metals, the Mg Zn system shows little solubility in the two metals, but forms two very unstable compounds, $MgZn_5$ and MgZn The evidence indicates that these exist in the solid state only and not as definite molecules in the liquid It would seem that some of the numerous unstable compounds met with in alloy systems may not correspond to any definite molecule in the chemist's sense of the word In these circumstances the following suggestions are put forward in connexion with primary solid solutions and compounds of fixed composition Where two metals form a stable compound there is usually considerable evolution of energy, and we may expect solid solutions to be almost entirely absent This condition is met with in most of the alloys of the electropositive metals with the border line metals, such as tin, antimony, bismuth, etc Where two metals form an unstable compound, primary solid solutions will be formed if the atomic volumes are nearly equal, as are those of magnesium and cadmium If, however, the atomic volumes differ widely, for example, zinc and magnesium, the tendency is for the main compound to be accompanied by other compounds which exist in equilibrium with the liquid over a very small range of temperature, and may exist only in the solid state representing the patterns into which the different sized atoms can be packed with or without chemical combination, that is, electron transference or sharing

The Permanently Frozen Soils of Russia

FOR more than two hundred years it has been known that in the extreme north of Siberia there are soils the lower strata of which are in a perpetually frozen condition. Since then a considerable literature on the problem has accumulated, but it is widely scattered, partly in almost inaccessible local publications, and a general critical survey of the literature, together with the results of original observations, recently published by the Far Eastern Geophysical Observatory in Vladivostok[1] is therefore of great interest.

The author defines these perpetually frozen soils as those the temperature of which is always below the freezing point, regardless of the presence or absence of water in the soil. This definition is more exact than most of the earlier ones, which have been usually based on the soil being cemented by frozen waters. It happens with some sufficiently loose and very dry soils that their particles remain free and the soil loose even after freezing; such soils nevertheless should be classified as permanently frozen.

The geographical distribution of such soils in Russia is at present fairly well known, though the information is still very fragmentary. As a matter of fact, there are 336 places where observations on permanently frozen soils have been made; of course, these observations vary widely in their scope and in their value. However, they are sufficient for a map to be prepared from them (Fig 1). The whole area of permanently frozen soils in Russia occupies about 7 000 000 sq km, that is, very nearly one third of the whole territory of Russia, and a little less than the area of Europe, and about the same as the area of the United States or of the whole continent of Australia. The southern boundary of permanently frozen soils is, as will be seen from the map, very irregular; in European Russia it begins at the White Sea shores and runs eastwards almost parallel to the Arctic Circle and a little south of it up to Turukhansk in Siberia, where it turns sharply south eastwards until it reaches latitude 50° N; its course beyond the latter is not known, being outside Russian territory in Mongolia; near Blagoveshchensk and Khabarovsk the southern boundary of the permanently frozen soils again enters Russia, running in a north easterly direction to the northern part of Kamtchatka about latitude 60° N.

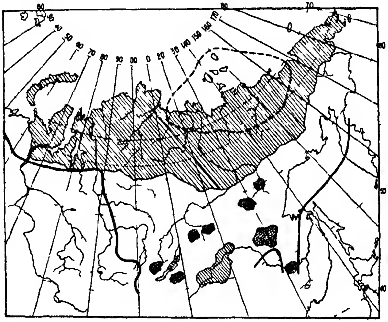

FIG 1.—Diagrammatic map of permanently frozen soils of Russia (re drawn after Soumgin). Oblique lines—continuous areas of permanently frozen soils; oblique lines and dots—areas of permanently frozen soils with islands of normal soils; crossed lines—areas of normal soils with islands of permanently frozen soils; heavy continuous black line—southern limit of permanently frozen soils; heavy interrupted black line—the boundary of the area where considerable strata of solid ice are present in the soil.

Inside this enormous region of permanently frozen soils several areas may be distinguished. Thus a very large continuous area of permanently frozen soils occupies the whole extreme north of Siberia along the shores of the Polar Sea; another compact area is situated in Transbaikalia; in the rest of the region islands of permanently frozen soils are scattered.

The depths to which soils may be in the permanently frozen condition were determined in a number of cases and fluctuate from 36 3 m in Pustozersk to 74 68 m in Taldan, Amur province, and even to 116 4 m in Yakutsk; in the latter case the actual depth has not been determined, since non frozen strata has not been reached. Detailed observations on the temperature conditions of these soils are still very inadequate. Middendorf in 1848 made some determinations of temperatures in a shaft at Yakutsk and found that the temperature decreased with the depth, reaching 3 C at 382 ft below the surface; a constant annual temperature was found at 100 ft deep. From these figures Middendorf determined the lower limit of the permanently frozen soil in Yakutsk at about 600 ft below the surface, but all his observations are somewhat doubtful as to exactitude. Much more thorough studies in this respect were made recently at Bomnak, Amur province, but they were restricted to relatively small depths not exceeding 5 m. The upper limit of permanently frozen soil at Bomnak was found to be at 2 8 m from the surface.

During the ten years of observations at Bomnak a correlation has been observed between the thickness of snow and the seasonal fluctuations of the temperature of the soil. In years when snow fell late and was not very thick, the temperature was found to increase with the depth, while in winters with abundant snow it protects the soil from cold and the temperature of the soil decreases with the depth, monthly maxima and minima of temperatures in the soil at 1 5 metres deep lagging two months behind the air temperatures. When the upper layers of the soil freeze or thaw, the water contained in them gives up, or absorbs, respectively, the heat energy, thus

[1] Everfrozen of Soil in the Boundaries of U S S R by M Soumgin Pp 372 The Far Eastern Geophysical Observatory Vladivostok 1927

interfering with the distribution of temperatures in the soil In this way a 'zero curtain' in the soil is formed which is of the greatest importance for the temperature regime of the soil, this 'zero curtain' does not lie at a constant depth, but moves up or down, according to the air temperature The amplitudes of the monthly mean temperatures at depths exceeding one metre are very small and rapidly decrease with the depth Observations in other places lead to the conclusion that three different types of the distribution of temperatures in permanently frozen soils may be distinguished, namely (1) temperature increases with the depth, (2) temperature decreases with the depth, (3) temperature decreases down to a certain depth, then increases The distribution of temperatures at greater depths has not been studied since Middendorf's work, but it may be safely assumed that it is very complicated

As regards the origin of permanently frozen soils, many authors consider them to be the result of the present climate, but Soumgin believes that they have remained frozen since the glacial period

A special chapter of the book is devoted to the study of hydrological conditions in the region of permanently frozen soils, while other chapters deal at some length with the influence of the frozen soils on the surface features, especially the distribution of forest types, and with the practical difficulties in building and other engineering work on frozen soils

An elaborate programme of studies on permanently frozen soils is put forward by the author, who concludes his interesting monograph with a somewhat startling project for establishing somewhere in the area of permanently frozen soils a refrigerator museum, where bodies of various animals and men should be deposited in order to be examined and compared with later types after several thousands of years

Fisheries of Madras

VALUABLE work by the Madras Fisheries Department is described in the administration report for the year 1926–27 by the Director, Dr B Sundara Raj (Madras Fisheries Bulletin, vol 22, pp 1 99 Madras 1 rupee 1928) The report deals mainly with the commercial development of the department as applied to fish, pearl, and chank fisheries

The Chaliyam Fish Cannery, which was expected to recommence its manufacture during this period, did not operate, as Sir F A Nicholson was prevented from undertaking the management of the experimental and manufacturing operations, due to ill health Yet it is hoped that the cannery will be continued, as it has not been given a chance to prove the commercial possibilities of canning as a remunerative industry, especially as two private canneries started on the model of the one at Chaliyam had not prospered At Tanur, researches were continued on the methods of preserving fish in a fresh condition for sale in the interior markets, of curing, pickling, and tinning bonito, cat fish, and others for disposal in Japan and other places abroad and of preparing fish oil from the liver of sardines The initial experiments carried out with sodium hypochlorite as a preservative of fish in a fresh condition have shown "that about 200 c c of solution (with 1 per cent available chlorine) is sufficient to keep 1 lb of smaller varieties of fish for over 30 hours" Fish meal, with a low fat content, was made from chamban (*Caranx crumenopthalmus*), and shrimp by the use of a press more powerful than a hand press

Investigations for improving the resources of edible fish in inland waters were continued Despite adverse seasonal conditions, the experiments at Vellore and Chingleput Fort Moat Farms demonstrated the utility of stocking catla The catla fry from the Godavari channel grew to a length of 1½ to 2 feet in eight months in these farms For want of material the Hilsa hatching experiments have not been satisfactorily concluded, the gourami (*Osphromenus sp*), the tench, and the carp have flourished in inland waters Experiments are being conducted on the trawling grounds close to the Madras coast to ascertain the possibilities of deep sea fishing

In the whole history of Ceylon and Indian pearl fisheries, no more than a single fishery was considered possible in any year For the first time, a fishery was commenced in the autumn of 1926 on Nov 6 and lasted until Dec 4 This small fishery brought a net profit of Rs 26,801 Another fishery, which excelled all previous fisheries in its excellent organisation of the camp and in the operations at sea, was opened on Feb 11 and closed on April 30 The time honoured method of fishing and disposing of the oysters was in vogue, except for the fact that the lots of 500 each were counted at sea on board the depot schooners, to avoid extra wages to the labourers and to minimise the pilfering of pearls by divers on their way back to the shore from the banks Although the usual difficulties which marred the administration of the pearl fisheries in the past, such as wrong locations of banks, epidemics, etc, were circumvented, other adverse factors, such as bad weather, depreciation of the market value of pearls, etc, contributed towards a lower yield of revenue than was anticipated Yet this fishery ranks first among those held within the last hundred years, and the Government realised a net profit of Rs 172,316 Owing to the pearl fisheries, the chank fisheries suffered a set back, and only a fourth of the normal catch in a good year was fished It is interesting to note that steps are being taken to develop the ancient chank bangle industry, and that the initial difficulty in the development of this industry has been overcome

The marine aquarium continued to be popular The researches on the development of the edible oyster (*Ostrea madrasensis*), carried out in the laboratory of the aquarium, revealed the fact that the Indian oysters fatten and breed only in low salinities, whereas the English oysters flourish when there is a rise in salinity The tiles put out at Ennur to collect oyster spat were attacked in such large numbers by a molluscan pest (*Modiola sp*) that it is proposed to abandon oyster culture in this locality It is proposed that, if the Marine Biological Station at Krusadai Island is established, its immediate lines of inquiry should be (1) Biological investigations with special reference to pearl and chank fisheries, (2) hydrographic and meteorological investigations, and (3) technical and industrial researches with special reference to fishing methods Further, it is suggested that the following laboratories, aquaria, etc, are required to start the proposed lines of research (1) The establishment of three new research laboratories, in addition to the one at Calicut, with adequate facilities, (2) the construction of aquaria at Rameswaram and at Vizagapatam, and (3) the establishment of a bio chemical laboratory equipped with requisite apparatus and staff to deal with the technology of fishery industries It is very gratifying to note that the Fisheries Department has continued with success the introduction of elementary education to children of the fishing population, the organisation of the co operative movement on a wide scale, and the promotion of temperance and other social benefits to the community

New Rubber Plant from Madagascar

DR CHARLES F SWINGLE of the U S Department of Agriculture was working in the Department of Botany of the University of Leeds during the winter of 1927 28 making a study of the vegetative propagation of plants from the anatomical point of view A problem of practical plant propagation then arose through the decision of the U S Department of Agriculture to try to introduce the rubber plant *Euphorbia intisy* from Madagascar into the United States Dr Swingle sailed from England at the end of May 1928 joining Prof Henri Humbert of the University of Algiers in a collecting expedition in the uplands of Madagascar and a statement of the results obtained has been issued by Science Service of Washington D C

Euphorbia intisy grows to be a small tree some of the largest specimens seen by Dr Swingle being about 12 ft high and 5 in in trunk diameter although trees 20 ft high with a diameter of about 1 ft are reported As a rubber plant it is remarkable for the ease with which the rubber can be collected It separates itself from the latex on exposure to air no elaborate coagulation or smoking process being necessary Years ago when the natives of Madagascar were collecting rubber for the French they would simply cut long gashes in the bark of the tree and then go round next morning and peel out strips of rubber Unfortunately this primitive collecting took place in a time of high rubber prices with the result that the tree was almost exterminated Outside Madagascar the species seems to be practically unknown and there is probably not another living plant outside the island apart from the specimens now growing in a locked greenhouse in Washington

These plants will probably provide a very considerable practical problem in vegetative propagation The species can be propagated from stem cuttings but it is of slow growth and years will be required before the stock in the United States can be increased to a point where commercial experiments can be undertaken Probably its peculiar habit of growth is responsible for the fact that the plant has survived its exploitation in its native haunts in Madagascar According to Dr Swingle the root system consists of chains of tuberous thickenings strung together after the fashion of sausages These tubers are storage organs for water enabling the plant to survive in the desert through a drought as long as six rainless years With this system of underground life assurance the remnants of the rubber forest were able to survive the massacre and to begin life over again after the activities of the rubber hunters had ceased

University and Educational Intelligence

CAMBRIDGE —The President of the Committee of the Privy Council for Scientific and Industrial Research has approved the application for a grant of £1500 to the University for the erection of the liquid hydrogen plant at the magnetic laboratory

The following grants have been made from the Worts Fund £100 to the Zoological Station at Naples £40 to H G Watkins and J M Scott towards the expenses of a surveying expedition in Labrador £50 to Miss S M Manton for researches on the fauna of the Great Barrier Reef, £15 to Dr H Hamshaw Thomas towards the expenses of a fossil collecting journey in South Africa A grant of £25 has been made from the Balfour Fund to J T Saunders for investigations on the hydrobiology of the Swiss Lakes

A Denman Baynes Scholarship at Clare College for research in mathematics physics or chemistry of the annual value of £100 will be awarded in July Preference will be given to graduates of the University of Cambridge and *ceteris paribus* to members of Clare College Applications should be sent to the tutor of Clare College on or before July 1 with such evidence of qualifications as candidates think fit to submit and a statement if possible of the proposed course of research

LEEDS The degree of D Sc has been conferred on Mr H C Versey for a thesis entitled Studies in the Tectonics of the North of England

LONDON The following courses of free public lectures are announced The Photo electric and Photo chemical Measurement of Light with Biological Applications by Dr W R G Atkins at the Imperial College of Science (Royal School of Mines) on May 14 15 and 16 at 5 30 The Physiology of Glycogen by Prof J J R MacLeod at the London Hospital Medical College on May 16 and 17 at 5 30 and Sweden and the North of Europe by Prof Sten de Geer at Birkbeck College on May 24 28 and 30 at 5 30

Applications are invited for the University Studentship in physiology value £100 Applications must reach the Academic Registrar of the University South Kensington S W 7 by May 31 at latest

The first annual memorial lecture instituted in memory of Lord Haldane late president of Birkbeck College will be given at Birkbeck College by Lord Justice Sankey on Tuesday May 14 at 5 30 P M the subject being Lord Haldane s Life and the Adult Education Movement The Earl of Lytton will preside

MANCHESTER —Applications are invited for the Sir Clement Royds memorial scholarship in chemistry of the value of £300 The scholarship is for the encouragement of advanced study and research in chemistry in the faculty of science of the University and is open to British subjects of British descent born in or inhabitants of the County of Lancaster preference being given to the county borough of Rochdale The latest date for the receipt of applications which should be sent to the Registrar is June 1

Applications are invited for the Dr Robert Angus Smith scholarship value not exceeding £150 the object of which is the encouragement of research in sanitary science Applications must reach the Registrar of the University by June 1

THE Ramsay Memorial Fellowship Trustees will consider at the end of June applications for a British Fellowship for chemical research The value of the Fellowship will be £250 per annum to which may be added a grant for expenses not exceeding £50 per annum Particulars as to the conditions of the award are obtainable from the Secretary of the Ramsay Memorial Fellowships Trust University College London (Gower Street W C 1)

VACATION Courses at Leyden Holland in August in glass blowing and instrument making have been arranged for by the Society for the Advancement of the Training of Instrument Makers Particulars of the courses may be obtained from Dr C A Crommelin Physical (Cryogenic) Laboratory the University Leyden to whom applications should be sent before June 8

ON Jan 1 the Rockefeller Foundation took over the work in Europe which was previously under the administration of the International Education Board Dr Lauder W Jones of Princeton University has been

appointed associate director for the natural sciences of the Rockefeller Foundation Dr Jones assumed his duties at the beginning of April and will have his headquarters in Paris, carrying on the work as successor to Dr Augustus Trowbridge

The Salters' Institute of Industrial Chemistry is again offering a limited number of fellowships to chemists of post graduate standing, the object being to afford additional and special training at home and abroad, preparatory to a career in industrial chemistry The value of each fellowship will be from £250 to £300, and applications must reach the director of the Institute, Salters' Hall, St Swithin's Lane, E C 4, not later than June 1 The Salters' Institute will in July allocate a limited number of grants in aid to young men and women employed in chemical works in or near London who desire to extend their education for a career in chemical industry The latest date for the receipt of applications is June 7

A number of studentships — 'research' and 'advanced study'—not exceeding ten in all, are being offered by the Empire Cotton Growing Corporation for the purpose of (a) enabling graduates who believe that they have a leaning towards research to equip themselves for posts in which work of that type is required, and (b) enabling men to receive such specialised instruction as their previous qualifications and experience show to be most desirable in order to equip them for agricultural posts in cotton growing countries wherever opportunities for employment may present themselves The value of each studentship is £250 a year, with certain additional allowances for travelling expenses, books, etc. Forms of application can be obtained from the Secretary, Empire Cotton Growing Corporation, Millbank House, 2 Wood Street, Millbank, S W 1 The latest date for the return of forms is June 4

The Colston Research Society, which exists to assist research work in the University of Bristol by means of money collected annually, has received this year, in addition to the ordinary collection, the sum of £5000 from one of the Society's oldest subscribers, Mr R H Mardon The money is to be maintained intact to provide a fund annually for investigation in agriculture or industry in the University of Bristol which is likely to be of benefit to any portion of the British Empire This is the first permanent endowment which has been received The Colston Research Society was founded thirty years ago, and of recent years has collected annually £700 to £800 Mr Mardon's gift encourages the hope that further endowments may be forthcoming

The Rockefeller Medical Fellowships for the academic year 1929–30 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1 These fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation and are awarded to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles In special circumstances the fellowships may be tenable at centres of research not in America A fellowship held in America will have the value of not less than £350 a year for a single fellow, travelling expenses and some other allowances will also be paid Forms of application are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1

Calendar of Patent Records.

May 14, 1655 —The patent granted to Sir Edward Ford on May 14, 1655, for his method of "drayning of lands, raysing of water to serve citties or houses, as likewise for cleering, drayning, and avoiding of springs from mynes and quarries" is the only one to be found on the Commonwealth patent rolls Ford erected pumps, worked by a horse gin, on a site between Somerset House and Arundel House, opposite the present Surrey Street, for supplying water to London direct from the Thames The pumps remained working for several years, but were ordered to be pulled down by Charles II because "the great fabric of wood" was a nuisance, especially to Denmark House, the residence of Queen Henrietta Maria

May 14, 1825 —Sir Goldsworthy Gurney's steam road carriage, which he patented on May 14, 1825, was provided, in addition to the ordinary piston engine driving the wheels, with adjustable propelling legs which acted successively against the surface of the road to assist the coach up hills A contemporary drawing shows that it was a six wheeled vehicle

May 15, 1824 —The machine for making solid headed pins which was the subject of the English patent granted to the American, Lemuel Wellman Wright (on behalf of a kinsman in the United States), on May 15, 1824, was not the first of its kind to be patented, but was the first to achieve commercial success, though it was many years before pins made by the old process dropped out of the market The manufacture started by the inventor in London failed, but the patent was acquired by Messrs Taylor and Co, of Stroud, Gloucestershire, who spent a large sum of money in perfecting the machine The life of the patent was extended for five years by the Privy Council

May 15, 1832 —The steam plough with stationary engine and cable was patented by John Heathcoat on May 15, 1832 The patent foreshadowed also the use of 'caterpillar' wheels for agricultural machinery To enable the apparatus to be worked on soft ground, the engine was fixed on a carriage of large dimensions and mounted on a series of wheels which conducted "an endless flexible floor, railroad, or way," within and upon which the carriage was caused to travel The 'flexible floor' was made of painted or tarred sail cloth stretched on strips of metal

May 15, 1844 —The first industrial application of gutta percha was in the manufacture of cork stoppers and other articles, and was patented by Charles Hancock on May 15, 1844 The new material only became known in England the previous year, when specimens of it were exhibited for the first time at the Society of Arts

May 16, 1674 —The patent granted for seven years to George Ravenscroft on May 16, 1674, for "his new invention or art and manufacture of a certaine christeline glasse resembling rock christall not formerly used in this kingdome" was a landmark in the history of English glass From it dates the introduction of the flint glass industry of England which dominated the European markets for many years

May 16, 1862 —The bicycle did not become popular until about 1865, when Ernest Michaux of Paris introduced what became generally known as the 'boneshaker,' which had pedals fitted directly to an enlarged front wheel But a notable contribution to its success as a means of transport was made by Albert Louis Thirion, a Belgian resident in London, who on May 16, 1862, was granted in England the first patent for roller or ball bearings for use on velocipedes.

Societies and Academies

LONDON

Royal Society, May 2 — **J S Haldane, W Hancock, and A G R Whitehouse** The loss of water and salts through the skin, and the corresponding physiological adjustments The paper contains data as to the nature and percentage amounts of salts lost from the skin without sweating and in different stages of free sweating The disturbance produced when loss of salts and water is replaced by gain of pure water is ordinarily prevented by the compensatory action of the kidneys and a natural craving for salt What is kept practically constant is the diffusion pressure of water within the body, in accordance with Claude Bernard's conception of the blood as an internal environment maintained constant by the co ordinated action of organs —**F H A Marshall and J Hammond** Œstrus and pseudo pregnancy in the ferret 'Heat' is prolonged in absence of coitus The vulva enlarges to about fifty times its anœstrous size and persists to cessation of heat Ovulation occurs at any time during heat, but only after coitus Details are given of the uterine changes All changes are apparently controlled by the corpus luteum The vulva affords no external indication of the luteal phase which is the main factor in the developmental changes – **R G Canti and F G Spear** The effect of gamma irradiation on cell division in tissue culture *in vitro* The fall in the number of cells undergoing mitosis was followed by a rise which, with a certain exposure and intensity, was com pensatory to the fall With longer exposures, though there was a tendency to rise, the number of cells undergoing mitosis never reached the normal —**R B Bourdillon, C Fischmann, R G C Jenkins, and T A Webster** The absorption spectrum of vitamin D By the action of ultra violet radiation on ergosterol three substances (or groups of substances) are produced in succession The first shows an absorption band roughly similar to that of ergosterol (maximum 280$m\mu$), but more than twice as intense, and has great anti rachitic activity It is probably vitamin D Neither the second nor the third substance has antirachitic activity, though the former shows a strong absorption band at 240$m\mu$ The actual percentage of vitamin D present in the purest preparations studied is estimated as above 50 —**G E Briggs**. Experimental researches on vegetable assimilation and respiration (20) — **R J Lythgoe and K Tansley** The relation of the critical frequency of flicker to the adaptation of the eye The critical frequency due to the cones falls during dark adaptation and with decreasing levels of light adaptation and is highest with equally bright surrounds That due to the rods behaves in the opposite fashion The peripheral cones are function ally not identical with the foveal cones The bright ness of the surrounds is the most important factor in determining whether the critical frequency relations are of the rod or cone type, bright surrounds en couraging the cones and dark surrounds the rods — **R Hill** Reduced hæmatin and hæmochromogen — **G R. de Beer** The development of the skull of the shrew —**J W Pickering** The influence of Witte's 'peptone', and of digestion on blood platelets and plasma —**F W R Brambell and A S Parkes** Com pensatory hypertrophy of the untreated ovary after unilateral X ray sterilisation —**W Moppett** The differential action of X rays in relation to biology, chemistry, and physics (Part 1) —**C H Browning, J. B Cohen, S. Ellingworth, and R Gulbransen** The trypanocidal action of some derivatives of anil and styryl quinoline

PARIS

Academy of Sciences, April 8 —**P Villard** The devitrification of glass Experiments are described leading to the conclusion that devitrification of glass is the consequence of a loss of sodium or potassium, and practical suggestions are made for working glass before the blowpipe so as to reduce devitrification to a minimum —**G Vranceanu** The three points of view in the study of non holonome spaces —**Georges Giraud** The solution of the problem of Dirichlet for linear equations – **Krawtchouk** The approximate solution of linear integral equations —**Mlle Nina Bary** Some mixed forms of the finite representation of an arbitrary continuous function —**J A Lappo-Dani-levski** Fundamental problem of the theory of functions in the class of matrices satisfying systems of differential equations with rational coefficients — **Benjamin Meisel** The approximate definition of the relative kinetic energy of a liquid filling a rotated vase —**E Sevin** The Compton effect and its inverse — **Antoine Willemart** The absorption spectra of the rubrenes Curves are given of the absorption spectra of the three known rubrenes, rubrene, dimethyl rubrene, and bibenzorubrene Each has the same number of bands similarly placed, and the three maxima on each curve have identical wave lengths — **H Damianovich and J J Trillat** Researches on the action of helium on platinum Under the influence of an electric discharge at low pressure, platinum re tains large quantities of helium Examination of the substance produced by means of the X rays, using the Debye Sherrer method, did not give very definite re sults, but there were some indications of the presence of a new micro crystalline compound probably a combination of helium and platinum – **Galibourg** The effect of extension and ageing on the elastic limit of metals —**J Cournot** The influence of the dimen sions of the test pieces in measurements of the vis cosity of metallurgical products The dimensions of the test piece have a marked influence on the flow of the metal the practical limit of the viscosity in creases with the diameter of the test piece Data are given for aluminium wires —**Lespieau and Wiemann** The preparation of acetylenic hydrocarbons with the aid of epidibromhydrins Details of the products of the reaction between methyl magnesium bromide and the epidibromhydrin containing five atoms of carbon —**V Agafonoff** The determination of the mass of carbon and constitutional water contained in the soils of the terrestrial globe —**Henry Hubert** The monthly rainfall curves at Madagascar —**Guilliermond** New remarks on the Golgi apparatus the Golgi apparatus in the yeasts Additional proofs, with illustrations, are given of the author's view that there exists no Golgi apparatus independent of the chondriome and the vacuome —**L Marrassé** Hexamethylenetetra mine and formaldehyde are true foods for the bean The conclusions of E and G Nicolas, based on the method of cultures, are confirmed by a cytophysio logical method hexamethylenetetramine and formal-dehyde, in proportions of 0 2 per thousand of the former and 0 16 per thousand of the latter, form true foods for the cells of the bean —**I D Strelnikov** The fauna of the Sea of Kara and its ecological conditions – **G Frank and M Popoff** The mitogenetic radiation of the muscle in contraction The mitogenetic radia tion can only be the product of the explosive glycolysis which occurs precisely at the period of latent irrita tion and at the commencement of the contraction — **P Delanoë** The presence of the *Ornithodorus* of Morocco in the burrows of porcupines and foxes and in human habitations Its existence in eastern Morocco Frequency of a recurrent spirochæte in the *Ornitho-dorus* of these burrows

GENEVA

Society of Physics and Natural History, Feb 21 — **E Cherbuliez and P Plattner** A new method of separation of the amino acids in the form of their acetyl esters The principles of this separation are as follows (1) hydrolysis by hydrochloric or sulphuric acid at the boiling point, (2) esterification of this solution by alcoholic hydrochloric acid, (3) acetylation of the syrup obtained by concentrating the solution of the hydrochlorides of the esters by treatment with acetic anhydride and sodium acetate in excess —**E Cherbuliez and S Ariel** A new method of disintegrating the proteids and the problem of the size of the molecules of the scleroproteins The authors have studied the solubility of the following scleroproteins in acetamide at 200° C and in urea at 140° C fibroin, keratin (dog's hair, ox hair), elastin (ox) The latter is insoluble in both solvents at the temperatures given above, the keratins are both soluble, the fibroin soluble in urea and partially soluble in acetamide (28 per cent in 30 minutes) The process of solution is accompanied by a profound modification of the chemical character of the proteids utilised, and this is probably due to an intramolecular transposition —**G Dejardin** The progress realised in the preparation and use of thermionic cathodes The author describes particularly the cathodes consisting of a metallic nucleus with a superficial layer, probably monatomic, of another metal The cathode nucleus is a tungsten wire covered superficially with an oxide, such as copper oxide, susceptible of being reduced by barium vapour at a moderately high temperature The barium salt of hydrazoic acid, BaN_6 is utilised —**R Chodat** The theory of generalised mutation and mutations in *Chlorella rubescens* By cultures derived from a single cell, carried out with the micromanipulator of Janse and Peterfi, the author ascertains from several generations that the general law is not constancy but micromutation In the colonies, the micromutants are, as it were, merged in the whole and escape observation —**Arnold Pictet** The reconstitution of a dominant character by crossings between recessives —**Ed Parejas** Geological observations in Corsica (2) The autochtone sediment of Popolasca At Popolasca, the Mesozoic presents facies comparable with those of Malm and of the Helvetian Infravalanginian (autochtone of Gastern and Doldenhorn stratum) One of these limestones contains authigen albite A thin layer of granite not hitherto pointed out overlaps the series of Popolasca —**G Tiercy** Concerning the gain and loss of chronometers (2) To the considerations developed in an earlier note, where the author gives the relation correction = -(rate) he adds some further remarks taken from the meaning attributed to the word 'etat' in finance and in rational mechanics He stresses the fact that the word 'etat' (rate) is employed in relation to watches, not only at the Geneva Observatory but also at Kew and at Besançon

ROME

Royal National Academy of the Lincei, Jan 20 — **F Severi and B Segre** Further with regard to a topological paradox (2) —**G Giorgi and Ernesta Porcu-Tortrini** Motions of deformation in space represented by means of matrix calculus —**U Cisotti** The triple tensor of Christoffel —**F Zambonini and Silvia Restaino** Double sulphates of the rare earth and alkali metals (12) Cerous and cæsium sulphates Study of the isotherm of the system, $Ce_2(SO_4)_3$ – Cs_2SO_4 – H_2O, at 25° indicates the existence of the compound $Ce_2(SO_4)_3$, Cs_2SO_4, $8H_2O$, which is stable within moderately wide limits —**S Franchi**: Non existence of the great faults known as the Monte Rosa bowl and of the Great St Bernard bowl in the Western Alps Study of the tectonics of the Franco Italian Cottian Alps indicates that the Monte Rosa bowl (V) and the Great St Bernard bowl (IV) have no real existence, and that, in the western Alps, the contact between the permian, attributed to fold IV, and the calc schisto, attributed to V, is a normal contact —**B Segre** Construction of a simple oblique Jordan's curve —**A Mambriani** A particular differential equation Scorza Dragoni has recently indicated briefly the method, to be published fully later, used to demonstrate the existence and unicity of the solution of the differential equation, $y'' = yt\ x^{-\frac{1}{2}}$, with the limiting conditions $y(0) = 1$, $y(+\infty) = 0$, which arises from certain physical investigations of Fermi It is now shown that the existence and unicity of the equation in question may be deduced at once from classical propositions on ordinary differential equations, in conjunction with elementary observations on the particular form of the equation —**Rita Liceni** The form F_2 of Fubini For the surfaces in a four dimensional space S_4, Fubini found a form indicated by him by F_2 which has a projective character Later, in the study of certain varieties, Vitali encountered a form F_2, also of projective character, and showed that, in the case of the surfaces in S_4, his F_2 coincides with that of Fubini The author now develops the analytical passage from one form to the other —**J Kaucký** Sur faces of which a canonical straight line passes through a fixed point —**F Cecioni** Conform representation of pluri-connected areas belonging to a Riemannian surface —**A M Bedarida** Systems of arithmetical progressions —**G Krall** Upper limitations for the dynamic displacement in elastic systems Higher limits are assigned to the displacement of an elastic body, vibrating under the action of either constant or time variable forces, starting from the more general initial circumstances of the motion —**A Carrelli** The new diffusion phenomenon the Raman effect It is shown that, as for Tyndall light, the intensity of Raman light is directly proportional to the fourth power of the emitted frequency and is dependent also on magnitudes characteristic of the lines in the dispersion formula of the substance considered —**T G Levi** Dithioformic acid (2) Various derivatives of dithioformic acid, obtained by the action of chloroform on potassium sulphide The acid, now isolated in the pure form as a white solid melting and decomposing at 55° 60°, decomposes into hydrogen sulphide, carbon disulphide, carbon, and sulphur, when heated The results of molecular weight determinations indicate that the acid and its esters exist as trimerides, and a cyclic structure with alternate carbon and sulphur atoms is suggested Two isomeric benzyl esters exist, the isomerism being probably of the cis trans type —**F Rodolico** Crystallographic investigations on cinnabar from Idria

VIENNA

Academy of Sciences, Feb 21 —**E Beutel and A Kutzlnigg** The action of potassium ferrocyanide on silver and some slightly soluble silver compounds —**W Leithe** The natural rotation of polarised light by optically active bases (2) The rotation of *d* α-phenyl ethyl amine and its chlorhydrate in solution, with remarks on the rotation of active tetra-hydroquinaldine —**E Haschek** A contribution to the theory of photochemical phenomena Concerning the retina of the eye —**K. Schnarf** The embryology of Liliaceæ and its systematic significance —**M Holly** Three new fish forms from Persia *Barbus* and others, including a cyprinodon from warm springs.

Diary of Societies

FRIDAY MAY 10

ROYAL ASTRONOMICAL SOCIETY at 5 — Prof E Hertzsprung The Pleiades (George Darwin Lecture) —E A. Kreiken On the Dwarf Nature of Double Stars

PHYSICAL SOCIETY (at Imperial College of Science) at 5 —Dr W E Sumpner Heaviside s Fractional Differentiator —J H Awbery A Simple Method of Fitting a Straight Line to a Series of Observations.—E W H Selwyn Arc Spectra in the Region λ1600–λ2100 —Dr K R Rao The Spectrum of Trebly ionised Thallium —G A Wedgwood The Elastic Properties of Thick Cylindrical Shells under Internal Pressure —A Demonstration relating to Standards of Length and Mass by J E Sears

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (at Abbey Hotel Kenilworth) at 5 30 —Discussion on Stare Bridge D H Brown Kenilworth Castle and Town S Douglas

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30 —Annual General Meeting

MALACOLOGICAL SOCIETY OF LONDON (in Zoological Department, University College) at 6

INSTITUTION OF MECHANICAL ENGINEERS at 6 —Special General Meeting

ROYAL SOCIETY OF ARTS (Indian Meeting), at 8 —Captain P Johnston Saint An Outline of the History of Medicine in India (Sir George Birdwood Memorial Lecture).

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (Annual General Meeting) (at Victoria Hall Criterion Restaurant) at 8 30 —Discussion on How can the Chemical Engineering Group best assist in the Development of the Science and Practice of Chemical Engineering?

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Prof A E Boycott The Twist of Snail Shells

SATURDAY MAY 11

BIOCHEMICAL SOCIETY (in Department of Biochemistry University Museum Oxford) at 2 —K H Coward K M Key, and B G E Morgan Some Evidence of the Existence of a Further Factor Necessary for Growth of the Rat.—H Bainbridge E Boock, and J Trevan The Growth of Rats on Synthetic Diets —C R Harington and D A Scott Observations on Insulin —F H Carr K Culhane A T Fuller and Dr G W F Underhill A Reversible Inactivation of Insulin —W I Dilière R H Morton and Dr J C Drummond The Alleged Relation between Carotene and Vitamin A —H J Phelps The Mechanism of the Adsorption of Weak Electrolytes —H W Kinnersley and R. A. Peters Observations upon Carbohydrate Metabolism in Avitaminous Birds —R. A Peters The Third Factor of Williams and Waterman —B Woolf The Enzymes in *B. coli communis* which act on Fumaric Acid E Boyland The Lag between Phosphate Esterification and Carbon Dioxide Evolution in Alcoholic Fermentation —Demonstrations —Tachycardia in Rice fed Pigeons by C W Carter and R. A Peters —Blood Testing by Dr G L Peskett.

BRITISH PSYCHOLOGICAL SOCIETY (at Royal Anthropological Institute) at 3 —Miss E H. Walters Is there a Common Factor of Sensorial Retentivity and is it Influenced by Conation?—S. E W Taylor A Balance Showing the Relation of Blood Distribution to Mental Activity —J W Caughey Some Factors Involved in the Performance of Single Routine Tests

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (South Wales District) (at Council Chamber Swansea) at 2 15 —Discussion on Some Road and Other Schemes at Swansea R. Hutson Swansea Main Drainage Scheme and Flood Relief Schemes, J Hassall Llansamlet Sewage Pumping Scheme Swansea, M E. Habershon

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Sections) (at Harrogate).—Annual Meeting

MONDAY MAY 13

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30. —E B Worthington The Life of the Albert Nyanza and Lake Kioga

TUESDAY MAY 14

PHYSICAL SOCIETY (jointly with Society of Glass Technology) (in Research Laboratories of the General Electric Co. Ltd Wembley), at 4 —Prof W E S Turner and F Winks A Study of the Thermal Expansion of Glass up to the Softening Temperature —R. F Proctor and R W Douglas The Measurement of the Viscosity of Glass at High Temperatures by Means of the Rotating Cylinder Viscometer —F C Harris The Photo-Elastic Properties of Glass.

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Sections) at 5 —Annual General Meeting

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5 30 —G B. Maxwell and Dr R. V Wheeler Flame Characteristics of Pinking and Non Pinking Fuels Part II

INSTITUTION OF CIVIL ENGINEERS, at 6.—Annual General Meeting

ILLUMINATING ENGINEERING SOCIETY (at Home Office Industrial Museum Horseferry Road) at 6 45 —G H Wilson The International Commission on Illumination and the International Congress held in the United States in 1928.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —J A Speed Flashlight in Natural History Work.

QUEKETT MICROSCOPICAL CLUB, at 7 30 —Dr H A. Baylis Life histories of Parasitic Worms

ROYAL SOCIETY OF MEDICINE (Psychiatry Section) (Annual General Meeting), at 8 30 —Dr F L Golla Some Recent Work on the Pathology of Schizophrenia —Dr W M. F Robertson Gastro intestinal Focal Infection in Relation to Oral Sepsis, with Special Reference to Anaerobes occurring in 6 Cases of Mental Disorder

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30 —Dr A F Ashley Montagu The Tarsian Hypothesis in the Descent of Man

WEDNESDAY MAY 15

SOCIETY OF GLASS TECHNOLOGY (at University College), at 2 30.—Prof W E S. Turner The Glass Industry of North America in 1929

IRON AND STEEL INSTITUTE (in Mappin Hall Sheffield), at 2 30.—The Hon Sir Charles Parsons and H M Duncan A New Method for the Production of Sound Steel.—Third Report on Heterogeneity of Steel Ingots by a Committee of the Institute —G A. Hankins and Miss G W Ford The Mechanical and Metallurgical Properties of Spring Steels as Revealed by Laboratory Tests —L B Pfeil The Oxidation of Iron and Steel at High Temperatures —G R Bolsover Brittleness in Mild Steel —H Sutton The Influence of Pickling Operations on the Properties of Steel.

ROYAL METEOROLOGICAL SOCIETY at 5 —J E Clark I D Margary R Marshall and C J P Cave Report on the Phenological Observations in the British Isles December 1927 to November 1928 —D Brunt The Index of Refraction of Damp Air, and the Optical Determination of Lapse rate —Dr J R Ashworth The Influence of Smoke and Hot Gases from Factory Chimneys on Rainfall

ROYAL SOCIETY OF ARTS at 8 —R. Burrell The Reform of the British Patent System

EUGENICS SOCIETY (at Linnean Society), at 8

FOLK LORE SOCIETY (at University College), at 8 —Dr M Taylor Norfolk Folk Medicine

ROYAL MICROSCOPICAL SOCIETY at 8 —E Heron Allen and A Earland Some New Foraminifera from the South Atlantic No I —R. Paulson The Form of the Chromatophore of the Bright Green Gonidium common to many Lichens —D Bryce On Three Cases of Encystment among Rotifers

ROYAL SOCIETY OF MEDICINE (Tropical Diseases Section) (Annual General Meeting) at 8 15 —Prof Besredka Vaccine Therapy

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) —Annual Business Meeting

THURSDAY MAY 16

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5 —Prof C G Darwin The Refraction and Scattering of Light (Lecture).

INSTITUTE OF PATHOLOGY AND RESEARCH (St Mary's Hospital) at 5 —Prof F T G Hobday The Value of Research into Animal Diseases as an Aid to the Study of the Diseases of Man

INSTITUTION OF MINING AND METALLURGY (at Geological Society of London), at 5 30

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College Dublin) at 7 45 —Annual General Meeting

CHEMICAL SOCIETY at 8.—Prof T M Lowry The Validity of Drude s Equation —A I Vogel The Dissociation Constants of Organic Acids Part I The Primary Dissociation Constants of some Alkyl Malonic Acids —Prof T M Lowry and W V Lloyd The Properties of Nicotine and its Derivatives Part I Molecular Extinction coefficients Part II Optical Rotatory Power and Rotatory Dispersion —A I Vogel The Dissociation Constants of Organic Acids. Part II The Primary Dissociation Constants of some Cyclo 1 1-dicarboxylic Acids

The Research Associations

THE Report of the Department of Scientific and Industrial Research for the year 1927–28 (Cmd 3258) devotes considerable attention to the position, in the national economy, of the research associations set up in Great Britain under the ægis of the Department Since 1918, when the first three associations were established, some twenty-six research associations in all have been formed Two of them, relating to the glass and cement industries respectively, have been wound up, and of the twenty four associations still in being, one, the British Iron Manufacturers' Research Association, has not received grant aid from the Department, and its operations were suspended at the close of the first quinquennium and have not, up to the present, been resumed The British Colliery Owners' Research Association, founded in December 1924, has not received grant aid from the Department, and three other associations (Motor and Allied Manufacturers, Motor Cycle and Cycle Car, and Scottish Shale Oil) ceased to receive Government grants at the end of their first quinquennium

It will be remembered that the original scheme of the Department of Scientific and Industrial Research provided grant aid from the million fund, set aside by the Government to promote scientific and industrial research, on the basis of annual grants equivalent to the annual subscriptions of members of the associations The scheme further provided that the grant in aid should be limited in each case to the first five years of the association's life It was assumed or believed that a period of five years would be sufficient to demonstrate effectively that co operative research was of value to industry, and that, as a result of that demonstration, the several industries that had embarked on the experiment would be willing to shoulder thereafter the whole financial burden of maintaining their respective research associations In fact, as the report of the Advisory Council to the Department states candidly, "five years proved too short a time for most of the Associations to establish their reputation by the results of their work"

There need be no surprise at this conclusion, for the first two years of an association's life are necessarily spent mostly in setting up the organisation, gathering together the appropriate scientific staff, securing the buildings and equipment, and planning a comprehensive research programme It would be more than remarkable if, in the remaining three years, the results of any association's

work should be sufficiently striking to convince manufacturers (presumably having little or no previous experience of research applied systematically to their respective industries as a whole) that co operative research was of such immediate and valuable service to industry that it would be a ' business proposition ' for them to bear alone its necessarily high expense St Paul may have been amenable to quick conversion, but the average British manufacturer is, shall we say, less impetuous Indeed, even now, after some ten years experience of the work of the research associations the report of the Advisory Council to the Department says ' It cannot be denied that most of the Associations find it difficult to get the financial support they deserve A subscription to a Research Association is still regarded in many cases as a charitable gift, to be paid with public spirit and private reluctance and to be withheld when funds are scarce "

At the end of the first quinquennium, therefore, the Department, looking the facts in the face, agreed to a continuance of State aid, though on a smaller scale, for a further period of five years The scale of grants was not only smaller but also, in general, it was a descending scale, calculated so that at the end of this second quinquennium the grants would sink to zero The stipulated grant earning subscriptions were correspondingly based upon an ascending scale so that the total income of the association should remain about the same and the association be self supporting at the end of this second period of five years But again, in fact, it was found impossible by many, probably by most, of the associations to fulfil the conditions of this carefully planned, if still heroic, scheme and the Department, again facing the facts realistically and sympathetically, consented to modify in a more generous direction the conditions on which a number of the associations might continue to receive grants during this second quinquennium To the associations, however, the problem remained of what was to happen to them on the termination of this second quinquennium It was doubtful, to say the least, whether the majority of them could become financially self supporting, on an adequate scale, immediately this second grant period ceased

Accordingly, nineteen of the research associations during the past year submitted by deputation a reasoned memorial to the Lord President of the Council, the Earl of Balfour, praying for a continuance of financial assistance by the Department on the pound for pound scale The Lord President was unable, on behalf of the Government, to accept the proposals of the memorialists, but he announced a new policy which goes some way to meeting the difficulties with which the associations are faced When the existing contracts for the second quinquennium come to an end, each association is to be considered on its merits and a subscription income fixed which it will be necessary for the association to obtain from other sources before it is eligible for any grant from the Department Funds obtained from approved sources in excess of this minimum subscription income will be augmented by a grant equal in amount from the Department up to a limit depending on the circumstances of the association

That, stated briefly, is the substance of the Department's policy, in the near future, with respect to grants in aid of the research associations, and it is further evidence of the willingness of the Department, to which attention has already been directed to modify and adapt its policy to new facts and changed circumstances The inflexible attitude of ' What we have said we have said " has been wisely left to political heroes The Advisory Council has been mindful throughout that it has a fiduciary duty to ensure, so far as it may reasonably do so, that scientific and industrial research, in close association with industrial effort, plays its essential part in national recovery

The next few years will show whether the new policy is sufficient to enable the research associations to weather the difficulties of the long period that must still ensue before the indifference and inertia, in this matter of research, of the general body of manufacturers (more particularly perhaps of those engaged in industries that have been hitherto largely run on rule of thumb) can be overcome Obviously, very much will depend, in each case, on the minimum subscription income fixed to qualify for grant The Advisory Council states ' We do not, in any case, intend to fix it lower than an amount which, in our opinion, would be sufficient to maintain the Association in being as a useful nucleus of research The State's contribution would then be used to assist in transforming the nucleus into a well-nourished adult and productive organisation " The associations must take hope from the biological fact that nuclei are generally small, and that it should be well within their powers to provide the funds necessary to maintain an organisation that can satisfy the Department's idea of a useful nucleus The Department has of course a duty to the taxpayers not to put the limit too low it has a corresponding duty to the

cause of industrial research, which its own inclination will prompt it to fulfil, not to put the limit so high as to make it prohibitive

Before or at this point the question naturally arises whether the work already done by the research associations has justified their foundation and the money expended by them On this point the Advisory Council—and it is in the best position to know—says categorically "The main purpose has, in our opinion, already been achieved Co operative research has proved its value, it has come to stay, and we agree with the views expressed in the memorial on the importance of consolidating now the financial position of the Associations" The final report of the Balfour Committee on Industry and Trade, issued on Mar 11, emphasises the importance of progress in scientific research and a clearer line of demarcation between the function of the State and that of industrial undertakings either singly or in co operation In particular, the Committee urges that there should be no relaxation or curtailment of the efforts of the Department of Scientific and Industrial Research, and no withdrawal of financial support on the part of the Government

In connexion with this last recommendation it is worth notice that the late Prof Alfred Marshall, the distinguished economist, in his "Industry and Trade", first published in 1919, specifically recommended public grants to research associations on other and perhaps unusual grounds After pointing out that the research associations are "wholly constructive", he says "But the experience of the ages shows that Associations set up for constructive purposes are in danger of being turned to destructive ends and therefore it may perhaps be to the public interest that some limited contribution should be made from public funds to the support of such Associations, partly in order to facilitate the intervention of public authority in case an association should develop anti social tendencies" The reader may find it interesting to make speculations on the character of these "anti social tendencies" presumed to be latent in the research associations

There is a great area of British industry occupied by numerous medium sized and small firms, directed by strongly individualistic owners, too small to enable industrial research to be prosecuted, on any adequate scale, on an individual basis Despite the modern tendency towards larger aggregations of capital by the fusion of smaller firms, it is likely that a very great field of British industry will continue for long to be represented by these medium sized or small manufacturing units For them the only practicable scheme of industrial research, on a sufficient scale, is co operative research, *i e* the organised co operation of groups of firms to provide the funds and the equipment, both personal and material, for the needed research In this field it is most important to find for Government action the golden mean between policies of *laissez faire* and spoon feeding

Geometry and Relativity

Philosophie der Raum Zeit Lehre Von Prof Dr Hans Reichenbach Pp vi + 380 (Berlin und Leipzig Walter de Gruyter und Co, 1928) 18 gold marks

THE appearance of a work on the philosophy of a branch of mathematical physics by a trained philosopher, who at the same time has a thorough knowledge of mathematical and physical methods and principles, is an event as rare as it is welcome This book by the Berlin philosopher Reichenbach, well known to mathematical physicists by his writings on relativity, is unique and should be in the library of everyone interested in geometry and relativity in their philosophical as well as mathematical and physical aspects, fully deserving a place beside the standard treatises of Bertrand Russell and Whitehead It is divided into three sections, the first on space (120 pages), the second on time (45 pages), and the third on space time (155 pages), whilst there is an appendix (42 pages) on Weyl's extension of Riemannian geometry and the geometrical interpretation of electricity, which forms the basis of a recent paper by the same author on Einstein's new field theory of gravitation and electricity In the brief space available here it is impossible to do full justice to the author's argument, but the following summary may be useful as an indication of the character and scope of this very important work

In the first section the argument proceeds as follows there is no pure intuition *a priori*, all intuition is determined by past experience Non-Euclidean geometry is just as intuitive as Euclidean, but one must not expect to be able to imagine non Euclidean geometry by means of Euclidean elements Experience decides which geometry is valid in actual space, but the decision presupposes an arbitrary correspondence definition (*Zuordnungsdefinition*), which defines the unit of length in a given place and permits of a definition of congruence of lengths in different places by means

of transportable rigid measuring rods Any geometry may be made to agree with the behaviour of actual measuring rods by postulating suitable universal forces, so that the deviations from the selected geometry are made to depend on universal deformations of the measuring rods

In the second section the author develops rather novel views Whilst recognising the fruitfulness of the mathematical conception of space and time as a fourfold, he emphasises the point that thereby time does not lose its special character and become a fourth space dimension The comparison of times, like that of lengths, depends on an arbitrary correspondence definition, which defines simultaneity of events occurring in different places Order in time is determined by the law of causality, for the effect is later than the cause, and we can distinguish the cause from the effect, because small variations in the former produce small variations in the latter, whilst the converse is not true The comparison of time-orders in different places depends upon the propagation of signals, and experience shows that the greatest signal velocity is that of light and is finite, so that to every instant of time at a given place there corresponds a finite interval of time at a second place, in which no instant can be connected with the first by a to-and-fro signal Hence the given instant at the first place may be defined as simultaneous with any one instant of the corresponding time interval at the second place

In the third section the author first discusses space-time manifolds free from gravitation, pointing out that comparison of lengths in relative motion to one another requires a new correspondence definition, which defines the length of a moving segment as the distance between simultaneous positions of its two endpoints Experience shows that material structures, like measuring rods and clocks, conform to the relativistic and not to the classical light geometry, so that they measure 'intervals', not spaces and times Passing on to manifolds with gravitation, the author gives the history of the idea of the relativity of motion from Leibniz to Einstein, pointing out that the very idea of motion is meaningless without a correspondence definition of rest the relative motion of the earth and fixed stars is itself not an absolute fact, but only relative to systems of co-ordinates realisable by means of rigid bodies He then analyses in turn Einstein's principle of equivalence and its hypothetical character, his concept of gravitation and its covariance, and his treatment of the rotation problem and idea that every system of co-ordinates requires its own gravitational field and points out the failure of some of the critics to realise that the relation of cause and effect is invariant, not covariant This analysis of the space time properties of gravitational fields leads the author to the important conclusion that the combined space time order is the order scheme of causal sequences and expresses the causal structure of the world

The final discussion of the general properties of space and time begins with the characterisation of time as that dimension of the space time manifold which determines the direction of the world lines of things distinguished by the preservation of their identity, which direction is also that of the causal sequences Then follows a discussion of the number of dimensions of the space-time manifold, ending with the conclusion that the assertion that physical space has three dimensions is on a par with the assertion that matter exists in three states of aggregation it describes a fundamental fact of the objective world, for which no explanation has yet been found Finally, the author declares that the reality of space and time follows inevitably from his analysis of the problem

The appendix begins with the reminder that Riemannian space presupposes congruence definitions realisable by means of rigid measuring rods and clocks, which can be displaced along different paths without violating their properties of congruence If, however, two measuring rods, congruent at the same place and time, cease to be congruent after displacement to another place by different paths, some displacement law is needed to determine the changes of length and direction due to displacement This can be supplied by the postulate that a certain vector at one point after displacement can be identified with a second given vector at another point—this correspondence defines a displacement process and determines a displacement space (*Verschiebungsraum*), just as the usual congruence definition determines the 'metric space'

In order that the two definitions may lead to mutually consistent results, certain conditions must be imposed we may demand that the displacement law shall have a certain symmetry and thus derive Riemannian space from the most general metric space, or that the displacement of lengths shall be integrable, that is, independent of the path, and thus derive a general Einstein's space, or we may impose both conditions and thus derive Euclidean space The displacement process can be realised by means of rigid measuring rods and clocks, and then it determines a length displacement and a gravitational field, or it can

be realised by means of an electrically charged mass particle, and then it determines a directional displacement and an electromagnetic field But whilst the geometrical interpretation of gravitation given by the length displacement has led to an increase of physical knowledge in the shape of Einstein's theory of gravitation, the geometrical interpretation of electricity given by the directional displacement has not led as yet to any advance in the physical theory of electricity

Geophysics

Handbuch der Experimentalphysik Herausgegeben von W Wien und F Harms Unter Mitarbeit von H Lenz Band 25 *Geophysik* Teil 1 Unter der Redaktion von G Angenheister Pp xiv + 699 (Leipzig Akademische Verlagsgesellschaft m b H , 1928) n p

GEOPHYSICS, like astronomy, is advanced jointly by observation and theoretical discussion, and direct experimental illustration of its phenomena is rarely possible The inclusion of this book in a 'handbook' of experimental physics is therefore slightly anomalous, but the volume is none the less welcome Geophysics is of immense scope, because a wide variety of physical properties have to be examined as regards their distribution over the globe, and in many cases also as regards their variations over long periods of years Observation is the primary necessity, but devotion to this duty creates difficulty owing to the volume of the data accumulated The next task, scarcely less important, is to distil the essential facts from this vast material—a laborious process, involving the systematic comparison of data from many stations and, in some cases, heavy computations upon long series of observations to investigate periodic and other changes The third and, in general, most difficult task is to bring the phenomena thus elucidated into relation with general physics , many hypotheses may have to be examined, sometimes requiring extensive mathematical developments and the extrapolation of laboratory results to extreme conditions of temperature or pressure Frequently, the hypotheses prove totally at fault as regards order of magnitude, while in other cases judgment must be held in suspense because some of the factors involved are not yet capable of measurement

Owing to these difficulties, geophysics makes slow progress, but, as in general physics, the discovery of new fields of observation, and the advance of instrumental technique, are throwing light from new directions upon obscure problems, though also disclosing new mysteries for solution A worker in any special branch of geophysics must, therefore, keep acquainted with the progress made in other branches, as well as with general physics Unfortunately, there is a dearth of books summarising geophysical knowledge, and the present volume is a useful supplement to those that exist

This volume is only the first part of the geophysical section of the 'handbook' (as the series of more than twenty five bulky tomes is curiously called) , since no indication is given of the contents of the further parts, it is impossible to judge the balance of the work, or the extent to which the ground will be covered This first part is devoted mainly to the atmosphere, with the partial exception of the last section, on terrestrial magnetism, which may be intended to achieve the transition from dizzy heights to solid earth" The first quarter (165 pages) of the book, by A Defant, deals with the general dynamics and statics of the atmosphere, apart from its tidal and thermal oscillations—an interesting but little known chapter of geophysics, of which an excellent account (48 pages) is given by J Bartels W Milch summarises the optics of the atmosphere (44 pages), and H Benndorf the electrical phenomena (128 pages) apart from the aurora, which is described by L Vegard (94 pages), and the penetrating radiation (K Büttner, 48 pages) Terrestrial magnetism (158 pages) is dealt with by G Angenheister and J Bartels The book concludes with good indexes of subjects and authors

Owing to the small scale of the book in relation to the wide scope of the subject, the treatment is necessarily brief and general Its value must be judged by the extent to which it indicates the main outlines, results and problems of each section, and by the guidance to the literature which is afforded for those readers who wish to follow up any question in detail In the latter respect the book is somewhat unequal, as is natural in a collective work , in some sections the references are carried up to 1927 or even 1928, the year of publication, while in others there are few so late as 1926, though much of importance has since appeared , a rather long interval seems to have elapsed between the preparation of some of the sections and the publication of the book

The general treatment is good, notably so in some sections, and the book is well illustrated Where controversial or uncertain points are touched on, the position is usually explained with proper reserve Vegard's article on auroræ is the least satisfactory in this respect, since it unduly stresses

his own theory of the auroral spectrum and the upper atmosphere In an addendum inserted during proof correction, McLennan's identification of the green auroral line as due to oxygen is admitted, but the remainder of Vegard's theory, postulating an atmosphere above 90 km, composed of frozen nitrogen crystals upheld electrostatically, is maintained The aurora is still very mysterious but there are probably few physicists who would accept this solution

The conditions in the upper atmosphere are touched on in several sections of the book Defant and Benndorf seem to favour the view that hydrogen is the main constituent above 100 km, though to the reviewer the balance of evidence seems opposed to this conclusion On p 3, Wegener's hypothetical substance geocoronium is mentioned surely this speculation might by now have been allowed to lapse into oblivion, being, as it is, totally at variance with modern atomic physics and the evidence of the mass spectrograph The work of Lindemann and Dobson on the upper air temperature is only briefly mentioned, though their conclusions now seem fairly established by confirmatory evidence drawn from the abnormal propagation of sound to great distances, and from the absorption of solar radiation by ozone But while in a few respects some parts of the book fall short of the thoroughness commonly attributed to German works of reference, it would be wrong to magnify minor faults in a work which as a whole has solid merits and can be recommended as a good general account of the subjects falling within its scope

Spencer's "Sociology"

Descriptive Sociology or Groups of Sociological Facts, Classified and Arranged By Herbert Spencer *Hellenistic Greeks* Compiled and Abstracted upon the Plan organised by Herbert Spencer, by the late Sir J P Mahaffy and Prof W A Goligher (Completed by Prof W A Goligher) Issued by Mr Spencer's Trustees Pp vi+94 (London Williams and Norgate, Ltd, 1928) 63s net

"A LARGE book," said a Hellenistic Greek, "is a large evil" What are we to say of one the dimensions of which are nineteen and a half inches by twelve and a half? It will go into no ordinary shelf, it is awkward at best to handle, the tops of the three parallel columns of small print which fill each page are most inconveniently remote to the myopic The physical difficulties of the format are doubtless imposed by Spencer's belief, which I do not personally share, in the utility of an elaborate chart of tabulated conclusions The book in shape and substance is drawn up according to Spencer's plan and, regarded as a monument *in piam memoriam*, it is well and truly constructed

It would of course be easy, as in all compilations of this scale, to make reviewer's points A few accents have gone wrong, there are some misprints, the bibliography does not, as the preface suggests, mention all the works from which quotation is made In the illustrative passages taken from ancient authors it might be held that for the last period too exclusive reliance has been placed upon Lucian and Plutarch Some of the moderns who are cited might be thought a little old fashioned Did not Rostovtzeff's book appear in time for inclusion among writers on the Imperial period, and why should references be given to the second edition of Dittenberger's "Sylloge", the numbering of which has been superseded by the third? Again, one might catch some little point for example, the belief that Prof Goligher shares with Rohde that oriental influence had something to do with the total veiling of women at Tarsus The gloss becomes unnecessary when it is realised that what we may call severity in veiling varied in different Greek States and that the Theban women, for example, in European Greece wore veils which permitted nothing but the eyes to be seen

These are, however, small and some of them disputable matters No one who has a professional interest in ancient history will refuse his meed of admiration for the wide knowledge, industry, and patience which Prof Goligher has expended on his task At that we might leave it, were we not bound to ask whether the result justifies the very considerable labour which has gone to its achievement Regarded as a memorial to Herbert Spencer the book might earn a favourable verdict, but regarded as a useful contribution to ancient history the answer must be less confident Clearly, it is not intended for cursive reading and will not fall easily into the category of a scholarly presentation of the subject to the general public Of works for the specialist reader there are three useful kinds either we expect them to contain new matter of fact or theory which is the result of original research, or, secondly, we look for the presentation of known facts in a new light, or, thirdly, we are grateful for a handy and complete compilation of facts already known It is in the last category that the book must claim to stand, and here it must be confessed that it is vastly inferior in content as well as in convenience of format to the great dictionaries with which the

classical student of to day is so well supplied From them information more detailed and more complete can be obtained with greater ease and, it may be added, a more structural knowledge of the problems connected with the interpretation of the evidence W R H

Preston's "Heat"

The Theory of Heat By Prof Thomas Preston Fourth edition, edited by J Rogerson Cotter Pp xix + 836 (London Macmillan and Co, Ltd, 1929) 25s net

TO publish a fourth edition of a scientific work thirty five years after the appearance of the first edition is a high tribute to the author, particularly when, as in this instance, no very fundamental change has been made in the scheme of the book It is the more notable in experimental science, since Preston could write in 1894 that "It is but a short time since the pursuit of experimental research was regarded merely as a matter of individual curiosity"

Whilst it is not easy to single out any one specific reason for the active survival of "The Theory of Heat", there seem to be in it several outstanding features which have combined to contribute to its continued usefulness The most essential of these is undoubtedly Preston's singularly clear and accurate style One wishes, in fact, that the first chapter, with its admirable general introduction to the subject, the seventh, on conduction, and the following one on thermodynamics—which is perhaps the best elementary account that has been written, and of which Preston is said to have been justifiably proud—could be obtained separately for examination purposes by students who have no use for the whole volume Another reason is in the time at which Preston wrote The epoch making work of the end of the century on the electron had still to be done, and there can sometimes be sensed in contemporary writings the feeling that the apparent limitations of the scientific horizon were real

Preston, whether or not he subscribed to this view, can scarcely fail to have been aware of it—he took the precaution of pointing out that "any theory, however plausible, may ultimately become untenable"—and he could thus write with greater confidence than if he had started a few years later, when he had become interested in the new physics, and was himself engaged in research on the Zeeman effect. It must also be remembered that he was dealing not only with a subject that appeared to be sound theoretically, but also that even then he had to describe experiments that aimed at, and often attained, considerable precision Again, Preston states that he was attempting "to treat the science of heat in a comprehensive manner", and not "to meet the requirements of some particular class of persons preparing for examinations or engaged in practical pursuits", an ideal which is also realised in Tyndall's earlier "Heat a Mode of Motion" and Kayser's original pygmy "Lehrbuch der Spektralanalyse" of 1883

Mr Cotter's revision of the third edition of Preston's book is chiefly on the experimental side The square brackets which had previously marked off paragraphs which were not parts of Preston's own contribution have been removed Several condensations and omissions have been made, notably in the description of experiments and in discussions of disputed points which have now lost their interest In their places are accounts of some more modern investigations, which have been chosen with discrimination—for example, Stock's realisation of Kelvin's proposed vapour pressure thermometers, and Hercus and Laby's determination of Joule's equivalent—and there are several new references to quantum theory at the appropriate places in the text The book is naturally still far from complete, but it was never intended to be a dictionary of the subject Mr Cotter's task has rather been to retain the spirit and scope of the edition of 1894, but at the same time to make some necessary alterations in parts that were obviously out of date, and in this he has been entirely successful K G E

Our Bookshelf

Anleitung zur chemischen Gesteinsanalyse Von Prof Dr J Jakob (*Sammlung naturwissenschaftlicher Praktika*, Band 15) Pp vii + 81 (Berlin Gebrüder Borntraeger, 1928) 7 gold marks

THE lack of a short but comprehensive work dealing with rock analyses has inspired Prof Jakob to produce this book, which is intended primarily for the use of students in the laboratory It may be placed in the hands of a beginner possessing a sound knowledge of general chemistry, and will enable him to carry out a complete analysis

The author makes a distinction between rock and mineral analyses, each calling for a different method of treatment In a mineral analysis the object is to attain the most accurate result possible, independent of time, with a rock analysis, on the other hand, it is to produce in the shortest possible time a sufficiently accurate result to represent the specimen Any two independent analyses carried out on the same powder show points of divergence, and this is even greater in the case of two portions of

the same rock, hence great accuracy of method is not practical and does not justify the time necessary At the same time, however, Prof Jakob considers that analyses should be more accurate than many quoted in the literature

Directions are given for the preparation of the sample, fineness of grinding, etc , depending on the presence or absence of certain minerals and also on the determination to be carried out The main part of the book deals with the determination of the various oxides, a useful feature of this section being the incorporation of all explanations of processes in the form of footnotes, leaving the text free from interruptions All analyses must be carried out only after microscopic examination, which serves as a qualitative examination this is most important, as the method used for the estimation of the sesquioxides TiO_2 and MnO depends on the quantity of the oxide present The concluding section deals with rock analyses in general in which the author discusses the characters of good and bad analyses finally he includes a description of the calculation of an analysis into Niggli values

Vestiges of Pre Metric Weights and Measures persisting in Metric System Europe, 1926–1927 By Prof Arthur E Kennelly Pp xiii + 189 (New York The Macmillan Co , 1928) 2 50 dollars

As the metric system of weights and measures has now been exclusively adopted by nearly every European country, it is of some interest in connexion with proposals for its adoption by other countries to ascertain if possible to what extent its imposition upon the various peoples has hitherto proved effective The most obvious means of obtaining information on this matter would appear to be the study of the periodical reports and other publications of the respective Weights and Measures Departments Disdaining, no doubt, such arm chair methods, Prof Kennelly set himself the task of collecting evidence as to the persistence of pre metric vestiges by personal observation and inquiry in all the principal countries concerned This he accomplished under the auspices of the Bureau of International Research, during a sabbatical leave of absence granted him by Harvard University from July 1926 until September 1927

That the arduous but well ordered programme of the author was carried out with scientific zeal and discrimination is abundantly apparent , that official statements are often susceptible to enlightening amplification from other sources is demonstrated by a comparison of some of the letters received from officials and laymen, respectively, in the same locality But the net result arrived at, namely, that where pre metric terms persist they have practically always been ' metricised ' or ' submetricised ' in actual use, does not differ remarkably from the probable conclusions of any person whose pursuits entail frequent contact with administrative publications on weights and measures Nevertheless, this is a valuable work of reference with regard to the old units, their names, equivalents, and distribution W H M

Autolycus or the Future for Miscreant Youth By Dr R G Gordon (To day and To morrow Series) Pp 94 (London Kegan Paul and Co , Ltd New York E P Dutton and Co , 1928) 2*s* 6*d* net

ANYONE who has acquainted himself with Dr R G Gordon's larger works on " Personality " and " The Neurotic Personality ' will acknowledge the *a priori* likelihood of his writing a useful and authoritative pamphlet on juvenile delinquency, including the way in which society itself does much to produce its quota of pickers up of unconsidered trifles He quotes Samuel Butler to the effect that in Erewhon " a man who catches a disorder is punished whereas a thief or a rick burner is sent to a hospital , and the burden of his argument is that Butler s paradox is not so violent as it seems at first sight We punish the child who marks the wall paper instead of giving him materials for the proper exercise of his artistic prowess we punish the boy who plays football in the street, instead of providing him with a playing field and we assume that a girl who has been rescued from a life of infamy is best dealt with by being pitch forked into domestic service or into a public laundry Dr Gordon gives a simple and eminently readable account of the social educational psychological and medical factors involved in the treatment of miscreant youth and he makes a case for the calmly scientific instead of the emotional and half revengeful methods which at present hold the field

The Frog an Introduction to Anatomy Histology, and Embryology By the late Prof A Milnes Marshall Edited by H G Newth (Macmillan s Manuals for Students) Twelfth edition Pp x + 182 (London Macmillan and Co Ltd , 1928) 6*s*

MR NEWTH has left this work which had not been revised since 1912, in its well known form, but has made a number of useful alterations He has introduced into the section on technique notes on the use of methylene blue, eosin, and formalin, and has improved the instructions on section cutting The suggestion that the female frog should be dissected in saline solution to prevent the great swelling of the contents of the oviducts, the instructions for making and staining a blood smear, and for the preparation of the frog's bladder to show unstriped muscle, are helpful, and the dorsal dissection of the abdominal region of the frog, for which brief directions are given affords the student a view of the relations of certain blood vessels and organs from another aspect, and is useful as a revision exercise The description of the section of the retina, of the fertilisation and early development of the frog's egg, and of mitosis and meiosis, have been amended, but here and there the editor has carried over from the old edition words not consistent with his present description , for example, the use of the term ' egg ' on p 116 The terms epiblast, etc , might now be replaced by ectoderm, etc On p 55 the brief note on the second row of tarsal bones has been omitted

Palæolithic Man in Ireland

No one ever questioned the possibility that traces of palæolithic man might one day be found in Ireland, in spite of the negative results of excavations, chiefly in caves, carried out over many years by the Royal Irish Academy and the Royal Dublin Society From time to time individuals have announced their discovery of palæolithic implements, but in every case such reports were open to the gravest scientific objection It is therefore with very special pleasure that we welcome the news contained in the accompanying statement, that the discovery has at last been made

The work which has thus been crowned with success was carried out last August, by a party of the Bristol Spelæological Society, under the leadership of Mr E K Tratman It was financed by the Royal Irish Academy, and some members of that body made the local arrangements and collaborated in the excavation , but the credit of the discovery is due to Mr Tratman and his colleagues

A short time ago we found ourselves constrained to adopt a position adverse to a discovery of alleged palæolithic implements on the west coast of Ireland We have never seen any reason to change our views on this matter everything that has been written about it, and every visit which we have paid to the site, have only confirmed us in our opinion Every possible explanation has been sought for our attitude, except the simple and obvious one that we did not, and do not, consider the 'discovery' in question to be more worthy of scientific acceptance than any of its not infrequent predecessors of the same type We have been accused of upholding preconceived prejudices in the face of evidence We have been accused of the yet more unworthy motives of personal or national jealousy We are therefore the more happy in being able to express our complete acceptance of the discovery here announced, and our full appreciation of its importance

EXCAVATIONS AT KILGREANY CAVE, NEAR DUNGARVAN, CO WATERFORD, 1928

IN the summer of 1928 excavations were carried out at this cave under the auspices of a joint committee, consisting of members of the Royal Irish Academy and the Spelæological Society of the University of Bristol The work was carried out personally by the members of the committee, assisted by students from Trinity College, Dublin, and the University of Bristol

The excavations gave the following stratification, outside the present cave mouth

1 Quarry debris from the roof of the former outer chamber of the cave, 0 2 ft

2 Hearth number 1, of late Bronze to early Iron Age date, 2 4 ft

3 A layer of brown earth and stones, with but few finds

4 Hearth number 2 Part of a polished stone axe came from this, suggesting a very late Neolithic to early Bronze Age date A number of human skeletons, very fragmentary, came from this level, 4 ft 4 ft 6 in

5 A stalagmite floor, divided into an upper tufaceous portion and a lower crystalline part These were separated by a third hearth The crystalline stalagmite was barren of remains, 4 ft 6 in 9 ft

6 A layer of loosely piled stones of unknown depth, but reaching to a depth of 12 ft from the original surface No remains from this layer

The surface of layer 5 was intact, all over the area in which it was exposed Before the task of excavating it was begun, special care was taken to ensure that all the upper deposits had been removed

Leaning against a projecting piece of the wall of the cave, and originally held in position there by a pile of stones (which had become completely embedded in the stalagmite as this material accumulated), was a human skeleton in a semi crouched position, with the left side against the cave wall As the limbs of the skeleton were traced down, through the stalagmite, to the level of the third hearth, and as there was absolutely no evidence of there ever having been any disturbance of the stalagmite by a burial inserted from above, it is obvious that the skeleton represents a deliberate burial from the level of the third hearth , a fact of first class importance from the archæological and anthropological points of view and one also that has important bearing on some of the geological problems of the late Pleistocene period

The fauna yielded by the tufaceous part of the stalagmite was as follows wild boar, Irish giant deer (or 'Irish elk'), reindeer, brown bear, wolf, fox, cat, stoat, hare, field mouse, Arctic lemming, birds, and land mollusca This is a very typical Late Pleistocene fauna

The presence of the skeleton, and the third hearth actually at the base of the deposit yielding this fauna, is conclusive proof of the presence of man in the south of Ireland in Late Pleistocene times It is unfortunate that as yet no implements have been recovered, so that we cannot yet place this Late Pleistocene man in his correct division of the Upper Palæolithic cultures

A full illustrated account of this discovery will be published in the next issue of the *Proceedings* of the Bristol Spelæological Society, now in course of preparation E K TRATMAN

Selection Rules in the Raman Effect

RECENT experimental work by McLennan (NATURE, Feb 2, 1929) on liquids and by myself (*Proc Nat Acad Sci* March 1929) on gases has shown definitely that transitions between vibrational levels of a non polar molecule such as nitrogen, oxygen, or hydrogen take place in the Raman effect I have pointed out that this, far from being inconsistent with the well known selection rules, is exactly what we should expect to happen from the quantum mechanical theory of dispersion

The selection rule which works in the Raman effect can be stated as follows in order that a shift corresponding to the transition $i \rightarrow k$ may be observed, it is necessary that *both* states i and k combine at least with a third state l, the Raman scattering becoming particularly intense when the energy $h\nu$ of the impinging quantum is near to $E_l - E_i$ If $E_l - E_i = h\nu$, we have fluorescence instead of a Raman effect

The latest results I have obtained on gases, with an improved apparatus, seem to fit very well with this theoretical scheme I will give here a brief account of them

I have extended the investigation in the ultra violet, using the line λ2536 of mercury, since the intensity of

the scattered radiation increases very rapidly with the frequency of the exciting light. This proved very successful, the intensity of the Raman lines scattered in gases being sufficient to record them in a large quartz Hilger spectrograph with a 60 hours' exposure. In this way a considerable improvement in resolution has been achieved as compared with the apparatus previously used for the visible region. An iron arc spectrum has been used as a standard, and under favourable conditions Raman lines have been measured with an accuracy of a frequency unit or better. The dispersion in the $\lambda 2536$ region was 131 frequency units per millimetre.

The most interesting feature of Raman spectra excited under these conditions in oxygen and nitrogen is the appearance on both sides of the line $\lambda 2536$ of a number of equally spaced lines, evidently due to rotational transitions. Four or five of them can be measured fairly well.

Now let us see what we should expect the rotational Raman spectrum of such a molecule to be like. Consider first the case of oxygen. Here the electronic bands to which the existence of rotational (and vibrational) Raman transitions is due (in the meaning that the upper levels of these electronic transitions play the rôle of the l state of the above stated selection rule) are essentially the bands of the Schumann Runge system, a ${}^3S \longrightarrow {}^3S$ transition. These consist only of a P and an R form branch, the lower (normal) electronic state possessing only odd, and the upper only even rotational states. Now consider a molecule in the lowest electronic state, and in the mth rotational state ($m = 1, 3, 5 \ldots$). This state combines only with the $m-1$ and $m+1$ rotational states of the upper electronic level. The first of these combines with the m and the $m-2$ rotational states of the normal electronic level, the second with the m and $m+2$. So, on the whole, the possible Raman transitions from the m rotational states to other rotational states are $m \longrightarrow m-2$, $m \longrightarrow m$, $m \longrightarrow m+2$. The second of them involves no change in energy—that is, gives scattered light of unmodified frequency. Of the other two, we need only consider what happens in the transitions involving a degradation in frequency ($m \longrightarrow m+2$), the others, of course, giving only anti Stokes's lines symmetrical with respect to the exciting line.

At room temperature, the Boltzmann distribution gives an appreciable amount of molecules for values of m up to ten or fifteen.

Now, we have, for the rotational energy

$$E_m = \frac{h^2}{8\pi^2 I_0}(m+1)m,$$

so that the Raman shift (in wave numbers) is

$$\Delta\nu = (E_{m+2} - E_m)/hc = (4m+6)h/8\pi^2 c I_0.$$

We should have a pattern of equally spaced lines, the spacing being 8 times the constant $h/8\pi^2 c I_0$. Only the first line should be spaced 10 times this constant from the exciting line.

The spacing in oxygen is too small to verify this last point, as the first three or four lines on each side overlap with the over exposed image of the $\lambda 2536$ line. But it was possible to measure fairly accurately the spacing of the lines. This gave the result $\Delta\nu = 12.0 \pm 0.5$ cm.$^{-1}$ Ossenbruggen finds the value $\Delta\nu = 11.5$ cm.$^{-1}$, thus agreeing within the limits of experimental error (W. Ossenbrüggen, *Zeit. f. Phys.*, **49**, 167, 1928; R. S. Mulliken, *Phys. Rev.*, **32**, 186, 1928). The triplet separation of the normal state in oxygen (R. S. Mulliken, *Phys. Rev.*, **32**, 880, 1928) is much smaller (2 cm.$^{-1}$), and we do not need to take it into account.

With nitrogen I have obtained a much better plate, on which the rotational components could be measured within a few tenths of a frequency unit. I give in the following table the measured frequencies, the meaning of the calculated values being explained later.

Obs.	Transition	Calc.	Difference
39504.4	$12 \longrightarrow 10$	39504.6	−0.2
39489.1	$10 \longrightarrow 8$	39488.6	+0.5
39472.5	$8 \longrightarrow 6$	39472.6	−0.1
39456.6	$6 \longrightarrow 4$	39456.6	0
39412.6	Exciting line	39412.6	
39352.6	$6 \longrightarrow 8$	39352.6	0
39336.6	$8 \longrightarrow 10$	39336.6	0
39320.5	$10 \longrightarrow 12$	39320.5	−0.1
39304.4	$12 \longrightarrow 14$	39304.4	−0.2
39288.4	$14 \longrightarrow 16$	39288.4	−0.2

Here the spacing of the lines is 16.0 ± 0.1 cm.$^{-1}$ If we assume that alternate rotational levels are missing, and that the electronic bands effective in the phenomenon—in this case the so called $X \longrightarrow a$ ${}^1S \longrightarrow {}^1P$ bands (H. Sponer, *Proc. Nat. Acad. Sci.*, **13**, 100, 1927) consist only of a P and R branch, we deduce for N_2 in the normal state $h/8\pi^2 c I_0 = 2.00 \pm 0.01$ cm.$^{-1}$, which gives for the moment of inertia

$$I_0 = 13.8 \pm 0.1 \times 10^{-40} \text{ gm. cm.}^2$$

We have, so far as I know, no data on which to check this result, but the value seems reasonable. If we had not assumed alternate levels to be missing, we should have found half this value, which is evidently too small.

The measurements in this case are accurate enough to extrapolate the position of the first rotational line. The calculated values in the table are obtained from the formula

$$\Delta\nu = 2.00\,(4m+6), \qquad m = 0, 2, 4, \ldots$$

using for m only *even* integral numbers. As satisfactory an agreement as this could not be obtained with a slight change in the constant 2.00 and the use of odd values for m.

So, on the whole, this seems to give support to the hypothesis that in the normal state of N_2 only even rotational states are present, or, at least, they have a higher statistical weight than the odd ones. An investigation of the structure of the $X \longrightarrow a$ ultraviolet bands of N_2 would show whether these deductions are correct.

Now, I think we can explain the, at first, rather puzzling fact, that the Raman lines corresponding to vibrational transitions in N_2 and O_2 (respectively 2331 cm.$^{-1}$ and 1554 cm.$^{-1}$) show no rotational structure, but, even with the higher dispersion of the quartz spectrograph, appear as single lines. We have, of course, all the allowed rotational transitions ($m \longrightarrow m+2$, $m \longrightarrow m$, $m \longrightarrow m-2$, for example, in O_2), but we must consider that each of those involving a change in m gives a *different* line; instead, when m is unchanged, the position of the line is nearly independent of m, because of the *very small* change in the constant $h/8\pi^2 I$ between the zero and the first vibrational state. So the line given by *all* the transitions $m \longrightarrow m$ has a very high statistical weight, and is practically the only one observed.

I have obtained, also, the Raman spectrum of gaseous hydrogen. It gives two lines excited by $\lambda 2536$, shifted by 583 cm.$^{-1}$ and 4159 cm.$^{-1}$ respectively. These have already been found in liquid hydrogen and explained by McLennan.

I will make a last remark concerning the Raman spectrum of carbon dioxide. In a recent letter to NATURE (Feb. 9, 1929) I pointed out that the frequency observed in the Raman effect, $\nu = 1284$ cm.$^{-1}$,

is practically coincident with the difference between two frequencies observed in infra red absorption Now, I notice that Eucken (*Zeit f Phys*, **37**, 714, 1927), in his theory of the straight line model of the carbon dioxide molecule, assumes the existence of an 'inactive' frequency, $\nu = 1274$ cm $^{-1}$, and the validity of the above mentioned relation, at least to a first approximation Thus the data on the Raman effect give strong support to Eucken s model of the carbon dioxide molecule F RASETTI

Floating Mercury on Water

IN a letter in NATURE of Mar 16, Mr N K Adam describes the floating of small globules of mercury on a water surface, even when the latter was considerably contaminated He concludes that for equilibrium to be possible, the mercury air tension must have been reduced by the order of one or two hundred dynes It is not necessary to suppose such a decrease It appears that the part played by curvature of the surfaces in determining conditions for the equilibrium or the spreading of one liquid on another has been neglected Experimentally, we have the observations of Burdon (*Proc Roy Soc*, **38**, 2, 154 1926), who found that water would spread over the surface of a large, clean mercury drop, but that its progress was stopped when the curved edge of the drop was reached where acceleration 'downhill' would be expected

The familiar criterion for spreading is derived sometimes from the consideration of the three 'tensions' involved and the possibility of constructing a Neumann triangle, but more often from the point of view of surface energy Spreading will occur if the advance of the liquid brings about a decrease in the total surface energy Let T_1, T_2, T_{12} be the tensions involved, and let the increase in area when the liquid 1 advances a small distance A to B be S (Fig 1*a*) The increase in energy is then $T_1 S + T_{12} S$ and the decrease is $T_2 S$ Then for spreading, $T_2 S > T_1 S + T_{12} S$ or

$$T_2 > T_1 + T_{12} \tag{1}$$

But suppose now that the surface of the lower liquid 2 is curved, as in Fig 1*b* Here the decrease in energy

FIG 1

is still $T_2 S$, but the increase is now $T_1 S' + T_{12} S$ —where S', the increase in area of the liquid air surface of 1 is *not necessarily equal to* S Then the condition for spreading becomes

$$T_2 > T_{12} + T_1 \frac{S'}{S} \tag{2}$$

If S' is greater than S, it is quite possible that even if condition (1) is fulfilled, that is, spreading occurs on a plane surface, (2) is not, spreading is stopped by the curvature

Using the figures given by Mr N K Adam for the uncontaminated liquids, spreading would be stopped if the ratio S'/S were greater than 1 4 1, so that spreading may have been stopped by the curvature (0 5 mm. diameter) without the considerable lowering of the tension stated

Yet for the curved surface as for the plane, the condition that the Neumann triangle cannot be drawn is still (1), and from the point of view of the equilibrium of tangential forces at the interfaces, it is difficult to see how curvature can enter into the problem It seems to me that this is another indication of the many that the conception of three tangential forces at a point—and of Neumann s triangle—is wholly inadequate to represent the forces involved in capillary phenomena

It may be noted that in Coghill s work on lenses of oil floating in water (*Tech Paper* 262, Bureau of Mines, Washington 1923) the measured interfacial angles did not agree with those calculated from the Neumann triangle

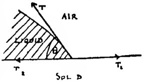

FIG 2

It must have been often remarked that in the case of a liquid in contact with a solid for example, the three tensions alone are to any student of elementary mechanics not in equilibrium though few text books mention that other forces have been omitted or explain what these forces are If the 'tensions' do not give an adequate representation here, why can we assume that they are sufficient in other problems? Theoretically unsound, the Neumann triangle has no experimental usefulness—and the spreading coefficient used by Hardy and Harkins is limited in its application to plane surfaces

(A C BURTON

University of Toronto
April 5

IN a letter appearing in NATURE for Mar 16, Mr N K Adam describes floating mercury droplets These droplets are minute (0 5 mm in diameter), and Mr Adam evidently regards them as fluid throughout supported by the surface tension of the water

In a letter to NATURE for July 2 1903, p 199, I described the production of mercury bubbles floating on water These might be any size up to 2 cm in diameter and were supported not by surface tension but by flotation, as might be seen from the fact that they floated even when the water film was continuous over them Measurements of the weights of mercury forming those bubbles and estimations of the thicknesses of their skins were given

Trinity College, Dublin, Mar 17

Hibernation of *Lucilia sericata*, Mg

SINCE the hibernation of the Muscidæ affords such general interest, it is felt that recent observations on this phenomenon as exhibited in the particular species *Lucilia sericata*—the most important entomological pest of sheep in North Wales—are worthy of note

It should be explained that my interest in the hibernation of *Lucilia sericata* arose as a result of a survey of Maggot Flies attacking sheep in North Wales in 1928, which showed that *sericata* was the only species concerned

All larvæ used during these observations were taken by farmers direct from infested sheep When received, at almost daily intervals throughout the season, they were placed in the insectary in cages containing a piece of fresh meat on soil From May 5 until Sept 8, the period which elapsed between the receipt of the larvæ at the laboratory and the date of emergence was fairly constant—on the average 21 days The majority of the larvæ received on Sept 8 and 10, however, had not pupated by Oct 10 Instead, many remained quiescent in the soil at the bottom of the cages, while

others had entered empty pupa cases Further, it was noted that not a single larva of the ten subsequent batches—the final batch being received on Oct 27—had pupated

On Oct 15, 720 such larvæ received from various sources, were available for hibernation observations and were used in the following experiments Six earthenware pots, 5 inches deep, were filled with soil and closed above with muslin four represented arable conditions, while two had turf placed on top of the soil to create a grassland environment One of the grass land pots and two of the 'arable' pots were placed in the laboratory, while the duplicates were sunk in the soil out of doors, the rims of the pots being at ground level 120 larvæ were allowed to drop on to the sur face in each of the pots all had burrowed out of sight in about 15 minutes A week later larvæ were found at the bottom of each pot

Periodic examination of the out of door pots showed that the larvæ remained thus buried and in a quiescent state throughout the winter, the mean daily tempera tures (taken just above the pots) for the months con cerned being Oct, 59 85° F Nov, 51 09° F Dec, 43 58° F, Jan, 41 77° F Feb, 43 76° F Mar 52 98° F April, 57 3° F

On Feb 14, with a minimum temperature of 16° F, the soil was completely frozen, yet the quiescent larvæ when disturbed proved to be viable No activity was observed in the pots until the period Mar 20–26 (mean daily temperature, 53 86° F) when it was noticed that the larvæ were making their way towards the surface They eventually came to rest at a level approximately ½ in below the surface On April 2 the first pupa was found, and by April 10 the majority of the larvæ had pupated The first fly emerged out of doors on April 27

Observations on the indoor series gave similar data except that the flies emerged at an earlier date the first being found on April 10 The mean temperature throughout the winter was more or less constant at 51° F (since the last week in March it has risen about 9°) The humidity was maintained by daily watering of the pots

The hibernation of *Lucilia sericata* has not so far as I am aware, formed the special study of a previous worker Mention is made in some works of the difficulty experienced in getting the larvæ to pupate in the autumn, but there is no suggestion that the insect overwinters in the larval stage Records from S Africa and New South Wales show that adults have been trapped throughout the year while in the United States research has indicated that *sericata* overwinters in the larval and pupal stages

From the observations here mentioned it would appear that the normal mode of hibernation of *Lucilia sericata* in North Wales is in the larval stage Further while the return of the larvæ to the surface after overwintering and prior to pupation obviously facilitates emergence, it should be pointed out that at this time they are more open to control methods than at any other stage after leaving their host

Cosmic Radiation and Radioactive Disintegration

DR L R MAXWELL, in NATURE of Dec 29, 1928, gives an account of experiments intended to show the influence of cosmic rays on the speed of radioactive disintegration of polonium According to Perrin, the radiation may be regarded as a possible cause of radioactive changes The detailed study of cosmic rays, carried out lately by numerous investigators, and the determination of their probable wave lengths, combined with the ideas of Perrin, involun tarily led us to think that the cosmic rays may be the real cause of radioactive processes The frequency of cosmic rays is of such magnitude that their quanta ought to be sufficient to disintegrate the nucleus

At our request, Mr E Halfin, in June of 1926, per formed some experiments with radon analogous to those of Dr Maxwell The activity of two nearly equal quantities of radon was carefully measured, and thus the exact value for the ratio of the activities of two chosen samples was obtained Immediately after, one sample was let down to the bottom of the Gulf of Finland to a depth of about 20 feet and the other sample was left in the laboratory After several days the first sample was taken out and the comparison of the activities of two samples was repeated in the laboratory These experiments have shown that, within the limits of possible errors, the speed of disintegration of the sample of radon which was kept under the water did not appreciably change The error of the corresponding measurements in any case did not exceed 1 per cent Our experiments with radon and Dr Maxwell's experiments with polonium show that the cosmic rays do not affect in appreciable degree the speed of disintegration of either radon or polonium These facts lead us to the conclusion that the disintegration of the two elements investigated is not at least entirely, due to the action of cosmic rays

It would not be correct though on this ground, to deny any influence of the rays on radioactive pro cesses As a matter of fact, the total intensity of the cosmic radiation is so small that it is quite possible that it affects in some way a very minute number of radioactive atoms and its action cannot be detected especially in the cases of radioactive atoms of short life

The cosmic rays, furthermore, may perhaps give a start to the disintegration process in the radioactive family and actually cause the disintegration of the first element in the family, for example, uranium Experiments with this element (observation of the growth of activity of uranium X_1) might throw some light on the last question In this case the total intensity of cosmic rays might be sufficient to account for the radioactive process, as the number of atoms of uranium which disintegrate in unit time is very small

The Structure of the CH_4 Molecule

IN a recent investigation of the ionisation processes in methane, Hogness and Kvalnes (*Phys Rev*, 32, December 1928), using a mass spectrograph method find that at 14 5 volts only CH_4^+ ions are formed, but at 15 5 volts two processes occur, either stable CH_4^+ ions are formed or unstable CH_4^+ ions which dis sociate spontaneously into CH_3^+ ions and neutral hydrogen atoms, the probabilities of the processes occurring being approximately equal over a wide range of pressure

Two models have been proposed for the CH_4 molecule, one having a C^4 central ion of neon like character, the other having a C^{4+} central ion, but neither of these models will explain the results quoted above If the four chemical bonds in methane con sist of pairs of shared electrons, each pair being formed by an L electron of the carbon atom and a hydrogen

electron, then a simple explanation can be given, for since there are two 2_1 and two 2_2 electrons in the carbon atom, two of the bonds will differ from the other two, that is, two of the pairs of electrons will be differently bound from the other two Two ionisation potentials would therefore be expected having approximately equal probabilities of excitation This assumes that the ionisation potential of either of the two electrons forming a bond is the same That two of the bonds in methane differ from the other two is in agreement with Mrs Lonsdale's view that the carbon atom has two different kinds of valencies (*Phil Mag*, **6**, p 433, 1928), and is also supported to some extent by the observation of Cabannes and Gauzit (*Jour de Phys*, **6**, p 182, 1925), that methane has a small depolarisation factor, an indication of small optical anisotropy Experimental evidence also tends to show that models of the methane molecule having either a C^{4-} or a C^{4+} central ion are incorrect (cf T H Havelock, *Phil Mag*, **3**, p 444, 1927, **4**, p 721, 1927)

The Constitution of Oxygen

DR F W ASTON has remarked (NATURE, **123**, 488, Mar 30, 1929) that he finds no positive ray evidence for the existence of isotopes of oxygen, and he states that if O^{18} exists, as concluded by Giauque and Johnston (NATURE, **123**, 318 Mar 2, 1929), it must be in a proportion less than 1/1000 of O^{16}

Giauque and Johnston based their result on data published by Dr Dieke and myself (*Proc Nat Acad Sci*, **13**, 670, 1927) Further evidence bearing on the question has now been found, confirming the existence of O^{18}, and also the limiting proportion set by Aston From spectrograms made with low solar altitude it has been possible to augment the A' band of oxygen from 26 lines, as formerly described, to 73 lines About one half of these belong to the alternate system of doublets which are to be expected from the unsymmetrical molecule O^{16}–O^{18}, while the rest of the new lines are extensions of the previously recognised system of doublets The observed positions of the lines of this band agree with those calculated for the isotopic molecule, and the new data thus decisively confirm the existence of O^{18}

Intensities of the isotopic band lines have been compared with those of homologous lines in the A band by so choosing the lengths of air path as to make the two bands appear alike when registered with the same spectrograph From the ratio of the air paths it was found that the A band is 1250 times as intense as the A' band, and, approximately at least, this represents the relative abundance of the molecules O^{16}–O^{16} and O^{16}–O^{18} More complete discussion will be found in a forthcoming paper in the *Proceedings of the National Academy of Sciences*

Selective Absorption by Excited Mercury Vapour

OUR attention has been directed to a paper by M. M Ponte on the selective absorption by excited mercury vapour (*Comptes rendus*, **187**, 37 39, July 2, 1928) giving results of photometric measurements on the prominent lines in the arc spectrum of mercury M Ponte refers to a paper by us on the same subject (*Proc Roy Soc*, A, **100**, p 149, 1921), but does not notice a paper by Turner and Compton (*Phys Rev*, **25**, 606 612, 1925) He finds that the absorption diminishes as the current term number of the line in a series exhibiting absorption increases, a similar result has been recorded by Turner and Compton (loc cit)

In the latter part of his paper, M Ponte records his observation of the reversal of the green line and six of its satellites and of 4358, but not of the two yellow lines In this connexion we have to point out that in a paper published by us in 1924 (*Proc Roy Soc*, A, **105**, 520 531), not referred to M Ponte, we have described, among others, experiments proving the reversal of the green line and all its satellites except one, namely, − 0 237, of the line 4358 and four of its satellites, of the two yellow lines, and two of the satellites of 5769, namely, + 0 044 and − 0 050 The device of using the broadened lines from a high pressure source as a background for the formation of the reversal lines produced by an absorbing column at low pressure suggested by M Ponte has been mentioned by us in the same paper M Ponte's method of exciting the absorbing column by maintained high frequency oscillations is of special interest

Raman Effect in Atomic Hydrogen

IN the paper on the dispersion of hydrogen like atoms published in the *Proc Nat Acad of Sci*, **14**, 253 (1928), I have obtained a solution of the Schrodinger wave equation, for a hydrogen atom in the field of radiation of frequency ν, of the form

$$\psi = e^{2\pi i E t/h}[\psi_0 + e^{2\pi i\nu t}u_1 - e^{-2\pi i\nu t}u_2],$$

where ψ_0 is the solution of the unperturbed equation, while u_1 and u_2 are small quantities which are functions of co ordinates only

The Raman effect for atomic hydrogen comes out of this solution naturally If one calculates the matrix elements corresponding to components of the electric dipole moment, one obtains terms containing factors $\exp\ 2\pi i(\nu - \nu_1)t$, $\exp\ 2\pi i(\nu + \nu_1)t$, and $\exp\ 2\pi i\nu_1 t$ respectively, where ν_1 is the frequency of absorption lines In addition to the ordinary transitions, the transitions with a change of azimuthal quantum number by ± 2 are now permitted Details of the investigation will be published elsewhere

Ozone Absorption during Long Arctic Night.

A LETTER from Prof R W Wood on this problem (NATURE, April 27, p 644) calls for some comment Prof Wood's contention that my observations of ozone absorption in December last (cf NATURE, Feb. 9, p 207) are not decisive because the atmosphere above my station was sunlit at noon, overlooks the important fact that *this sunlight had all been filtered through the atmosphere, and at grazing incidence, such as to have its activating constituents effectively removed* On account of the crude equipment the results are, however, provisional in nature, and this and allied problems will therefore be pursued next winter with an improved telescope

Iron Manufacture and Heat Generation[1]

By Prof HENRY LOUIS

THE date and even the place of the first use of iron by mankind have never been determined, it appears to be generally held that iron was first produced in workable quantity on the southern flanks of the Caucasus, and the date assigned is usually somewhere about 3000 B C, though for my purpose both the place and the exact or even the approximate date are matters of secondary importance My main object is to indicate that the history of iron manufacture shows it in the light of a consequence of the ever-increasing power which mankind gradually learnt to exercise over the production of heat, and I hope to be able to show that the history of iron and the history of heat generation have gone hand in hand throughout the ages, and that the former has been absolutely dependent upon the latter It is certain that, before iron came into use, the metallurgy of bronze was already highly developed Articles of bronze of the Later Bronze Age show that the art of bronze founding had already reached a high stage of perfection The art of making cored castings was undoubtedly known, and it seems probable that even the *cire perdue* process had been invented

No doubt the simple reduction of metallic iron from its ores would have been well within the capabilities of these primitive metallurgists, but from the simple reduction of the metal to its fashioning into any useful form is quite a far step Oxide of iron is reducible to the metallic state at a very low temperature, not exceeding 500° C, but the iron so produced is more or less pulverulent and useless for all practical purposes To weld it into

FIG. 1 —Blowing up the fire by the mouth blowpipe (Egypt). From Wilkinson's 'The Ancient Egyptians'

a coherent mass capable of useful application requires not only a considerably higher temperature, but also for articles of any size a considerable body of heat, and this would apply equally to the forging of meteoric iron The only information that we have as to the early means of producing the necessary heat is derived from Egyptian mural paintings All the earlier ones—for example, one from the frescoes of Beni Hassan (Fig 1), said to date from about

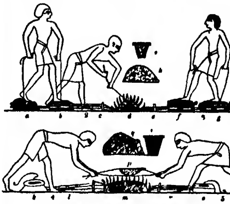

FIG 2 —The earliest known form of bellows (Egypt) From Wilkinson's "The Ancient Egyptians

k and *o* are raised as if full of air

2500 B C —show men blowing up a fire beneath a crucible by means of mouth blowpipes made of reed and tipped with clay, and it is evident that with such rudimentary appliances only very small pieces of iron could be produced

The first known representation of any mechanical means for producing a blast is from the walls of a tomb of the period of Thothmes III, supposed to be from about 1500 B C This primitive bellows (Fig 2) apparently consists of a flat pot covered with skin, in the centre of which is cut a hole that can be closed at will by the heel of the operator, which thus forms a valve, the skin, when released by the heel, being pulled up by a cord in the worker's hand It is interesting to note that this identical type of bellows is still used in India by certain tribes for the purpose of iron manufacture, the only improvement in more than 3000 years being the use of a couple of light bamboos which act as springs to pull up the hide cover A photograph of a native lad working these bellows (Fig 3), taken a few years ago by the late Mr Seymour Wood, shows the method, moreover, these bellows have been figured in full detail by Dr John Percy in his classical work on the "Metallurgy of Iron and Steel"

The position at a tolerably reliable date can be well estimated from the British Museum excavations at Djerabis on the Euphrates (the Charchemish of Biblical times), as recorded in Biblical writings, this place was attacked and captured by Nabuchadnoser, King of the Babylonians, in 604 B C The finds consisted of broken swords and spear-heads, all of bronze, and of numerous arrow-heads, both of bronze and of iron; there was also found a beautifully finished bronze mould

[1] From the presidential address delivered to the Iron and Steel Institute on May 2.

for casting the bronze arrow heads, and it is particularly noteworthy that these bronze arrow heads are far superior in execution and finish to the iron ones—the iron ones being all tanged, whilst most of the bronze arrow heads are socketed

It is therefore evident that at this date, even in the centre of the highest civilisation of the time, skill in working iron had not reached anything like so high a level as that of the bronze worker, the finds are, of course, not conclusive evidence that no larger weapons of iron were in use at the time, but I think that the conclusion may fairly be drawn that they must have been far scarcer than the bronze weapons, and that the difficulty of working even moderately large pieces of iron had by no means been fully overcome, and that whilst small articles of iron could be made readily enough, there must still have been difficulty in producing the larger articles which required a considerable body of heat This emphasises the essential point which I want to bring out, that the means of generating the requisite heat must have been the controlling condition in the manufacture of iron Furthermore, as is well known, whilst iron reduced at a low temperature, even from impure ores, is sufficiently pure not to be brittle, it must necessarily be very soft, and it may readily be supposed that a well made bronze sword was for quite a while superior to a soft iron one This difficulty must have persisted until a much later date in northern Europe, since the Norwegian sagas more than once record that a warrior had a sword so soft that he had to stop to straighten it underfoot in the course of the conflict

On the other hand, it is quite certain that in the countries bordering on the Mediterranean, where the knowledge of metallurgy was much older and civilisation was much further advanced, temperatures high enough to cause some carbon to combine with the iron and thus make relatively low carbon steel or steely iron had been attained at a very much earlier date, as is evident from the oft quoted passage in Homer's Odyssey, from this it is obvious that steel or steely iron capable of being hardened by quenching was known in Homer's time, though the carbon content could not have been excessive, seeing that the metal so treated was not too brittle to prevent its being used as an axe, yet there must have been enough carbon present to cause perceptible hardening by quenching, seeing that Homer states that such quenching gives strength to the iron On the other hand, Homer's frequently repeated epithet for iron "wrought with much toil" shows that the manufacture of iron was still in an elementary stage, it will be remembered that Homer certainly wrote before 800 B C

It could, however, not have been very long after the beginning of our era before, with the employment of larger furnaces and, therefore, the production of a greater body of heat, a true steel was produced, and this would, of course, be the case more readily when manganiferous ores happened to be employed instead of ordinary iron ores Thus both Horace and Ovid refer in their poems to the high quality of Noric iron The Noric kingdom corresponded to the region now known as Styria and Carinthia, and it is quite probable that this Noric iron was made from manganiferous spathic iron ores of the Styrian Erzberg of Eisenerz Jars, who visited the Erzberg in 1758, directs attention to the fact that steel was readily produced by smelting certain of these ores Similar ores appear also to have been worked in Spain, and they, too, must have produced steel or steely iron, and we have evidence that some at any rate of this material consisted of iron combined with sufficient carbon to be capable of being appreciably hardened by quenching It must be remembered that the above statements as to the use of iron refer only to the region which at that early date was the centre of human civilisation, it is generally held that iron was not introduced into Britain until 500 B C, and that its manufacture did not commence in these islands until about a century later

FIG 3—Bellows as used in India

Before Cæsar's invasion, iron was certainly being made in the south of England, though the Brigantes in the north appear still to have been in a Stone Age Before Cæsar's time, iron currency bars were in use in southern Britain—a fact which would seem to imply that, although iron was being made, it was still scarce and comparatively valuable The manufacture of iron continued in Britain throughout the Roman occupation The largest

mass of Roman iron found in Britain, if not in the world, is the mass discovered at Corstopitum, near Corbridge, in Northumberland, described by Sir Hugh Bell Its date is considered to be between A D 350 and 380, and its weight was about 3 cwt It is quite clear that the method of iron production throughout all this period was always the same—namely, direct reduction by charcoal in furnaces probably not more than 3 ft or 4 ft high, and blown by bellows worked by man power, in which the temperature was only high enough to produce soft malleable iron, or, at the best, with suitable ores a steely iron or a steel Apparently this method of iron making must have continued during the next thousand years or so, probably furnaces were steadily increasing in size, larger lumps of iron were being made, and probably steely iron or even steel was produced at will The art of letting down or tempering steel must also have been discovered, and the technique of iron working, as distinct from the extraction of iron, made immense strides

An invention that must have contributed no little to the increase in the size and power of the medieval furnace was that of mechanical blast production Agricola, whose well known work is dated 1556, figures and describes in much detail the construction of a bellows with valves of quite modern type, worked by a water wheel, and it is on record that such bellows were in use at Göllnicz in 1435 A natural result of the increase in the height and power of the furnace and of the attendant higher heats thus generated was the production of white cast iron, and it is tolerably clear from Agricola's writings that this was known in his day No doubt this unexpected result of the higher furnace temperature must have been a disagreeable surprise to the early metallurgist, who found in his furnace a lump of this hard, brittle, useless material instead of the mass of malleable iron or steel which he hoped to produce In the course of time, however, he would discover that this useless metal could have its pristine malleability restored to it, or, as he expressed it, the iron could be 'freshened' by heating it in another (or possibly the same) furnace When this technical stage had been reached, the iron-worker no doubt soon learnt to appreciate the advantage of a continuous process in which the metal could be made to flow out from his reduction furnace, over a discontinuous process in which the lump of metal had to be dragged out of the furnace either by tearing down the furnace front or by lifting the lump bodily out of it This step would lead to a still further increase in furnace and bellows capacity, and this in turn would bring about a further increase in furnace temperatures, with the again unexpected result of producing grey cast iron, as soon as the temperature became high enough to reduce sufficient silicon It would soon be found that such iron ran very fluid and was admirably adapted for making castings

Apparently one of the very earliest forms of iron castings was the iron stove plate, which originated in Germany The oldest known cast-iron stove plate is dated 1497 and was from the Eifel, which appears to have been one of the earliest centres at which castings of this kind were made No doubt it took the early founders some time before they learnt to adapt their bronze-founding technique to this new material, very much in the same way as in our own time iron-founders have had to learn to modify their methods for the successful production of steel castings, but the superior qualities of articles made of cast iron would be a sufficient incentive to urge these early workers to find out how to overcome their difficulties Once this was done, a demand for such pig iron would arise and the blast furnace making charcoal iron was evolved The next step was the substitution of coke for charcoal, thus attaining the production of still higher temperatures, it is, by the way, interesting to note that the first coke furnaces still used bellows worked by a water-wheel, just as in Agricola's time, and that these continued in use up to the middle of the eighteenth century About that date they were, however, replaced by iron blowing cylinders, capable of generating a more powerful blast, and therefore, of producing higher temperatures, whilst Neilson's invention of the hot blast in the year 1828 enabled still higher temperatures to be attained in the blast-furnace

The next stage was the production of mild steel in the Bessemer converter and the Siemens open hearth furnace, to be followed by the important modification of Thomas and Gilchrist, which we know as the basic process Necessarily, these processes involved the use of still higher temperatures than had hitherto been attained and finally we reach the production of alloy steels in the electric furnace with its capacity for generating still higher temperatures

I do not wish to imply that each one of these successive stages immediately and definitely put an end to all use of the earlier processes Quite the contrary is the case, for there are many examples of the old and new methods working side by side Even to day in India and in many other similar countries the direct process is still in use Again, although Abraham Darby successfully made pig iron with mineral fuel so far back as the year 1735, charcoal blast furnaces are still in operation in Sweden and various other parts of the world, and there was even one still at work in Great Britain at Backbarrow, near Ulverston, until Dec 17, 1925 In spite, however, of this overlapping of processes and of the survival of the older methods alongside of newer ones, the line of progress is quite unmistakably defined

It will, I hope, be admitted that this rapid review of the history of iron manufacture is correct, at any rate, in its main features, and that my contention that the power to produce high heats has throughout been the controlling factor, is well founded, I want to make it clear that I consider that the various stages of iron manufacture and of the generation of ever higher temperatures are not two independent concurrent parallel lines along which the development of human civilisation has

travelled, but that they are distinctly related as cause and effect This being true of the past, what can we say as to the future ? Just as there is a lower heat limit below which iron capable of being usefully applied in the arts could not be produced, so there must be an upper limit, and I suggest that this limit is reached when our furnaces are capable of generating a temperature sufficient to volatilise the iron, it seems fairly obvious that heats higher than this cannot well be usefully employed Such heats are, however, now readily attained in the electric furnace and it would therefore seem that from this point of view the limiting condition has already been reached by the metallurgist On the other hand, there seems but little inducement to increase the quantity of output, seeing that our potentialities of production appear to be now actually ahead of the world's requirements, and that there is every indication that even our present appliances will enable us to keep pace with any future demands

I emphatically do not mean to imply that we have reached finality in the metallurgy of iron, but I do hold that future progress will have to be along different lines Fortunately, we are already able to see what direction this progress must take Recent advances have all been in the direction of improvement in quality and in the attainment of properties in which ordinary iron by itself is deficient In other words, the future of the metallurgy of our metal will be directed, not by the crude methods of trial and error of the past but by the application of principles developed by the methods of scientific research For something like four centuries Great Britain has led the way in the great improvements in the iron industry along the old lines which I have been describing, we are however, also the inventors of the science of metallography and of alloy steel, we may therefore, fairly claim that even in modern scientific methods we are equally leading the world in the metallurgy of iron, and there is every reason to presume that the great work which members of the Iron and Steel Institute have done in the past in developing that iron industry which is the basis of our modern civilisation will still continue in the future although, as I have suggested, that work will be carried on by means of modern methods and be based upon entirely different principles

Progress of the Great Barrier Reef Expedition

By Dr C M Yonge, Balfour Student, University of Cambridge

IN the three months which have elapsed since the last report, the work of the Great Barrier Reef Expedition, in all its branches, has made excellent progress Naturally, the weather conditions have not been so favourable as they were in the winter, heavy rains and humid heat, with wet bulb readings so high as 86° F, have been experienced, but work has been interfered with far less than was anticipated The most serious drawback has been the state of the tides, the day low tides being very poor, which necessitated much collecting by night On the other hand, sea work has proceeded without a hitch in spite of the previous gloomy accounts of the storminess of the summer months

A great loss has been experienced in the departure from Low Island on Dec 12 of Mr and Mrs F S Russell and Mr G Tandy, who were compelled, owing to the termination of their leave of absence, to return to England Dr T A Stephenson has succeeded Mr Russell as second in command, while Mr A P Orr has taken over charge of the boat party, Mr J S Colman carrying on Mr Russell's work on zooplankton There is, unfortunately, no professional botanist to succeed Mr Tandy, though Miss Glynne is expected for two months later in the year, meanwhile Mrs Stephenson is doing what she can to continue the collection of algæ Mr. M Spender, of the geographical section, is now with us permanently, while Miss E A Fraser, of University College, London, and Dr S M Manton, of Cambridge, join us shortly Both will work in co operation with the reef party under Dr Stephenson

The regular plankton and hydrographic observations at the station 3 miles east of Low Island have been continued with scarcely an interruption, a further station has been worked in Trinity Opening, all from the *Luana*, while on two occasions the powerful motor launch *Merinda* has been hired from Cairns for work beyond the Barrier For the hauling in of nets and hydrographic gear from deep water a friction winch with a small motor has been purchased, and this renders work both easy and relatively speedy

At the inside station Mr Orr reports that temperature has risen steadily to 29° C at the surface and 28 8° C in deeper water, while salinity has fallen and continues to fall as a result of the heavy rains On several occasions there has been a definite gradient in temperature and salinity, accompanied by a fall in oxygen saturation in the deepest layers, though without any production of phosphate, but this has never lasted more than a week at a time or ever been considerable enough to withstand a wind of more than 20 miles per hour The hydrogen ion concentration has remained steady throughout Observations made at a depth of 600 metres beyond the Barrier showed that temperature was constant down to 50 metres, beyond which it fell rapidly to 10 9° C at 600 metres Below 50 metres, pH value and oxygen saturation sank and phosphate content rose On Linden Bank, a coral formation beyond the Barrier and covered with 34 metres of water, the conditions were very similar to those inside the Barrier The turbidity of the water is far less beyond than within the Barrier

Miss S M Marshall and Mr Colman are continuing routine work on the phytoplankton and zooplankton respectively As the lack of nutrient salts in the water indicates, there has been no

significant change in the numbers of the phyto plankton within the Barrier, while the numbers have been found even smaller in the open sea stations, there being little difference in type save for a few oceanic flagellates rarely found inside The only notable change observed in the zoo plankton occurred during the three weeks at the end of November and the beginning of December, when spatangid plutei appeared quite suddenly in vast numbers, the coarse silk townet catching just under 300,000 in a half hour haul It may be noted that dredging has revealed the presence of great numbers of a species of *Lovenia* in the mud around Low Island, one haul of the Agassiz trawl bringing in a catch estimated at about 20,000 Salps and Larvacea continue to fluctuate in an apparently irregular manner, and also copepods, which usually comprise numerically more than half the catch On one occasion when planulæ were being extruded from *Pocillopora* on Low

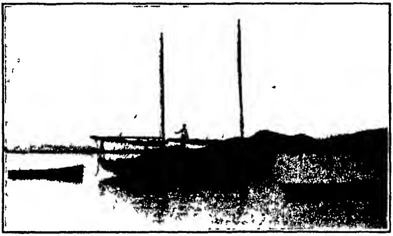

FIG 1 —The *Luana* at anchor between Snapper Island and the mainland

Island, some 3000 similar planulæ were caught in the coarse silk net Again, on another occasion the numbers of *Cavolinia* rose from an average of less than 50 to 1200

Work over the reef flat by members of the boat party has been continued Mr Orr made a de tailed study of a coral pool at spring tides, and found that, though there were very considerable changes in the hydrogen ion concentration, excess base, and temperature, there was no precipitation of calcium There was a very low night tide and the oxygen saturation fell to 18 per cent, rising during the day to 230 per cent In the mangrove swamp the oxygen content and pH value fell both by day and night during the low tides, instead of only during the day as in the coral region Miss Marshall finds that the numbers of the phyto-plankton in the anchorage remain low, such slight fluctuations as there are being without apparent cause The zooplankton collected by Mr Colman weekly has become progressively poorer in num bers and variety, though spatangid plutei and *Cavolinia* appeared at the same time as at the three-mile station

Other work by members of the boat party has included the exposure, by Mr Orr, of jars for the collection of sediment, in selected areas on the reef flat and in the lagoon These are collected weekly, and show clearly that the quantity of sediment is dependent on wind force and on the position of the jar, the sediment being mainly organic detritus mixed with some sand after stormy periods The results from the various jars have so far been quite consistent and lend no support to the theory that abundant sediment is inimical to coral growth Miss Marshall has done interesting work on the oxygen exchange of the planulæ of *Porites*, and found that, though their algæ produce a considerable amount of oxygen even at this stage, this does not balance the loss of oxygen due to respiration, also that more is pro duced in sunny than in dull weather

Dr T A Stephenson has completed a new type of experiment for observing the growth rate of corals By the aid of the diving helmet, a number of colonies have been marked in particular ways *in situ*, working in about 12 20 feet of water It may be suitably mentioned here that this helmet has proved of great value, parti cularly in connexion with Dr Stephenson's work, but also in the collection of Mr Orr's sediment jars and of corals for experi mental purposes Dr Stephen son has continued his routine observations on the gonads of *Favia* and *Symphyllia*, and has made further progress with the ecological survey Both *Pocillo- pora* and *Porites* have given off abundant crops of planulæ, num bers of these have been collected and reared, detailed observations being made as to the formation of young colonies from settled planulæ He has been engaged on manifold constructional activities on the reef flat, particularly in connexion with the rearing and collection of planulæ and the observation of the spawning of reef animals He has also made a new aquarium consisting of concrete tanks through which water runs continuously, this being parti cularly useful in connexion with Mrs Stephenson's work on the reproduction of reef animals, which has been continued on the lines previously re ported and also extended by the examination of various kinds of spawn collected on the reef

The work on animals of economic importance now occupies practically the entire time of Mr F W Moorhouse Although his farm of *Trochus* was unfortunately destroyed by stingrays, the previous six months had shown that the average increase in diameter of specimens ranging from 2 cm to 6 cm was no less than 2 mm per month, giving a yearly increase of about 2 5 cm Growth is continuous, and no disturbance rings are found on normal shells He has been able to confirm these figures by the measurement at each full

moon of some 600 animals taken at random, the measurements being graded into groups of 0 2 cm and the results recorded graphically He has now 360 sponge fragments planted out Some are suspended from lines, others are confined in 'houses' to test the effect of the elimination of direct sunlight Regeneration of the fragments is remarkably rapid, the supporting cord being overgrown completely or partially in two days and the whole cut surface being overgrown in ten days The growth rate of the local oysters is being studied, while weekly gonad examinations of *Trochus niloticus*, *Holothuria atra*, and two species of edible oyster have been made regularly, artificial fertilisations being successful in all save the first He continues to take the temperature of the water in the anchorage twice daily, and this has risen as high as 33° C, very near the lethal temperature of corals During the recent low spring tides the temperature over the flat has risen above 35° C and a great many corals have been killed

Assisted throughout by Mrs Yonge and Mr A G Nicholls, I have been able to make very material progress with my work Little further work has been done on the feeding mechanisms of corals, but it has been found that *Favia* and *Galaxea* can digest planktonic organisms of 2 3 mm in length completely within twelve hours The symbiotic algæ of corals possess a well developed cellulose wall, have extensive reserve of fat, but no pure starch A number of suitable corals have been fed with a variety of substances and polyps fixed after appropriate intervals with suitable fixatives, for the later determination of the site and mode of absorption

FIG 2 —Interior of laboratory Plankton bench on left chemical bench in centre director s bench on right

The monthly experiments on the change of oxygen content in the water surrounding corals kept for similar periods in light and darkness have been continued, and confirmatory experiments on the length of time which corals can survive sealing in jars in the sea have been carried out A large light tight box with a detachable lid, containing a small trap door, has been cemented down on the reef flat, the object being to obtain data on the effect of continued darkness on the oxygen content and hydrogen ion concentration of the water surrounding the corals and clams (which also contain algæ) placed in the box

Work on the digestive enzymes of corals has been almost completed; extracts of the mesenterial filaments of *Lobophyllia*, and fluid from the cœlentera of large *Fungia* being studied In the former there is a powerful protease, of which the optimum hydrogen ion concentration has been found, an extremely weak lipase, and enzymes capable of digesting—very slowly—starch and glycogen but no other carbohydrate, the temperature of destruction and the optimum hydrogen ion concentration of the former have been determined Apparently the extract has no action on the symbiotic algæ Enzymes in the cœlentera of *Fungia* are confined to protease, apparently the only extracellular enzyme

Most interesting results have been obtained from the experiment on the effect of starvation and feeding on similar corals kept in light and darkness The starved corals receive twice filtered sea water twice daily, while the others receive unfiltered water to which is added every other night the results of a townetting *Fungia*, *Favia*, *Psammocora*, and *Galaxea* have all given good results, and demonstrated that fed corals continue in perfect condition in both light and dark, paling somewhat in the latter owing to the death of the algæ, but starved corals quickly begin to shrink in the tissues, undamaged algæ being extruded in great numbers and the tissues consequently turning pale This happens in both light and dark Newly settled planulæ of *Pocillopora* were placed in light and darkness, in both cases fed and after six weeks those in the light had abundant algæ, especially in the tentacles, while those in the dark, apparently just as healthy, were pure white with transparent tentacles The only conclusion to be drawn from these results, taken in conjunction with the experiments on the feeding and digestive enzymes of corals, is that the algæ are not and cannot be used as food by the corals

Mr A G Nicholls has not yet been able to record a second spawning of the pearl oyster, though several small spat from the November spawning have been found Measurements for growth rate have shown an increase of about 0 5 cm in diameter in 30 per cent of cases His work on calcium has shown that the calcium content of the sea water from the inside station has been remarkably steady, and that there is a noticeable diminution of calcium in water in which corals have been kept for periods of seven and fourteen days Mr G W Otter continues his work, previously outlined, on boring organisms

Mr Spender, who had the assistance of Mr E C Marchant until Jan 9, has been busily engaged on his large scale map of the island, a slow and laborious task Owing to the humidity causing distortion of the drawing paper, he has to plot all points by co ordination He has taken several traverses with the tacheometer between triangulation points, the fringe of the island being almost completely mapped, and hopes to fill in the central detail by plane tabling later He is running level traverses of a precise order across the flat

A preliminary bore with a hand plant has been made in the centre of the sand cay, 13 feet of casing being sent down, and although a level below that of the 'beach rock' was reached, nothing but sand was encountered

The tide gauge has been put up after great labour, entailing the erection, with the assistance of a member of the lighthouse staff, of three 30 foot mangrove poles in the form of a tripod This is giving excellent and most interesting results, and it is now possible to refer any point on the island to mean sea level, while sounding operations are also possible

At the time of writing, the work of the Expedition is being greatly extended by the hiring of a powerful Townsville launch, the *Magneta*, for plankton, hydrographic, and dredging cruises as far north as Cook's passage north of Cooktown

Obituary

COL E LESTER JONES

THE untimely death of Col E Lester Jones, on April 9, meant a loss to the scientific world of a friend and ally whom it will not be easy to replace Col Jones had been for fourteen years the directing head of the United States Coast and Geodetic Survey, and in that capacity had used his talent and energy to promote scientific work and investigation Much of the increased activity and interest in hydrography, geodesy, seismology, and terrestrial magnetism may be traced directly to his influence

Just as it is not possible to gauge the ultimate value of any single scientific discovery, just so is it out of the question to attempt an immediate appraisal of the importance of any one man's life work in the interests of science A hint of the monument Col Jones builded for himself may be found in the splendid organisation the destinies of which he guided for fourteen years The United States Coast and Geodetic Survey, pioneer Government scientific bureau, is to day functioning efficiently, it is well organised, well equipped, and making rapid forward strides For this, the credit must inevitably gravitate toward the man who led, ever encouraged, and efficiently aided its scientific staff

Col Jones was born at East Orange, New Jersey, on April 14, 1876 In addition to extended study abroad, he held an A B degree and an honorary A M degree conferred by Princeton University, and was commissioned a hydrographic and geodetic engineer In 1913 he was appointed deputy commissioner of the Bureau of Fisheries holding that position until being appointed the directing head of the United States Coast and Geodetic Survey by President Wilson in 1915

In addition to his administrative work with this latter bureau, he was the American member of the International Boundary Commission appointed to fix the boundary between the United States, Alaska, and Canada He had also been a member of several important Government and scientific missions One of the last of these was his appointment as a delegate to the twelfth International Geographical Congress held at Cambridge last year

DR CHARLES BEAVIS

THE sudden death of Dr Charles Beavis on April 17 at his residence, Naishcombe House, Wick, Bristol came as a great surprise to those who had recently seen him, apparently in the best of health and full of life and vigour He was born at Hampstead on May 3 1869 and educated at Atherstone Grammar School At the age of seventeen he went to Coblenz then to Bonn, where he read chemistry, physics, and mineralogy under Kekulé, Anschutz, Klinger Bendes, Clausius, and Hertz He afterwards proceeded to Würzburg, working under Emil Fischer, and in 1892 took the degree of Ph D (Magnam Laudem) He returned to London and worked for seven years with Dr Quirin Wirtz, during which time he took his F I C in 1897 In 1899 he went to Wick to start a fine colour department in the Golden Valley Ochre and Oxide Co, becoming manager in 1902, taking over the business in 1904 Although records of published original work are not available since his graduation, Dr Beavis had publicly identified himself with chemistry and the intricate problems of modern colour manufacture, and for many years took keen interest in the Colour Makers' Association of the United Kingdom, of which he was the first and only chairman

---

WE regret to announce the following deaths

Prof John W Harshberger, professor of botany in the University of Pennsylvania and president in 1926 of the American Ecological Society, aged sixty years

Dr F C Madden, C M G, Dean of the Faculty of Medicine, Egyptian University, Cairo, an authority on bilharziosis and schistosomiasis, on April 27, aged fifty six years

Dr August von Schmidt, formerly director of the meteorological geophysical section of the Württemberg State Statistical Bureau at Stuttgart, on Mar 21, aged eighty nine years

Sir George Syme, K B E, president of the College of Surgeons of Australasia and chairman of the Royal Commission on Health, Commonwealth of Australia, aged sixty nine years

Dr Ludwig Wittmack, honorary professor of botany in the University of Berlin and author of the section on the Bromeliaceæ in Engler and Prantl's "Pflanzenfamilien", on Feb 2, aged eighty nine years

News and Views.

The nineteenth May Lecture of the Institute of Metals was delivered on May 7 by Sir Oliver Lodge who chose as his title Some Ideas about Metals A large part of the lecture was devoted to the subject of metallic conduction a theme selected by two of his predecessors by Sir J J Thomson in 1915 and by Prof H A Lorentz in 1925 but by no means exhausted even now Adopting the electron gas hypothesis as to the nature of metallic conduction Sir Oliver Lodge discussed in a fascinating manner the phenomena of thermo electricity and the Hall effect suggesting the lines along which a solution of outstanding difficulties may be pursued Great significance is attached to the results obtained by Kapitza in intense magnetic fields and it is conjectured that a flow along magnetic lines of force indicated by ether theory but too slow to be observed by existing means might be detected if such intense fields could be extended over a considerable region instead of being concentrated in a very small space The earlier part of the lecture however was of wider scope and dealt in a reminiscent vein with some of the anomalies of discovery in physics such as the failure to recognise a new phenomenon through excessive deference to existing views and the happy results sometimes derived from the exercise of boldness in experiment or speculation A wide range is covered by the lecture and the student of the history of physics will find an illuminating survey of some aspects of the growth of the Bohr atom among many thumb nail sketches of the physical discoveries of the present generation from the hand of a master of exposition who has himself been in close contact with such discoveries over the most interesting period in the whole history of the science

Science Service of Washington D C announces that fourteen Americans and five foreigners were honoured at the concluding session of the annual spring meeting of the National Academy of Sciences either by election to membership or to the foreign associateship Prof Arnold Sommerfeld of Munich known for his work on the quantum theory of spectra who attended the scientific sessions of the meeting as a guest, was one of the newly elected foreign associates The others included Richard v Hertwig professor of zoology and comparative anatomy in the University of Munich C de la Vallée Poussin professor of analytical mechanics at the University of Louvain, Willem de Sitter of the Observatory of Leyden, Holland, and Prof F O Bower formerly Regius professor of botany at the University of Glasgow

The new members of the National Academy are Dr Roger Adams, professor of organic chemistry at the University of Illinois Irving W Bailey associate professor of botany, Bussey Institution, Boston, Dr A. F Blakeslee, botanist at the Carnegie Institution s station for experimental evolution at Cold Spring Harbor, N Y, Dr James B Conant, associate professor of chemistry, Harvard University, Dr Bergen Davis, professor of physics at Columbia University, Dr C J Davisson physicist at the Bell Telephone Laboratories New York whose recent work on the wave nature of electrons has proved a most important advance in physics Dr Joel H Hildebrand professor of chemistry at the University of California Berkeley William Hovgaard professor of naval design at the Massachusetts Institute of Technology Dr Albert W Hull research physicist at the General Electric Company s Research Laboratory at Schenectady N Y Frank Leverett geologist of the U S Geological Survey and lecturer in glacial geology at the University of Michigan Ann Arbor Dr Paul W Merrill astronomer at the Mt Wilson Observatory Pasadena California Dr David H Tennent zoologist at Bryn Mawr College Pennsylvania Dr George H Whipple dean of the School of Medicine and Dentistry and professor of pathology at the University of Rochester N Y and Dr Clark Wissler curator of ethnology at the American Museum of Natural History New York and professor of anthropology in the Institute of Psychology at Yale

On Feb 13 last Mr Frederick Chapman palæontologist to the National Museum Melbourne retired from the State service and the National Museum Committee has passed a resolution recording appreciation of the services rendered by him since his appointment on Mar 12 1902 During his twenty seven years of tenure Mr Chapman has arranged and illustrated with his own pen and brush the two extensive galleries of fossils in the Museum identified 22 000 fossil specimens for visitors and registered about 14 000 exhibited specimens He has determined and labelled 7200 specimens in the reference collection of Australian fossils and apart from routine work has described many hundreds of types He is a member of the Australian Research Council and lecturer in palæontology at the University of Melbourne In March last he was elected president of the Royal Society of Victoria At present Mr Chapman is attached to the Commonwealth service as Federal palæontologist directing the examination of bore cores a work with which he is especially acquainted for forty years ago he was helping the late Prof J W Judd of the Royal College of Science to examine the borings from Meux s Well and from Richmond near London whilst only last year he published a work on the Sorrento Bore Mr Chapman s work is familiar through his writings on Foraminifera and on Australasian fossils and the recently published guide book to the Fossil Galleries at the Museum

The Central Electricity Board in accordance with the provisions laid down in the Electricity Supply Act of 1926, has published a report of its work up to January 1929 It will be remembered that the function of the Board is to co operate with the supply industry in Great Britain in reducing production costs to a minimum and concurrently to increase the availability of the supply The method of doing this which has been adopted is to interconnect the more efficient stations by a network of high pressure trans

mission lines, called the grid, and operate 'selected' stations in the most economic way The report indicates that good progress has been made in these directions Many difficulties have been tactfully overcome In central Scotland the Grampian Electricity Supply Company feared that the scheme would be prejudicial to its interests since it had counted on getting much of its revenue by supplying several industrial districts which will be connected with the grid The Board, recognising the importance of developing the water power of the country, has promised to take a load not exceeding a maximum demand of 12,000 kilowatts from the company

THE report goes on to state that in south east England the demand has increased so rapidly that three additional stations had to be selected by the Central Electricity Board The difficulties that were expected to arise owing to the standardisation of the frequency of the supply in central England and North Wales have been carefully considered, and in several cases the Board has given permission for schemes at a lower frequency to be completed, as the savings under the scheme would not have justified the higher expenditure The total value of the work contracted for under the Government scheme up to the end of last year exceeds eight million pounds In Scotland the erection of towers in the Clyde Valley will be completed this month In south east England towers are being built between Bedford and Little Barford, and forty six out of seventy three are now erected One very satisfactory feature is that many land owners have facilitated the work and co operated with the Board in preserving the amenities of the countryside by choosing the most suitable sites for the towers

AT a recent meeting of the Council of the Institution of Professional Civil Servants the announcement of the appointment of a Royal Commission on the Civil Service, with the wide terms of reference indicated by Mr Churchill in the House of Commons, was considered While welcoming such a Royal Commission, the Council is of opinion, however, that such an inquiry can only discharge the task imposed upon it satisfactorily provided that professional and scientific men of standing and administrative experience are appointed to serve on the Commission In its view, the problem of the structure of Civil Service organisation must be approached afresh in relation to the functions which should be accorded to the 'technical expert' in the administrative machinery of the modern State An approach from the traditional Civil Service point of view is considered unlikely to lead to those fundamental changes which are rendered necessary by modern conditions

IN a reprint of certain articles published in the *Journal* of the American Society for Psychical Research during 1928, and now issued under the title of "The Thumbprint and Cross Correspondence Experiments made with the Medium Margery during 1927 and 1928," Dr Mark W Richardson and his associates have collected some of the more striking episodes in the later history of the development of the alleged supernormal phenomena occurring with the Boston medium, Margery (Mrs L R G Crandon) The paper is divided into two sections, one dealing with the thumb impressions upon dental wax which have so far been traced to no living person, and the other to the series of cross correspondences between Margery and other mediums, which have the merit of simplicity, and possess a degree of accuracy which would be regarded with suspicion if it represented any kind of scientific result There is little doubt that, merely considered as a question of mechanical production, the thumb prints are of some interest Unlike the prints which engage the attention of the police, the Margery impressions are made in wax, and are therefore capable of more detailed examination and analysis than are those of two dimensions Moreover, the fact that these wax impressions are said to be negative *and* positive together with 'mirror' images of both these series serves to illustrate the complexity of the problem

THESE wax originals are open to inspection in Boston, and it is clear that an examination of them would be more satisfactory than of the photographs here included, excellent though the latter undoubtedly are Hence any detailed criticism would be out of place, although it ought to be said that in the account there are certain suspicious incidents which again are not absent in the records of the cross correspondences Here we have broadly what is claimed to be the transmission of an idea independently chosen and presented which is reproduced at approximately the same time by two or more mediums at widely separated distances Such a claim lends itself to scientific scrutiny, and it would appear that, under much stricter conditions than those described in this paper, it might be possible to test these phenomena in a manner free from those objections which usually prevent any adequate examination of supposed 'psychic' manifestations

THE Right Hon W Ormsby Gore, Under Secretary of State for the Colonies, recently gave an address before the Royal Scottish Geographical Society on the "Development of our Tropical Dependencies", and the lecture has now been published in the Society's magazine He points out that in the true equatorial territories the combination of high rainfall, perpetually humid atmosphere, and comparatively high temperatures, provides all the circumstances necessary for constant and rank vegetable growth On the north and south, these regions are bounded by great torrid deserts with a rainfall lower, and a temperature far higher, than those found in the true equatorial belt The wealth of the tropics lies mainly in the production of certain foodstuffs and raw materials, which are becoming of increased importance year by year Despite the bountiful and productive nature of the true equatorial regions, there is, however, an extraordinary sparseness of human population A variety of causes retard development, among which the more important are tropical diseases, the ravages of mosquitoes and tsetse flies which attack man and animals, and the prevalence of plant diseases For

the development of the tropics, further research work in tropical medicine and veterinary science is all important In agriculture, also, research is vital since immune varieties of higher yielding strains of particular crops are urgently required Mr Ormsby Gore considers that it is in the fields of economic botany, plant genetics, and soil science that the economic conquest of the tropics has its future In tropical agriculture, medicine, and veterinary science the main problems now to be faced are not so much the cure of diseases as and when they arise but rather the eradication of disease and the maintenance in health of men, animals, and plants

THE first number of *Human Biology*, a new magazine with a definite and specific aim, has made its appearance from the Institute for Biological Research, under the editorship of Prof Raymond Pearl Its object is to publish in readable English original articles in all fields of human biology, including physical and general anthropology, anthropometry, vital statistics, human heredity and eugenics, prehistory, human anatomy, sociology, constitutional pathology, and psychobiology There was need for such a work, for not only has it become increasingly apparent that humanistic researches must all wander into biological fields, but also the publication of papers on human biology found their way into many and scattered journals, and lost the value of a massed attack The first part—the journal is to be a quarterly —contains a varied series of papers, dealing with subjects from human evolution to biological philosophy and medicine All the articles are stimulating in their suggestiveness, but a perusal of some suggests that the editor is to have a hard task to capture the standard of thorough and entertaining readableness at which he aims through his contributors There are no book reviews, but a list of new books and memoirs received at the editorial office is printed as a bibliographical guide There is a niche for *Human Biology*, and this it promises to fill very satisfactorily

DR FRANK B JEWETT, of New York, who has recently been honoured by the American Institute of Electrical Engineers, gave an address on Dec 29 last to the American Association for the Advancement of Science, which has appeared in a recent issue of *Science*, on leadership in industrial research As one of the founders of the Bell Telephone Laboratories, and as one who has been engaged for the last twenty five years in finding and encouraging others to do scientific research in industry, his paper deserves consideration by scientific and technical professors He has worked all his life to promote co operative research, not with any idea of banishing the individual inventor, especially if that inventor happens to be a genius, but in the belief that co operation provides a new method of research In both scientific and industrial research the men who succeed are driven to work by insatiable curiosity about natural laws and not mainly by a desire for personal wealth Looking back over his successes and failures in selecting young men for industrial research during the last twenty five years, Dr Jewett says that the majority of his successes were secured by attaching one third weight to his own personal appraisement and two thirds to that of experienced professors under whom the candidate had worked His failures were mainly due to paying too little attention to the professorial opinion and to attaching too much weight to those whose judgment he should have distrusted In order to promote the peace of mind and the continued productivity of the research worker, it is necessary to encourage him by a sympathetic understanding of the work he has done and the obstacles he has to overcome We are human beings dealing with each other, and no hard and fast rules can be applied to workers in the field of research any more than in any other field of activity

A FURTHER Circular (No 6) has been issued by the secretaries of the International Congress of Forestry Experimental Stations to be held in Stockholm next July, which has been referred to in previous issues of NATURE So far, about a hundred applications to attend the Congress have been received and fifty papers have been presented to be read, the latter chiefly from Europe and the United States It is proposed to set up an organising committee, consisting of one representative from each country, which will deal with questions concerning the organisation of the Congress and the revived International Association of Experimental Stations This Committee will have the power to summon experts to its meetings, which will not clash with the general meetings of the Congress, to assist in the solution of such problems as may arise, small executive sub committees will be appointed when deemed necessary Delegates submitting papers are requested to send in a précis of their papers at once, in order that such summaries may be printed and thus be in the hands of delegates before the meetings at which the papers are read It is further announced that the period of application to attend the Congress has been extended to June 1, although the date of giving notice regarding attendance at the excursions to take place before and after the Congress meetings was left at April 30 The meetings in Stockholm will take place on July 22–27 The first meeting of the organising committee will be held in the afternoon of Sunday, July 21, and this will be followed by a garden party at the beautifully situated College of Forestry at Stockholm, to which all delegates are invited The proceedings of the Congress will open on July 22, and the programme of the first two days' meetings is given in the circular The last meetings of the Congress will be held on Saturday, July 27, when resolutions will be submitted, the election of a president, and the time and place of the next meeting, and the appointment of an executive committee of the Association will be discussed

IN a recent issue of *Science*, Prof Knight Dunlop has a paper on the outlook for psychology, presented before the New York meeting of the American Association for the Advancement of Science He reviews the present situation with special emphasis on what he calls the laboratory method, believing that the laboratory is the centre of true psychological activities It is dis-

appointing that such a subject should be treated so generally, he asserts, but presents no evidence, that the laboratory method has justified itself and contrasts it with the mental test movement and the psycho analytic movement, both of which he looks upon as in a state of eclipse One cannot help feeling either that the position of psychology in the United States is radically different from what it is in Britain, or that Prof Knight Dunlop is comparing the best work of the laboratory with the worst and most uncritical of the practical movements There is no inherent opposition between the laboratory method and scientific method pursued in the field for practical purposes The laboratory worker in psychology as in any other science, can pursue knowledge for the sake of knowledge, regardless of possible practical applications, but he can also receive his stimulus to work from the practical side and pursue his research scientifically with a practical aim The mental tester in his domain and the doctor in his, were confronted with serious problems Neither of them could wait until, if ever, the laboratory worker bestirred himself to help him Because both movements have had over enthusiastic exponents and reckless theorisers, one cannot look upon them as discredited So also has the theory of evolution Perhaps in England less was expected of either mental testing or psycho analysis, and therefore they have been kept in better perspective In the latest edition of Osler and M Crae s Modern Medicine , there occurs the statement "Psycho analysis is of the greatest service for the strictly psychogenic cases and the mental test is used not as a method of universal validity, but as a convenient measure of differentiation

THE effect of the erection of overhead power lines on the beauty of the countryside has been much discussed in the Press Electrical engineers are, however more concerned at present with the possible interference these high voltage lines may produce with telephone lines, radio transmission, and broadcast reception Dr R L Smith Rose has been experimenting, on behalf of the Radio Research Board, at the National Physical Laboratory on this subject and has arrived at definite conclusions These are given in the *Wireless World* for May 8 American experience has shown that if the radio reception station be farther than about half a mile from a high tension overhead line, no interference or disturbing effects will be experienced The station itself may, without causing interference, be supplied with power from the overhead system Experiments were made by Dr Smith Rose to find out the effects of high voltage spark discharges on a sensitive radio receiver in the neighbourhood When a spark or arc discharge initiated by a voltage of about 850,000 and carrying a current of about half an ampere took place, then if the receiver were less than 200 yards from it, disturbance ensued This effect was only serious when long drawn arcs occurred at frequent intervals, a phenomenon which would very rarely happen on transmission lines When the distance was so great as 600 yards, the interference was negligible The distance, therefore, of half a mile which is customarily chosen for other reasons ensures that the disturbing effects produced by man made static' are negligible

TEST transmissions of the new Marconi broadcasting station at Bratislava, Czechoslovakia, have been carried out and satisfactory reception has been reported generally on three valve sets, from all parts of the British Isles The new station comprises a Marconi 12 kilowatt broadcasting transmitter, Type P A 5, employing the principle of low power modulation Its wave length is 277 8 metres (1080 kh), and among its special features is the half wave length aerial, the first of its kind to be used in the broadcast band of wave lengths The station, which is situated about three miles to the east of the town, replaces an old broadcasting station of ½ kilowatt power It is connected by land line with up to date studios in the centre of Bratislava Prague, and Brno

THE Fourth World s Poultry Congress is to be held at the Crystal Palace on July 22-30, 1930 It is being organised by the English Ministry of Agriculture and Fisheries in conjunction with the Scottish Department of Agriculture and the Ministry of Agriculture for Northern Ireland The official host is the Government and Their Majesties the King and Queen and H R H the Prince of Wales have consented to become its patrons National committees have been formed in most countries for the purposes of organising national exhibits, and of selecting papers to be read at the Congress The business activities of the Congress will consist of paper reading sessions national displays of live stock, and commercial exhibits Whilst most that is to be heard and to be seen will deal with the democratisation of information relating to poultry keeping there are to be in addition special paper reading sessions devoted to the presentation and discussion of original scientific contributions in genetics dietetics, pathology, and husbandry This Congress is expected to be no less successful than the last, which was held at Ottawa in 1927, when 3000 delegates and 200 000 members of the general public attended

A FORMIDABLE and very widely spread insect pest of fruits, namely, the Mediterranean fruit fly (*Ceratitis capitata*), has recently, and for the first time secured a footing in the United States We learn from recent *Daily Science News Bulletins*, issued by Science Service, Washington, D C , that its discovery in citrus orchards in Florida, over an area of about 40 square miles, has led to the planning of energetic measures of repression The fly was first found on April 6 and its identity established soon afterwards Specimens were then rushed by air mail to Washington and the identification confirmed It is stated that within one week of the date of discovery, 75 entomologists and plant experts were on the ground, and the battle of extermination has begun !

THE Bakerian Lecture of the Royal Society will be delivered by Prof E A Milne, Rouse Ball professor of mathematics in the University of Oxford, on June 6, the title being "The Structure and Opacity of a Stellar Atmosphere"

At the annual meeting of the members of the Royal Institution, held on May 1, the following officers were elected :—*President*: The Duke of Northumberland; *Treasurer*: Sir Robert Robertson; *Secretary*: Major Charles E. S. Phillips.

The President of the French Republic has, on the recommendation of the Association Technique Maritime et Aéronautique, conferred the Legion of Honour upon Mr. Robert W. Dana, secretary of the Institution of Naval Architects.

The first Pedler Lecture of the Chemical Society will be delivered by Prof. W. H. Perkin, Waynflete professor of chemistry in the University of Oxford, on Thursday, May 30, at 5.30 P.M., the title of his lecture being "The Early History of the Synthesis of Closed Carbon Chains". The lecture will be given in the hall of the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1. Tickets of admission will not be required.

'National Baby Week' is to be celebrated this year in Great Britain on July 1-7. The National Baby Week Council desires that special attention should be directed to three problems: (1) The practical measures that can be taken to combat maternal mortality, morbidity, and disability; (2) what local authorities and parents can do to lessen the incidence and dangers of infectious diseases among young children; and (3) the teaching of parentcraft and hygiene to school children. Particulars may be obtained from the Secretary, Miss Norah March, 117 Piccadilly, W.1.

A publication grant of £2500 is receivable by the Royal Society from H.M. Government during the current year. The grant is available for assisting the publications of other scientific societies, as well as for assisting the separate publication of books, memoirs, etc., of a scientific nature. Applications for grant will be adjudged by the Council of the Royal Society at its meeting early in July, but should be received before the Council meeting of June 13. Applications from societies will be received by the secretaries of the Royal Society; those from individuals must be brought forward by members of Council.

The second meeting of the Internationale Gesellschaft für Sexualforschung will be held in the house of the British Medical Association, Tavistock Square, London, on Aug. 3-9, 1930. It may be assumed that, as was the case in Berlin, the papers presented for discussion will fall into the following groups: biology, physiology, pathology, and therapeutics; psychology, pedagogy, ethics, æsthetics, religion; demography, statistics, social and racial hygiene; sociology, ethnology, and folk lore. All arrangements are in the hands of Prof. F. A. E. Crew, The University, West Mains Road, Edinburgh, to whom all those who are interested are requested to write.

The cheap popular series of books which have long been a feature of publishing enterprise fall into two main divisions; those which have long attained the rank of classics, and those which provide expositions, brief but authoritative, of new problems, or of problems which have assumed new forms or a new importance. Of the latter kind of cheap series, "Benn's Sixpenny Library" is one of the most remarkable (London: Ernest Benn, Ltd.). To mention three examples, rather wide apart as to subject matter, from a number of volumes which have recently reached us—Dr. Cyril Norwood on "The English Educational System", Mr. F. N. Fallaize on "The Origins of Civilisation", and Lord Monkswell on "Railways"—is to convey some idea of the comprehensiveness of the series. Many of the volumes dealing with scientific subjects have been noticed separately in Nature. As at present arranged, the series is to run to some two hundred and fifty books, of which we have already received about a hundred and fifty. The undertaking is one which deserves, and we trust is commanding, success.

A correspondent in Tanganyika has directed attention to an error in the provenance of the wooden dolls described in Nature of Mar. 9, p. 388, where they are attributed to West Africa. This should be East Africa, as the Wamakonde, by whom the dolls were made, are native to Portuguese East Africa.

Applications are invited for the following appointments, on or before the dates mentioned:—A soil analyst in the West of Scotland Agricultural College —The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (May 24). An assistant lecturer in chemistry and an assistant lecturer in biology at the Brighton Technical College —The Secretary, Brighton Technical College, 54 Old Steine, Brighton (May 25). An assistant at the Forest Products Research Laboratory, Princes Risborough, for work on the identification and structure of wood—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (May 25). Temporary assistant chemists at the Government Laboratory—The Government Chemist, Clement's Inn Passage, W.C.2 (May 25). An assistant master to teach mathematics at the Toxteth Junior (Day) Technical School—The Director of Education, 14 Sir Thomas Street, Liverpool (May 25). A part-time demonstrator in chemistry at King's College of Household and Social Science—The Secretary, King's College of Household and Social Science, Campden Hill Road, W.8 (May 29). A demonstrator in the mechanical engineering branch of the Military College of Science, Woolwich—The Assistant Commandant, Military College of Science, Woolwich, S.E.18 (May 31). A pathologist and curator at the Royal London Ophthalmic Hospital—The Secretary, Royal London Ophthalmic Hospital, City Road, E.C.1 (May 31). An assistant lecturer in physical chemistry in the University of Sheffield—The Registrar, The University, Sheffield (June 3). A demonstrator in the department of physiology of Middlesex Hospital Medical School—The School Secretary, Middlesex Hospital Medical School, London, W.1 (June 5). A professor of mechanical engineering at the College of Engineering, Guindy, Madras—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S.W.1 (June 8). A research chemist in the department of Coal Gas

and Fuel Industries of the University of Leeds—The Registrar, The University, Leeds (June 9) A lecturer in civil engineering in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W C 2 (June 11) Two research fellows in the Department of Chemical Technology of the Imperial College of Science and Technology for work in connexion with the carbonisation of coal, gaseous combustion or catalytic reactions—The Registrar, Imperial College of Science and Technology, South Kensington, S W 7 (June 15) Three assistants in the Research Department, Woolwich, under the Directorate of Explosives Research—The Chief Superintendent, Research Department, Woolwich, S E 18 An examiner in the Aeronautical Inspection Department, Air Ministry, Kidbrooke, S E—The Secretary (I G), Air Ministry, W C 2 A temporary woman lecturer in geography at the Warrington Training College, temporarily at St John's College, Battersea—The Principal An assistant in the Public Health Laboratories and Bacteriological Department of the University of Durham College of Medicine—The Registrar, University of Durham College of Medicine, Newcastle upon Tyne

Our Astronomical Column

The Total Solar Eclipse of May 9—Unfortunately, the news from the official British parties at Alor Star and Patani are very disappointing At the latter station nothing could be done owing to thick clouds At the former the clouds were thinner, and some plates were exposed, but it is feared that they will be of little value

Fortunately, the parties in Sumatra and the Philippines had better conditions Iloilo (Philippines) was occupied by American and German parties from the Naval Observatory Washington, and from Hamburg There were also two English observers, Dr R L Waterfield and Mr W Lloyd There was a little high cirrus cloud here, but it does not appear to have interfered much with the observations, there was a fine flag shaped prominence, which the Americans humorously compared to the Stars and Stripes The corona was of maximum type and had six pointed streamers, Dr Waterfield reports that it was brighter and more extensive than that of June 1927, but the darkness during totality was not so great He states (*Daily News* May 11) that the infra red plates overcome thin clouds and give the corona a harder outline, but no greater extension, than ordinary plates A kinematograph film was exposed during totality by the Washington party, but this had not then been developed

Some of the parties in Sumatra report some interference by cloud while others enjoyed very good conditions Prof J A Miller, of Swarthmore Observatory, who probably holds the record for the number of eclipses he has observed, took coronal photographs with a camera of 65 feet focus, comparison of his plates with those taken in Iloilo will reveal any coronal changes that may have taken place in an hour Prof E F Freundlich, from Potsdam, has telegraphed that he obtained successful results He was studying the Einstein bending of light, a problem on which he was engaged even in pre War days, before the publication of the general theory of relativity This is the third totality that has been successfully observed in Sumatra in the present century, the others were 1901 and 1926

Since the above was written, a Reuter telegram received from Dr Jackson at Alor Star reports as follows Developed plates better than anticipated Transparencies equal to that of Giggleswick Several beautiful prominences, one 150,000 miles long, 100,000 miles high, with coronal arches Apparatus for velocity in the corona satisfactory

The Pleiades—At the meeting of the Royal Astronomical Society of May 10, the George Darwin Lecture was delivered by Prof Ejnar Hertzsprung, of Leyden Observatory He chose as his subject the Pleiades, and began with describing the methods by which the stars of the cluster could be discriminated from background stars by photographic determinations of their proper motions Slides were shown of the proper motions of each magnitude of stars from the third to the fifteenth The brighter ones are all cluster stars, it is only in the case of the faintest stars that any doubt arises as to which belong to the cluster, and even here there are only one or two doubtful cases

Prof Hertzsprung then proceeded to divide the stars into the spectral classes, which was done for the fainter stars by their colour indices There are no red or yellow giants the brightest stars being of type *B*, and the faintest being red dwarfs Prof A S Eddington remarked after the lecture that the resulting diagram of spectral type and absolute magnitude brought out the 'main sequence' more vividly than he had seen before, since it was the first time that such a large number of stars, all known to be at the same distance, had been studied The globular clusters are too remote for the dwarf stars in them to be seen The colour indices of the non cluster stars in the region were also determined, there was some reason to think that they were rather redder than the average, which might possibly be caused by the presence of the nebulosities round the principal stars

Prof Hertzsprung adopted the parallax of the cluster as 0 0065", which is smaller than some other estimates, which go up to 0 01" He ascribed the proper motion almost entirely to the motion of the solar system

Measuring the Heat of the Stars—The May *Scientific American* contains an account by Prof H N Russell of the very delicate measures of stellar heat made by Messrs E Pettit and S B Nicholson with the 100 inch reflector at Mount Wilson The wires of the thermocouple are about one thousandth of an inch in diameter and weigh 1/600 of a grain Betelgeuse is the star that gives us the most heat, but even this only raises the temperature of the wire on which it falls by 1/60 of a degree, and produces a current of one seven millionth of an ampere This, however, suffices to move the spot of light reflected from the mirror of the galvanometer through 18 inches Some stars invisible to the naked eye give a measurable displacement The next in order after Betelgeuse are Antares, Sirius, Canopus, Gamma Crucis, Arcturus, Alpha Herculis, Aldebaran, Mira at its maximum It is noted that a very red star, such as Alpha Herculis, sends us 50 times as much heat as a white star of the same visual magnitude, in spite of the fact that the surface temperature of the first is only 2300°, that of the second being 6000° The article contains a picture of the thermocouple used by Dr W W Coblentz for measuring the heat received from the planets

Research Items

The Religion of Mentawei.—Mentawei Islands, lying west of Sumatra, owing to political conditions, have received more attention from Dutch and German than from English speaking ethnologists. They were, however, visited in 1926 by Mr. Edwin M. Loeb, as a research scholar of the University of California, and he has now published an account of the religious organisation of the Pageh group of islands in the *Publications in American Archæology and Ethnology*, vol. 25, No. 2 of that University. He deals more especially with the *punen* system. The *punen* is the community religious festival (as distinct from the *lia* or family festival) which is attended by all members of the *uma*, the communal house. The festival is of long duration, sometimes lasting for years. It takes place at the building of a new communal house, the choice of a new priest, the making of a new field, the spilling of blood in the village, an epidemic, and so forth. The main ceremonial acts are the slaughter of pigs and chickens, the sacrifice of their livers and haruspication. The souls of the dead members of the *uma* are invoked to return, and imitative dances are held, and towards the end of the festival monkeys, deer, and sea turtle are hunted. All men sleep in the *uma* and sexual intercourse is taboo. The religious beliefs of the Mentawei Islands are animistic. They believe in nature spirits, souls, and ghosts; but the nature spirits, with a few exceptions, are not given names. They are the spirits in the sea, the jungle, and so forth. The exceptions are a god who causes earthquakes, the original meaning of his name being 'grandfather'. It is on account of this god that a human sacrifice used to be offered at the building of the *uma*. Other specially designated gods are two water spirits, the first being propitious if due sacrifices are offered and no ritual sin has been committed, and the second is evil. The soul cult is specially directed to the preservation of health and long life, while ghosts are the bringers of disease to whom prayer is offered for purposes of witchcraft, and to whom sacrifice is made only when they have entered a village bringing sickness, to induce them to go away.

The Regent's Park Medusa.—Prof. C. L. Boulenger and W. U. Flower (*Proc. Zool. Soc.* Part 4, 1928) record observations on the freshwater medusa, *Craspedacusta* (*Limnocodium*) *sowerbyi*, which reappeared in the *Victoria regia* tank in the Royal Botanic Society's Garden in Regent's Park in 1928 (see also Nature, July 14, 1928, p. 58). The youngest specimens—about half a mm. in diameter—agree in structure with the description of American examples of the medusa of *Microhydra ryderi*. The latter is therefore merely the young stage of *C. sowerbyi*. The description given of *Microhydra germanica* shows that it corresponds with the young forms of *C. sowerbyi*, and the Chinese species *Limnocodium kawaii* is also a synonym. The Japanese *C. iseanum* is clearly differentiated by the structure of its sense organs. The living *C. sowerbyi* passively sinks in the water, the velum hanging downwards from the umbrella margin and the tentacles floating upwards, the lip of the oral opening of the elongate manubrium being widely extended so as to catch organisms. In addition to this 'tow net' method of feeding the medusa can feed on bottom living forms, for the stomach has been recorded filled with *Arcella*. The authors consider that the increase in size of the mouth and the large manubrium of *Limnocnida* show that this genus has become more perfectly adapted to the tow net method of feeding, but the radial canals are shortened and the sex cells remain in the manubrial ectoderm, that is, in the primitive position in which they first appear in the young *Craspedacusta*.

The Muskrat in Europe.—In 1905 the American muskrat (*Fiber zibethicus*) was introduced into Bohemia on an estate near Prague, where it was hoped that it would breed and help to supply the demand for musquash fur which was then in fashion. The experiment succeeded better (or worse) than was expected, for the colony burst out of control and soon mid Bohemia was overrun. About 1914, Bavaria and Saxony were invaded, in 1924 Silesia, and in 1928 the outposts were still spreading (Hj. Broch in *Naturen*, January 1929). The extent of the conquest may be judged by the fact that in 1921, 60,000 to 80,000 muskrat skins were sold in Berlin at prices which compared favourably with those obtained for American skins. Such an invasion could not but have its ill effects. The muskrats, largely vegetarians, have attacked corn, potatoes, kohlrabi, turnips, and carrots. They have extended their carnivorous diet to frogs and fish, and the damage caused by their burrows to road and railway works has not been negligible. Strenuous measures have been adopted against the pest in the affected countries; in Bavaria special muskrat catchers have been appointed. The whole story is but another illustration of the danger of introducing animals in casual and unconsidered ways to new countries, and it strongly supports Dr. Broch's plea that there should be no relaxing of the law forbidding the importation of live muskrats into Norway.

Animal Hypnosis.—J. ten Cate (*Biol. Zentralbl.*, Bd. 48, Heft 11) discusses the problem of animal hypnosis. Czermak (1856) found he could produce complete immobility in the newt by suddenly seizing with forceps a leg or the tail. Similar immobility after a sudden strong stimulus is met with in other animals, especially in insects, and is known even in a few mammals. But there are other cases in which the hypnotic condition is brought about by much weaker stimuli lasting for a longer period, for example, in consequence of holding the animal, by the suppression of the reactions of flight, defence and turning over, by transient pressure on definite parts of the body, by continuous gentle contact, etc. Hypnosis in these cases appears only under quite definite conditions and its origin is by no means so simple as has been assumed. The author describes experiments with the skate, the cockroach, the salamander, the rabbit, and the octopus, in which hypnosis was produced by the action of definite stimuli. He proceeds to refer to the condition of the musculature and to discuss the origin of hypnosis in animals. He concludes that in the vertebrate series the significance of the cerebrum for the realisation of the condition of hypnosis becomes the more important according to the higher grade of development of the central nervous system. Among the invertebrates the general rule appears to be that the higher the animal the more significant are its cerebral ganglia in regard to the origin of hypnosis.

Chromosomes of Maize.—A useful study of chromosome numbers in many different varieties of maize has been made by Randolph (*Memoir* 117, Cornell Univ. Agric. Expt. Station), who used the iron aceto carmine method. All the different types of maize, including dent, flint, pop, and sugary, were examined,

including both meiotic and somatic chromosomes, and the chromosome counts in 338 plants were determined In accordance with previous work, the typical diploid number was found to be 20 in all varieties But plants with a higher number were found in two sugary and two starchy varieties, and in certain other cultures In the exceptional cultures the numbers ranged from 21 to 28, but were constant in each individual, with rare exceptions The chromosomes vary in length from about 2 microns to 4 5 microns, and the extra chromosomes were of the smaller size Segmentation, fusion, duplication through non disjunction, and hybridisation are discussed as methods by which the additional chromosomes may have arisen, but further studies are necessary before the exact method can be determined

SOFT WOOD IMPORTS INTO NEW ENGLAND —Much has been read of the threatened famine in soft wood coniferous timber supplies, and the matter is admittedly one deserving the closest attention The intricacies of the question are very considerable, both in the Old and the New Worlds A point bearing on this matter was discussed by Mr Franklin W Reed, of the National Lumber Manufacturers' Association, at the recent New England Forestry Conference (*Daily Science News Bulletin*, Science Service, Washington, D C) Mr Reed stated that shipping lumber to New England, traditionally a forested region, seems like carrying coals to Newcastle , yet lumber is being shipped into the State and no tariff wall can keep out the invading lumber, for it is American lumber from the Pacific north west It comes into the New England market, partly because the digging of the Panama Canal has made intercoastal freight rates cheap, and partly because the Pacific lumbermen have been caught in an economic trap of overproduction and have to dispose of their product at abnormally low prices in order to maintain their establishments "The present unfavourable condition, from the point of view of the New England producer, will end", said Mr Reed, "when the excessive exploitation of the virgin stands of the Pacific coast is ended, either through agreement among the lumbermen or through exhaustion of the more easily accessible timber" Although New England may look with equanimity to such exhaustion, it would prove a serious matter for wider United States and world markets In the meantime, however, New England timber owners and lumberers are advised to consider the possibility of exporting hardwood products to the Pacific States via the Panama Canal This section, it is pointed out, though possessing a surplus of soft woods, has almost no hardwood resources and is now importing oak from Japan It appears possible, therefore, that an exchange of New England birch, beech, and maple for Pacific Coast soft woods might prove an economic possibility

WATER COOLED MERCURY VAPOUR LAMPS —The Lummer and Straubel mercury vapour lamp, which furnishes a very bright light source of small extent and proves most useful in spectroscopic work and as a subsidiary to devices for obtaining monochromatic light, has the disadvantage that it requires to be cooled in a current of water In the *Rendiconti* of the Royal Lombardy Scientific and Literary Institute for 1928, Dr Luigi Piatti, of the University of Pavia, describes a simple arrangement, which both prevents the lamp from coming into action unless the water is flowing and extinguishes it automatically if the water supply fails Moreover, the arrangement is such that the electric circuit in which the lamp is inserted is kept well insulated from the cooling water

FUNDAMENTAL CONSTANTS —Prof A S Eddington's theory of the relation between certain of the fundamental constants, to which several references have been made in NATURE this year, lends particular interest to two new numbers which have been published recently H Feder, working in the late Prof Wagner's laboratory at Würzburg, who has remeasured Planck's constant h by a method based on the excitation of the continuous X ray spectrum, now finds for it a value of $6\ 547 \pm 0\ 003 \times 10^{-27}$ erg sec H D Babcock, of the Mount Wilson Observatory, has revised a previous estimate of the specific charge of the electron (e/m) which he had made from the magnitude of the Zeeman effect for a number of spectral lines of known spectral types, and gives as its value $1\ 7606 \pm 0\ 0012 \times 10^7$ e m u /gm In each case the changes called for in the older standard values are less than one part in a thousand, although it has to be remembered that the former method presupposes a knowledge of the actual charge on an electron (e), and the latter a knowledge of the velocity of light The accounts of the two investigations are published in the *Annalen der Physik* (vol 1 No 4), and in the January issue of the *Astrophysical Journal* respectively

QUANTUM MECHANICS —Dr P A M Dirac has reviewed some of the more recent developments of quantum theory very lucidly in the introductory paragraphs of a paper in the issue of the *Proceedings of the Royal Society* for April 6, on the properties of many electron systems Quantum mechanics is defined as "the general theory of all quantities that do not satisfy the commutative law of multiplication" Dr Dirac considers that the general theory is now almost complete, apart from the question of the exact form in which relativity considerations have to be introduced The latter, however, are only of importance where high speed particles are concerned, and so the underlying physical laws necessary for the mathematical formulation of a large part of physics and the whole of chemistry may be regarded as completely known the difficulty is only that insoluble equations are frequently encountered in the applications of these laws to specific systems Dr Dirac has given a sketch of the history of the spinning electron which brings out clearly the nature of the problem presented by the interaction of the orbital electrons of atoms and of molecules, and the way in which the impasse which this presented was removed by recognition of the fact that the electrons are actually indistinguishable one from another, and so can change places without our knowledge This 'exchange' type of interaction leads also to satisfactory theories of homopolar valency and of ferromagnetism Dr Dirac's main object in this paper has been to take the ideas and results of group theory, which has been used extensively by German theoretical physicists, and to translate them into the more general and apparently simpler language of quantum mechanics, a transformation which appears to have the additional advantage that it often enables a simple physical meaning to be attached to an otherwise abstract theorem

GRID CONTROL IN ARCS —I Langmuir and A W Hull have contributed a paper to the March number of the *Proceedings of the National Academy of Sciences* of the United States, from which it would appear that considerable developments in the use of enclosed arcs may be expected in the near future The principle underlying the construction of the new tubes is the combination of grid control of the current from a hot cathode with conduction through an ionised gas, with the essential reservation that a

circuit can be made by raising the potential of the grid, but cannot be broken by again lowering it, a negative grid in a strongly ionised medium simply attracts to itself a thin sheath of positive ions, which act as a perfect electrostatic shield to the main body of the discharge To stop a current flowing, the anode potential must be reduced to the neighbourhood of the ionising potential of the gas, and hence the grid does not affect the instantaneous value of the anode current, but only its average value The action of the grid, once a discharge has been started, is in fact the same as that of the small exploring electrodes that are now used in the investigation of many types of gaseous discharges More details of the arc tubes are being given by Dr Hull in a series of articles in the *General Electric Review* Perhaps the most remarkable feature of the first of these—in the April number—is the shape which is now being given to the electron emitting surfaces of the cathodes The bare filament type has been almost abandoned, and there has been substituted an elaborate structure of appropriately coated ribbons or vanes, in the design of which special care is taken to ensure that the emitting surface is efficiently insulated thermally These tubes have already been made in metal, as well as in glass

BREEZE AND CLINKER AGGREGATES —Concretes made from furnace residues as aggregates often develop cracks within a short time of setting, and the causes of such failures have been investigated at the Building Research Station The experimental methods employed and the results obtained are described in detail in *Technical Paper, No 7*, by F M Lea (London H M Stationery Office) Many breezes and clinkers contain combustible matter and even unburnt coal, and it is this material that is, in general, responsible for failure The absorption of moisture and the oxidation of the coal cause swelling movements which may continue over a period of some days, and are particularly noticeable during the setting period and early life of the concrete The presence of more than 40 per cent of combustible material in the breeze invariably results in a low grade concrete, and the properties of the concrete improve as the combustible content decreases Failure due to the presence of sulphur or its compounds appears to be rare, and up to 0 4 per cent of sulphur as sulphate and 0 75 per cent in other forms, is permissible Other impurities do not appear to cause failure

A METHOD OF PRODUCING SOUND STEEL INGOTS — In a paper read before the Iron and Steel Institute on May 3, Sir Charles Parsons and H M Duncan described an experiment carried out on a large scale to produce steel ingots of exceptional soundness The mould used consists of a strong steel casing lined with specially shaped firebricks and is closed by a cover similarly constructed and a bottom chill of steel or cast iron of large dimensions Through the cover are openings for the pouring of the steel, the escape of gases, and for the insertion of oil burners to keep the surface of the steel hot In this way the metal is constrained to solidify from the bottom upwards, and not, as in the ordinary ingot, from the sides inwards The ingots produced, weighing as much as 20¼ tons, are, as would be expected, very free from axial unsoundness and fairly free from segregation The height of the ingot is small compared with its diameter For purposes of handling in forging, a stalk must be cast on to the ingot after it has just set. The mechanical tests given by such an ingot are distinctly better than those from a normal ingot of similar weight, particularly as regards specimens cut transversely In the typical ingot discussed, with a height of 45 in and a diameter of 70 in, the typical V segregates of the normal ingot are absent, or shown only in a series of basin shaped white markings on the sulphur print In this ingot the oil burners had been concentrated on the centre of the top surface, but since then better results have been obtained by arranging the burners around the sides of the mould

AREA COMPUTING SCALE —A useful device for computing the approximate area of plane figures of irregular shape is issued by Messrs G Cussons Ltd, Technical Works, Manchester It consists of a celluloid rectangle with graduated radial markings designed to give the required area in square inches to two decimal places As a substitute for Simpson's and other computing rules it should prove very serviceable in certain circumstances, since it needs only to be laid on the paper Special scale markings have been included to ensure full accuracy in limiting cases where this might otherwise be lost The instrument is stoutly made but transparent, whilst the markings are distinct and the figures clearly legible Explicit instructions for use, and easily grasped are given in a circular accompanying the area computing scale, and a number of illustrations are included The theory of the instrument has been given by Mr R W K Edwards in the *Proceedings of the Royal Society* vol 73, and elsewhere

EFFECT OF NITROGEN PEROXIDE ON COMBUSTION —In vol 73 of the *Proceedings of the Manchester Literary and Philosophical Society* (1928–29), Prof H B Dixon and W F Higgins record further observations of the ignition temperatures of gases determined by their 'concentric tube' method whereby the influence of surfaces is practically eliminated The abnormal behaviour of ether vapour was confirmed, and a discovery of interest was the remarkable accelerative effect of small quantities of nitrogen peroxide on combustion, as shown by a considerable depression of the ignition temperatures of ether and hydrogen in air One part of nitrogen peroxide in 12,000 of air caused a depression of 30° in the value for ether in air, 1 part of nitrogen peroxide in 200 of air brought the ignition temperature of hydrogen down to 455° These observations may be correlated with the recent observation of H W Thompson and C N Hinshelwood that nitrogen peroxide in suitable small proportions accelerate the union of hydrogen and oxygen at temperatures just below ignition They emphasise also the rôle of peroxides in accelerating combustion reactions of several types

ILLUMINATION IN BUILDINGS —Article No 18 of volume 19 of the *Scientific Proceedings of the Royal Dublin Society* deals with the measurements of the ratios of the illumination at various points within buildings to the illumination from the sky at points outside, made by Drs W R G Atkins and H H Poole The measurements were made by means of photoelectric cells and galvanometer deflections, so that they involve no visual comparisons of brightness They are expressed in terms of the 'daylight factor,' that is, the ratio of the illumination of a small horizontal surface inside a room and outside where it receives light from the whole sky, but no direct sunlight The daylight factor in a well lighted dwelling room is about 1 per cent, and close to a window may be 7 per cent In an ancient church it sank to 0·2 as the mean value for about thirty different points, at some of which it was only 0 03 The authors point out that with such low factors it is not worth while to fit glass transparent to ultra violet light in windows which do not receive direct sunlight

Permian Diptera from Warner's Bay, N S.W

By Dr R J TILLYARD, F R S

OF the myriads of species of insects which swarm upon this earth, none is of such absorbing interest to mankind in general as the two winged flies grouped together in the great order Diptera This order is, by common consent, admitted to be one of the most highly specialised within the class, if not actually *the* most highly specialised of all Yet, while no un doubted fossils of the order Lepidoptera, for example, are known older than the early Tertiary, definite, though somewhat obscure, dipterous types are known from the European Lias We know, however, that the Lepidoptera must have existed for millions of years as obscure and very small types similar to *Micropteryx* and its allies, and that these in their turn had a common origin with the Caddis flies or order Trichoptera Ancient representatives of this latter order also occur so far back as the Lias, and I have previously given reasons why the common stem of the two orders Lepidoptera and Trichoptera must be regarded as having arisen from an extinct side branch of the older order of Scorpion flies or Mecoptera, which goes back, geologically, almost unchanged to the Lower Permian and probably also to the Upper Carboniferous

More recent researches into the origin of the Diptera indicate clearly two outstanding facts, (*a*) that they are, of all existing orders, the most closely allied to the Mecoptera, and (*b*) that they must have had origin from the Mecoptera by way of a type, or types, closely resembling the hypothetical common ancestor of the Lepidoptera and Trichoptera, but retaining the markedly mecopterous character of an unbranched first cubitus in the forewing, whereas this vein is always branched in the other two orders A number of forms clearly belonging to this ancestral group, which I have elsewhere called the order Paratrichop tera, but which Dr Crampton prefers to call Proto diptera, were described by me from the Upper Trias of Ipswich, Queensland (*Proc Linn Soc N S W*, p 199, 1919) Later on, through the discovery of the older insect fauna of Belmont, N S W, of Upper Permian age, these forms were linked directly with the true Mecoptera by way of the two fossil genera *Belmontia* and *Parabelmontia*, which I placed in the new order Paramecoptera (*Proc Linn Soc N S W*, p 234, 1919, and p 286, 1922)

Fossil hunting at Belmont has always been a very arduous task, because of the hardness of the rock and the extreme rarity of the fossils A good average would be about one wing for three days' hard labour! Under such conditions it never seemed likely that a full knowledge of the Upper Permian insect fauna could be obtained The late Mr John Mitchell, who discovered these beds, had always in mind the possi bility of finding an extension of them somewhere around the shores of Lake Macquarie With the aid of Mr T H Pincombe, he succeeded in exploring a number of localities with the same geological horizon, and finally they opened up the rich fauna of Warner's Bay, on the shores of the lake above mentioned

The Upper Permian of Warner's Bay has now yielded several hundred specimens, most of which still await description Apart from abundant Homoptera and two problematical remains of Odonata, the fauna is *entirely holometabolous*, consisting of the dominant order Mecoptera and the orders Paramecoptera, Neuroptera Planipennia, Protocoleoptera, and Coleop tera The extensive representation of the order Mecoptera has brought to light so many new types that it is now found advisable to include the orders Paramecoptera and Paratrichoptera as suborders of that order, by means of a very slight extension of its accepted definition *With this extension accepted*, it would be scientifically correct to state that the three orders Diptera, Trichoptera, and Lepidoptera *have been evolved from mecopterous ancestors*

The most interesting fact about the Warner's Bay Beds, as contrasted with the neighbouring Belmont Beds of the same age, is the abundance of very small insects This is particularly noticeable in the Homop tera and Mecoptera In the latter order there are large numbers of tiny, fly like Mecoptera, closely allied to the existing Australian family Nannochoristidæ Some of these are practically complete specimens, and the more slender of them appear to have had hind wings in various stages of reduction, though their habit of dying with all four wings closely folded together makes the working out of the hindwing a very difficult task

Bearing in mind the fact that four winged Para trichoptera are known to have lived in Australia right up to Upper Triassic times, while the oldest known true Diptera are Liassic, it did not seem very probable

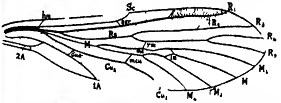

FIG 1—*Permotipula patricia* n g et sp. Forewing Length 5 mm Upper Permian of Warner's Bay, N S W Discovered by Rev A J Barrett, 1928.

that we should ever discover true Diptera at Warner's Bay But I have had the possibility in mind for some years, remembering that Protocoleoptera are found alongside true Coleoptera in the same beds, and Protodonata alongside true Odonata in the Lower Permian of Kansas Every small Mecopteron has been carefully studied in the hope of finding something more definitely dipterous than any hitherto known But, until quite recently, the search was unavailing

When I returned to Australia in October last, my friend the Rev A J Barrett, who had become interested in the Warner's Bay Beds, sent me a small parcel of fossil insects which he had found there. Looking through these, I found the distal two thirds of a small wing which seemed to me so obviously dipterous that I at once proceeded to study it in detail To my great joy I found that both obverse and reverse impressions had been saved, and that in one of these the basal portion of the wing was covered by a small piece of rock It is a risky matter to attempt to uncover hidden portions of fossils in this cherty shale; but I took the risk. A lucky stroke removed the overlying piece, and succeeded in expos ing the complete wing, with only minor damage To my astonishment, not only was this found to be truly dipterous, with an unexpectedly petiolate basal por tion, but it must also be definitely classified as Tipuloid, and distinctly more advanced than such living forms as the Tanyderidæ, which have retained the original four-branched radial sector (*Rs*)

Fig 1 shows this remarkable wing, which is just 5 mm. in length. The missing portions of the costa, apex, and posterior margin, and of the apical part of the first cubitus, are indicated by broken lines;

otherwise the wing is complete The wing is of the greatest interest, because any student of venation would certainly classify it as dipterous and nothing else, and yet *we do not know whether the insect to which it belonged had four wings or only two!* Also, it is the oldest known dipterous type of wing by many millions of years

To facilitate discussion, it would be advisable to name the wing at once At Mr Barrett's request, I name it after my wife, as *Permotipula patricia* n g et sp The wing must be classified in the superfamily Tipuloidea, in a new family Permotipulidæ characterised by the slight degree of petiolation, the short $2A$ and the elongate median cell (mc), and in a new genus *Permotipula* distinguished by the form of Sc, the positions of rm and mcu, the extreme narrowness and irregularity of mc, and the sessile origin of both median forks from that cell A full analysis of the venational characters and a comparison with known archaic forms of Diptera will be published elsewhere The figure itself is sufficient diagnosis of the species

This discovery appears to indicate that the tendency towards lengthening and narrowing of the wings, which is marked enough to have been commemorated in the very name of the ancestral order, Mecoptera, ran to two successful specialisations The first of these, the family Bittacidæ, retained all four wings, and so remains classified to day as a family within the Mecoptera The second evolutionary effort, acting on much smaller and more insignificant types allied to the Nannochoristidæ, produced the true Tipuloid Diptera, or two winged analogues of the Bittacidæ From such small and obscure forms as the one now discovered, the great order Diptera must have originated, with all its multitude of new types, just as the even greater order Lepidoptera must also have originated from small and obscure types resembling *Micropteryx* and its allies For a correct understanding of the larval forms of these two great orders, maggot and caterpillar alike, we must go back to the ancient polypod larva of the true Scorpion flies

The Department of Scientific and Industrial Research

A PERUSAL of the Report of the Department of Scientific and Industrial Research for the year 1927–28 (Cmd 3258 London H M S O), which includes a summary review of the work carried out under the various research organisations of the Department during the year, will provide the reader with abundant evidence of the wide range of the activities and responsibilities of the Department The position of the research associations formed under the ægis of the Department is discussed elsewhere in this issue (p 749) The National Physical Laboratory and the Geological Survey have been for some years under the general direction and control of the Department, and there are between forty and fifty research boards and committees, dealing with such diverse subjects as chemistry, fabrics, engineering, metallurgy, physics, radiology, building, architectural acoustics, heating and ventilation, food, forest products, fuel, atmospheric pollution, national coal resources, water pollution, adhesives, dental investigations, gas cylinders, illumination, lubrication, and X rays To attempt to give, in a reasonable allowance of space, a condensed compendium of what the report has to say on all, or even most, of these activities, is obviously impossible, and we must be content to select, more or less at random, some features of interest

There are 36 pages devoted to a summary of the main features of the work of the nineteen research associations still in receipt of grant aid from the Department The Wool Research Association has introduced this year a new woollen ring spinning frame which, it is claimed, is capable of producing two and a half times as much yarn per spindle as the standard frame, and of giving a superior yarn It is the outcome of an exhaustive analysis by the latest scientific methods of the exact functions of every part of the existing 'Standard' machine, an analysis which showed clearly the directions in which simplicity could be effected without destroying practical efficiency Reference is made to the new lead alloy introduced by the Non Ferrous Metals Research Association as a result of investigations undertaken in co-operation with the Research Department, Woolwich It has a strength, weight for weight, some 40 per cent greater than the ordinary commercial lead which is used for lead pipe, and, because of its freedom from the defect of a peculiar type of cracking, it is being used as a covering for electric cables. The remarkable, but not surprising, statement is made that "the Association has hitherto failed, in spite of many efforts, to arouse any interest in it among manufacturers of lead pipe and sheet' This is but another instance of the many that could be given to illustrate the lag between the completion of a research and the application of its results to large scale industrial practice

The report directs attention to the surprising statement in the inaugural address of the president of the Institution of Locomotive Engineers, in September 1927, that locomotive engineers have "not at their disposal any facilities for trying out experimental scientific research", and that there is no existing organisation in Great Britain which is available generally for the accurate testing of the performance and thermal efficiency of a locomotive The Advisory Council, as the result of recent conferences on this subject, foreshadows the establishment of a national organisation for locomotive research

On the subject of low temperature carbonisation the report states that "several processes are now being operated on a scale large enough to provide reliable data by which the possible limits of commercial success can be judged" A subsidiary company of the Gas Light and Coke Company, for example, is erecting plant to try out on a commercial scale the experimental retorts developed at the Fuel Research Station Other investigations, connected with fuel research, to which brief reference is made, are those on metallurgical coke, which are being carried out by the Federation of Iron and Steel Manufacturers in co operation with the Department, on the use of pulverised fuel in the mercantile marine, and on the economical use of coal

The Empire Marketing Board has provided a sum of £18,500 for the period up to Mar 31, 1929, which has enabled the Director of Food Investigation to initiate a new programme of research on the preservation and transport of fish Attention has been paid, in the first place, to those investigations likely to yield results capable of adoption by the existing fishing fleets, and, in particular, to an investigation into the possibility of landing in first rate condition an increased proportion of the fish caught "Preliminary investigations carried out during the summer of 1927 showed, rather unexpectedly, that the flesh of fish is not inherently of a highly perishable nature, but that, on the other hand, the natural rate of deterioration is profoundly affected by secondary environmental factors" Aberdeen has been selected

as the location of a research station for the fundamental researches needed

In summarising the work done and being done on cement and concrete research, attention is directed to the fact that there are two main differences between concrete and steel which are in themselves sufficient to account for the many anomalies observed by engineers when applying to concrete the standard methods of test to determine the strength of steel The first of these differences is the normal expansion and contraction of the material as the moisture in the surrounding atmosphere varies and the second is the gradual flow of concrete under load Investigations on the measurement of adhesion stresses and of stresses introduced in the steel of reinforced concrete by the shrinkage of cement have been undertaken at the Building Research Station and have already been productive of data of much importance

Coming to the Department's activities that relate to what is usually called pure science we may note that the grants for researches research workers and students for the year ended Mar 31 1928 amounted to £31 346 net The grants made under this head during 1927 28 were in number 186 and the grants refused 118 as compared with 214 and 213 respectively for the previous year The researches so assisted in the year under review include among others the work carried out by Sir William Bragg and his collaborators on the X ray examination of materials and investigations on magnetic phenomena by Dr P Kapitza and his collaborators

Age-Hardening of some Aluminium Alloys

SOME physical properties of five typical aluminium alloys containing copper magnesium silicide or both have been examined by Dr M I V Gayler and G D Preston and the results were presented at the March meeting of the Institute of Metals From this experimental work the following conclusions regarding the causes of the age hardening of such materials are reached

On prolonged annealing it is known that the precipitation of $CuAl_2$ or Mg_2Si, or both depending on the composition of the alloy occurs The changes of density which occur during ageing together with the accompanying changes in the lattice parameter suggest that a similar precipitation from the solid solution takes place during the earlier stages of this process X ray analysis shows that in addition to the change of parameter, the crystals in the aged material are in a disturbed state which is gradually relieved as the heating is continued This distortion of the space lattice is accompanied by an increase of the electrical resistance and is believed to be caused by the formation of minute particles of the precipitated compounds The precipitation of the dissolved substance from the supersaturated solution entails, first the rejection of the atoms of the dissolved metal from the lattice of the solid solution accompanied by the possible formation of molecules a process which entails a profound disturbance of the lattice In the second stage, which may follow closely upon the first and probably largely overlaps it, a coagulation of these rejected atoms or molecules takes place, resulting in the formation of minute crystallites This coagulation process, except perhaps in its earliest stages, by removing the dissolved metal from the matrix, will tend steadily to lessen the distortion of the lattice and thereby to diminish the hardness and the electrical resistance

It is interesting to note that if the age hardening is due to the precipitation of a metal, and not a compound of that metal, the hardening effect is small, for example, the iron copper alloys This would be expected on the basis of the theory outlined above, since it would cause less distortion of the lattice, no formation of molecules being required If the formation of a compound involves the combination of atoms of the solute with those of the matrix a greater distortion of the lattice will occur and the hardening be greater When however the compound is formed by the combination of two or more different solute atoms, then still greater distortion is to be expected and marked increase of hardness results Thus the ageing of an alloy with 4 5 per cent of copper due to the formation of $CuAl_2$ is relatively much less than that of one with 1 08 per cent of Mg_2Si

Although up to the present the existence of lattice distortion has been inferred on general grounds the new evidence from the X ray spectra of aged alloys provides complete confirmation and shows by the broadening of the lines that this disturbance occurs to a marked extent which varies with the degree of hardness and electrical resistivity attained at the successive stages of the process In the later stages of the ageing when coagulation has become appreciable and the precipitated substances have formed small distinct crystallites the electrical resistance begins to fall again the hardness diminishes and the lines in the X ray spectrum become less diffuse F C T

University and Educational Intelligence

CAMBRIDGE —Dr A B Appleton has been reappointed University lecturer in anatomy and Mr G F Briggs has been reappointed University lecturer in botany

Grants have been made from the Gordon Wigan Fund to Prof J E Marr Prof J Stanley Gardiner, Mr F I Brooks and Prof J Barcroft

Dr H R Dean professor of pathology in the University has been elected Master of Trinity Hall

A Syndicate was appointed in May 1928 to report on the position of mineralogy in the studies of the University This Syndicate has now reported to the University and has made the following recommendations (1) Two new departments should be created in place of the existing Department of Mineralogy, namely a Department of Crystallography and a Department of Mineralogy and Petrology (2) the Department of Mineralogy and Petrology should be closely associated with the Department of Geology, but should also work in co operation with the Department of Crystallography (3) the head of each of the new departments should be a professor and the minimum additional staff of each department should be one lecturer and one demonstrator (4) a new building should be erected for the Department of Mineralogy and Petrology adjacent to the Sedgwick Museum (5) the premises of the existing Department of Mineralogy should be assigned to the new Department of Crystallography, (6) crystallography should become a subject in Part I of the Natural Sciences Tripos but should carry a smaller maximum of marks than the existing subjects, (7) mineralogy and petrology should form part of the subject of geology in Part I of the Natural Sciences Tripos, either as an alternative to palæontology or in addition at the candidates option, and that in the latter case mineralogy and petrology together should carry the same additional maximum of marks as that allotted to crystallography, (8) that both crystallography and mineralogy and petrology should be included in Part II of the Natural Sciences Tripos, but that their relation to the other subjects, or to possible subdivisions of them, should be determined by the appropriate University bodies, (9) subject to the adoption of the above recommendations, the existing subject of

mineralogy in the Natural Sciences Tripos should be discontinued

LONDON —Presentation Day at the University was on May 8, the ceremony taking place in the Albert Hall, the Vice Chancellor, Sir Gregory Foster, presiding The report of the Principal (Dr Franklin Sibly), the last to be presented under the old constitution, records continued progress The number of candidates for all examinations attained for 1928 a record of 34,941, comparing with 11,937 in 1913 This number includes 3383 candidates for first degrees and 508 for higher degrees, a total of 3891, of whom 2357 were internal and 1534 external In the last year before the War, the numbers were 900 internal and 907 external The roll of internal students now comprises 9886 names Referring to the obligations of the Bloomsbury site, the Principal reported that four purposes had so far been approved—an administrative block, the Library, a Great Hall, and premises for the Union Society, in addition, eleven other purposes have been provisionally approved, including an Institute of Slavonic and East European Studies, towards which an offer of £35,000 £45,000 had been received and accepted from the government of Czechoslovakia, and provision for the teaching of the History of Art, for which Lord Lee of Fareham is collecting a fund

The Vice Chancellor, in welcoming the men and women who had become bachelors during the year, and those who had received higher degrees, appealed to the graduates to join Convocation and to use their voting powers when occasion arose "These things", he said, "in the past had been left to a small minority" The University has a body of 170 professors, 80 readers, and about 830 recognised teachers Next year the Union Society would have a Union House for the promotion of social life and the maintenance of their interest in University affairs Referring to the new statutes for the University, the Vice Chancellor said that the colleges and schools are now more closely federated with the University than before, and the symbols of this are the newly created Collegiate Council and the modification of the constitution of the Senate which has made it a more homogeneous body than hitherto, and the growth of the financial responsibilities has involved the creation of the University Court to deal mainly with finance

---

MR F S MARVIN will be conducting a history course at Danzig in the first week of August and has secured the co-operation of several scientific workers as well as historians and those interested in international affairs, which should make the twelve lectures as useful and comprehensive as any that have preceded them in the 'Unity' series The general topic is "The World of To-day", or "Progress in Ten Years of Peace". Mr. Marvin proposes to deal with general international relations since the War, and Rear-Admiral J D Allen, an expert on armaments and naval matters, will treat of that aspect of progress. Prof Doris Mackinnon, of King's College, London, will lecture on "Where we stand in Biology", and Mr L L White (author of "Archimedes", etc) is coming from Berlin to speak on the position of the physical sciences Other aspects will not be neglected and, as Danzig is a home of internationalism, it is hoped to secure the co-operation both of German and Polish speakers and listeners on education, art, and literature The Baltic trip offers in itself great attractions to visitors, and is too little known in England Danzig, to which passages may be booked direct from London, is the best centre. Full particulars may be obtained from the honorary secretary, Mrs. Innes, 29 High Oaks Road, Welwyn Garden City, Herts.

Calendar of Patent Records

May 18, 1804 —Gas lighting has a well authenticated history before the work of Frederick Albert Winsor, whose patent for an apparatus for making gas for lighting and heating was granted on May 18, 1804, but it was Winsor who first advocated the public use of gas lighting, and its supply and distribution from a central source Pall Mall was lighted by him in 1807, and the forerunner of the Gas Light and Coke Co was formed a few years later

May 20, 1800 —An early reaping machine was that for which a patent was granted to Robert Meares on May 20, 1800 A large pair of shears is fitted to a frame mounted on wheels Long handles are fitted to the shears and by these the apparatus is propelled and the shears operated Wires are arranged to guide the fall of the crop as it is cut

May 22, 1813 —William Brunton's 'steam horse' for propelling or drawing carriages upon roads or railways by means of levers or legs worked by a steam engine and acting alternately or conjointly against the ground, was patented on May 22, 1813 The engine worked successfully on the Newbottle colliery tramline and drew coals up an incline of 1 in 36, but was eventually wrecked by an explosion

May 22, 1834 —Baron Heurteloup patented on May 22, 1834, a self priming gun in which a long tube of detonating powder was contained in the stock and was moved forward into position by each fall of the hammer The hammer cut off the fragment of the tube required and then detonated the powder In 1836 Heurteloup petitioned the Privy Council for a confirmation of the patent as he had discovered that a similar arrangement had been previously patented in France in which a straw filled with detonating powder was used, though the action was different, the gun was not self priming, and the patent had apparently never been put into practice The petition was granted and the patent confirmed

May 22, 1847 —Sydney Smith of Nottingham solved the problem of the safe application of steam power by inventing and making the first efficient steam pressure gauge, the steam acting on a flexible diaphragm connected through mechanism with the needle of a dial The patent is dated May 22, 1847

May 23, 1829 —The accordion —the intermediate between the mouth organ and the concertina—was the subject of the Austrian patent granted on May 23, 1829, to Zyrill Demian and his two sons Karl and Guido, organ makers of Vienna The patent was originally for two years only, but was extended for another three years in 1831

May 24, 1834 —The chain grate mechanical stoker was first devised by John George Bodmer, and was included with other forms of the mechanical stoker in his patent No 6616, sealed on May 24, 1834 Bodmer described in his specification apparatus of the endless chain type, but his preferred form consisted of a number of separate carriages which were intermittently pushed forward and one by one discharged at the back end, to be returned rapidly to the front and fed with fresh coal for another passage through the furnace It was left to John Juckes, seven years later, to perfect the endless-chain type and introduce it into industry

May 24, 1847 —The fish plate joint now in universal use for the rails of railways was invented by W Bridges Adams, and was patented by him and Robert Richardson on May 24, 1847 Until its adoption, rails were butt- or lap jointed together in wide chairs

Societies and Academies

LONDON

Royal Society, May 9 —**R H Fowler** and **P Kapitza** Magnetostriction and the phenomena of the Curie point Various physical consequences of Heisenberg s theory of ferro magnetism are discussed The phenomena require the interaction integral called by Heisenberg J_0 to increase with the volume of the crystal at least over a small range of value covering the normal value for iron —**C G Darwin** A collision problem in the wave mechanics In the quantum theory the motion of matter can be regarded as a wave motion but this motion is interpreted in terms of particles in order to describe what is observed In an ideal experiment of this kind depending on collisions between two free bodies, the particle like behaviour is given just as successfully by the wave theory Thus the interpretation can sometimes be postponed —**J A Gaunt** The relativistic theory of an atom with many electrons The total angular momentum of the atom suitably defined, has the same properties as in the non relativistic theory The inner and magnetic quantum numbers, and their selection rules can therefore be taken over into the new theory —**R de L Kronig** The quantum theory of dispersion in metallic conductors —**N F Mott** The interpretation of the wave equation for two electrons As required by the relativistic equation proposed by Eddington the results of the two separate experiments required to locate each electron are independent —**G I Taylor** The criterion for turbulence in curved pipes Coloured fluid is introduced through a small hole in the side of a glass helix through which water is running C M White s conclusion from resistance measurements, that a higher speed of flow is necessary to maintain turbulence in a curved pipe than in a straight one is verified —**H J Phelps** and **R A Peters** The influence of hydrogen ion concentration on the absorption of weak electrolytes by pure charcoals Hydrogen ion concentration influences adsorption upon purified charcoal of various organic acids and bases and of some amino acids in varying degrees, sometimes showing a relationship to the degree of ionisation —**R K Asundi** The third positive carbon and associated bands The third positive carbon bands, the 3*A* bands and the so called Wolter spurious bands, have been photographed A complete vibrational analysis of the three systems shows that they have the same final electronic state —**F J Wilkins** The kinetics of the oxidation of copper (1) —**C E Eddy, T H Laby**, and **A H Turner** Analysis by X ray spectroscopy —**M C Johnson** The adsorption of hydrogen on the surface of an electrodeless discharge tube —**A Elliott** The absorption band spectrum of chlorine —**H W Thompson** and **C N Hinshelwood** The influence of nitrogen peroxide on the combination of hydrogen and oxygen —**H T Flint** The first and second order equations of the quantum theory —**S Bhagavantam** The magnetic anistropy of naphthalene crystals —**A H Wilson** Perturbation theory in quantum mechanics (2) —**C G Lyons** and **E K Rideal** On the stability of unimolecular films (1, 2 and 3) —**P A M Dirac** Quantum mechanics of many electron systems —**O W Richardson** and **P M Davidson** The spectrum of H_2 The bands analogous to the parhelium line spectrum (3 and 4) —**H E Hurst** The suspension of sand in water —**D Brunt** The transfer of heat by radiation and turbulence in the lower atmosphere —**W G Bickley** Hydro dynamic forces acting on a cylinder in motion, and the idea of a ' hydrodynamic centre —**M L E Oliphant** The action of metastable atoms of helium on a metal surface —**J Hargreaves** The effect of a nuclear spin on the optical spectra —**M N Saha** and **Ramash Chandra** New methods in statistical mechanics

Linnean Society, April 18 —**G Claridge Druce** A botanical tour in Cyprus The botanical history of Cyprus is a long one Theophrastus mentions some of its products Dioscorides alludes to its Origanum oil and Drummond in 1754 was the first to record a definite endemic species *Quercus alnifolia* a second, *Onosma fruticosum* was found by Labillardière in 1787 *Putoria* and the *Cedrus* had also thus early been noted Its true scientific exploration was began by Sibthorp in 1787 accompanied by his artist Bauer the discoverer of *Pinguicula crystallina* The new species were published chiefly by Boissier T Kotschy visited the island three times between 1840 and 1862 and brought up the number of species to 1050 Mr A Lascelles (now Sir Alfred) when he was judge there and his sister Miss Lascelles made considerable collections in 1900–2 The author verified some of the earlier records and added *Lamprothamnium papulosum* J Groves a great extension in the north east —**G S Carter** and **L C Beadle** Respiratory adaptations among fishes of the swamps of the Paraguayan Chaco As previously shown, the fauna is normally exposed to great lack of oxygen The fishes may obtain a further supply of oxygen from the well oxygenated surface film of the water and the air above the water Of the twenty species collected in the swamps eight breathe air and the remainder make use of the surface film by means of accessory organs Most of the excretion of carbon dioxide is carried on in the gills but the absorption of oxygen takes place almost entirely in the accessory organ This is due to the evolution of the accessory organs for life in a medium poor in oxygen, and not for migration out of the water It is suggested that in the evolution of the vertebrates aerial respiration was evolved in waters of this type as an adaptation to lack of oxygen while the fish was purely aquatic and that this development opened the way to the later changes definitely associated with the migration

BRUSSELS

Royal Academy of Belgium, Oct 13 —**P Stroobant** The meeting of the International Astronomical Union at Leyden, July 5–13, 1928 A general account of the work done at the meeting —**D V Jonesco** A theorem of Lord Kelvin (2) —**Victor Van Straelen** The triassic crustacean decapods and the origin of a phylum of Brachyura —**Henri Fredericq** The chronaxy of the muscles of insects From the measurements given the motor muscles of the wings of the dragon fly, humble bee, and blowfly must be considered as organs of moderately rapid function This idea, which is in contradiction with accepted ideas, can be explained, with Jarolimek if it is admitted that these muscles do not act directly on the wing —**Henri Fredericq** The chronaxy of the invertebrate heart (cephalopods and decapod crustaceans) The bathmotrope action of the visceral nerves of the octopus —**J E Verschaffelt** The determination of surface tension by the method of separating discs A discussion of the theory of the method and experimental figures for water, benzene, nitrobenzene, carbon tetrachloride, and aniline —**E Delporte** Discovery and observations of minor planets at the Royal Observatory of Uccle —**Em Vincent** Observations on the layers penetrated at the No 2 pits of the Eysden coal pit, near Maaseyck —**Armand Duchesne** The influence of the thermometer mass on the measurement of a constant tem-

perature or of one varying with time Experiments are described which support the contention that the temperature of a superheated vapour or of a gas can only be measured accurately with a thermometer of negligible mass

Nov 3 —**P Stroobant** A new calculation of the flattening of Saturn —**E Delporte** Discoveries and observations of minor planets at the Royal Observatory of Belgium —**Henri Fredericq** The action of the faradisation of the nearer portions of the ganglion nerve chain of the lobster on the chronaxy of the distant portions —**Victor Van Straelen** A new prosopon from the Diois Hauterivian and the Cretaceous 'Dromiacea' in general —**D V Jonesco** A theorem of Lord Kelvin (3)

LENINGRAD

Academy of Sciences (*Comptes rendus*, 1929, No 1) —**S Kostytschew** and **V Berg** The forms of calcium compounds in vegetable tissues The bulk of calcium in vegetable tissues is in the form of salts, mainly of oxalic, phosphoric, and carbonic acids, some of it is in complex combinations with organic substances, or in the form of salts absorbed by the colloid substances of the protoplasm No difference in the forms of calcium compounds found in leaves and in the organs devoid of chlorophyl was found —**N Gutkova** A mineral of the keffekilite group from the Tertiary deposits of the Crimea —**A N Kiritshenko** Contribution to our knowledge of the genus *Aphelochirus* (Hemiptera, Naucoridae) A list of 22 species of the genus is given and their distribution indicated on a map Two new species, *A improcerus* from Manchuria and *A ussuriensis* from the Ussuri land, are described and figured —**I Efremov** Finds of stegocephals in the north east of European Russia Four distinct places where fossil remains of stegocephals are found are described in detail —**A P Filippov** Deformation of elliptic plates with supported margins —**T Ščegoleva-Barovskaja** The first representative of the family Mordellidæ (Coleoptera) from the Jurassic deposits in Turkestan A new genus and species, *Præmordella martynovi*, representing a new subfamily Præmordellinæ is described

ROME

Royal National Academy of the Lincei, Feb 3 —**G D'Achiardi** Mode of formation of mimetic groups of dachiardite This mineral, found in the geodes of one of the pegmatitic veins traversing the granite of Monte Capanne, near S Piero in Campo, Elba, was termed mimetic zeolite, from its composition and from its occurrence in apparently octagonal prisms formed by the union of eight crystalline individuals The pseudo prismatic groups have an upper funnel shaped end, either closed or open at the centre The origin of this structure is discussed —**L Petri** Behaviour of the olive under the influence of uranium radiations and of ionisation of the air The stimulating action of ionised air on the growth of the olive is neutralised by the radiations emitted by the green oxide of uranium, when these exceed in intensity a certain limiting value —**G Vitali** Bianchi's identity for Riemann's symbols in generalised absolute calculus —**A Signorini** Electrostatic interpretation of the Kutta-Joukowski theorem —**L Fantappié** Functional operators and calculation of infinite matrices in the quantum theory (2) By means of the notion of a symmetrical or hemisymmetrical functional product and, in general, of the notions of the theory of analytical functionals, it is possible not only to replace all the symbolic formations (mostly divergent series) used in the calculus of matrices due to Heisenberg, Born, and Jordan, by so many integral formations of well defined significance, but also to reduce the whole matrix calculus to the calculus of symmetrical composition of the functions of two variables co ordinated to the matrices themselves —**A De Mira Fernandes** Superficial transports —**Silvia Martis in Biddau** Investigation of a rational expression for the powers of a matrix of the third order —**Ines Saciotto** Riemann symbols in generalised absolute differential calculus —**B Colombo** Certain theorems regarding the generalised transformations of Darboux —**A Carrelli** Broadening of bands by resonance (1) The causes for the broadening of spectral lines are numerous When, for example, the concentration of sodium atoms is diminished, the effect of resonance becomes annulled, but the pressure or Stark effect begins to preponderate, this effect being proportional, not to the number of atoms of the same kind, but to the total number of atoms or ions of any kind present in the flame Moreover, when the concentration is extremely small, the line, although having zero breadth from the Holtzmark effect or the effect of pressure, has a finite breadth by auto extinction or by the Doppler effect, and hence there should be a zone of values for the concentration in which anomalies in behaviour foreseen by Holtzmark become apparent Such a zone may be readily realised experimentally —**M Amadori** Condensation products of glucose and *p* anisidine Like *p* phenetidine, *p* anisidine condenses with glucose, giving two products, one, melting at 86°, having a glucosidic constitution, and the other, melting at 140°, the constitution of a Schiff's base —**G Malquori** Conductivity of mixed solutions of lead and ammonium nitrates The formation of complex compounds, assumed to be a probable cause of the solubility relations of solutions containing lead and ammonium nitrates, is confirmed by a study of the electrical conductivities of such solutions —**A Tulli** Chemical analysis of a mummy contribution to the study of mummification Examination of a mummy from the Vatican Museum which, although bearing an inscription indicating it to be that of a lady of noble birth, was that of a man, points to the use of natural balsams in the mummifying process —**Maria Bergamaschi** Absorption of carbon dioxide by means of roots, and its utilisation in chlorophyllic synthesis The results of experiments on maize and other plants show that plants grown in an atmosphere absolutely devoid of carbon dioxide form starch in their leaves by utilising the carbon dioxide absorbed by their roots from the soil or from the nutrient solution surrounding the roots Plants grown in this way from seeds contain a greater amount of carbon than the seeds themselves, and are, therefore, able to 'organicise' carbon dioxide absorbed through the roots The objection that, in such cases, the organic substance is formed entirely at the expense of the carbon dioxide furnished by respiration is thus refuted These results are of both physiological and practical importance, and indicate the value of supplying carbon dioxide to the roots as well as to the leaves —**G Quagliariello** Investigations on the mechanism of lymph formation The differences in chemical constitution and in chemico physical properties between lymph and plasma may be explained to some extent by assuming that, between the two liquids separated by a membrane far more permeable to electrolytes than to colloids, there is a tendency to the establishment of a membrane equilibrium It is not, however, contended that the relationship between blood and lymph is completely represented by a simple system of this kind, as it is recognised that lymph is formed, not only from the blood but also from the tissues, which may be able to withdraw from the lymph one element in preference to another

Diary of Societies.

FRIDAY May 17

Royal Sanitary Institute (at Town Hall Devizes), at 5.30 —R. T Rhodes and others Discussion on The Milk and Dairies Order 1926. —L. B. Densham and others Discussion on Meat Inspection.

Royal Photographic Society (Pictorial Group, Practical Meeting), at 7

Royal Society of Medicine (Obstetrics and Gynaecology Section) (Annual General Meeting), at 8.—Dr H. R. Spencer A Straight Rod Pelvimeter —G I Strachan Some Contraindications to Radiotherapy in Carcinoma of the Uterus.—V Bonney Results of the Surgical Treatment of Carcinoma of the Uterus.

SATURDAY May 18.

Royal Sanitary Institute (at Town Hall Devizes), at 10 A.M.—H R. Hooper and others Discussion on Some Aspects of Local Government on Air Water and Sewerage —A. W Jakeway and others Discussion on The Devizes Sewage Works and Small Type Refuse Destructor

MONDAY May 20.

Cambridge Philosophical Society (in Cavendish Laboratory), at 4 30 —Dr H. Jeffreys On the Transport of Sediments by Streams —Dr B F J Schonland A New Electroscope —J Hargreaves (a) The Dispersion Electrons in the One Electron Problem (b) Some Calculations Relevant to the Quantum Defect in the Extended Ritz Formula. —S E A Landale An Analysis of Triode Valve Rectification —*Papers to be communicated by title only* —J A. Chalmers An Approximate Method of Determining the High Velocity Limits of Continuous β ray Spectra —L Roth Jacobian Surfaces of Quadrics in Four Dimensions —L Rosenhead Systems of Double Rows of Line Vortices in a Channel of Finite Breadth where the Axis of the Row is Parallel to the Axis of the Channel —J R Wilton On Ramanujan's Arithmetical Function $\Sigma_{r,s}(n)$.—P L Srivastava On the Phragmén Lindelöf Principle —Dr A C Dixon The Second Mean Value Theorem in the Integral Calculus —R A. Frazer A Proof of Miquel's Theorem by Involutions in the Argand Diagram

WEDNESDAY May 22

Royal Society of Medicine (Comparative Medicine Section) at 5 —Annual General Meeting

Eugenics Society (at Linnean Society) at 8 —Dr R A Fisher Prof T E Gregory and others Discussion on Are Family Allowances Eugenic in Effect?

Institution of Water Engineers (at Birmingham).

THURSDAY May 23

Imperial College Chemical Society (in Main Chemistry Lecture Theatre Royal College of Science), at 5 —Prof R Robinson The Chemistry of the Indole Group

Institute of Pathology and Research (St Mary's Hospital), at 5 —Prof W W C Topley The Natural Acquirement of Immunity

Royal Aeronautical Society (at Royal Society of Arts), at 6 30.—F A Foord Lubrication of Aircraft Engines.

Faraday Society (Annual General Meeting) (at Chemical Society), at 7 45 —At 8 —J C Hudson Third (Experimental) Report to the Atmospheric Corrosion Research Committee of the British Non Ferrous Metals Research Association

Royal Society of Medicine (Urology Section), at 8 30 —Annual General Meeting

Institution of Water Engineers (at Birmingham).

FRIDAY May 24

Linnean Society of London (Anniversary Meeting), at 3 —Presidential Address and Presentation of Linnean Gold Medal to Prof H de Vries

Royal Society of Medicine (Disease in Children Section) (Annual General Meeting) at 5 —Dr F J Poynton Some Phases in English Pediatrics as viewed by a General Physician

Physical Society (at Imperial College of Science), at 5 —Dr Ezer Griffiths A Hygrometer for Use in Timber Seasoning Kilns —Dr J H Vincent Experiments on Magneto-strictive Oscillations at Radio Frequencies.

Royal Institution of Great Britain at 9 —F J Rennell Rodd The Tuareg Tribes of Central Sahara

Institute of Chemistry (Edinburgh and East of Scotland and Glasgow Sections) (jointly with Society of Chemical Industry—Edinburgh and East of Scotland and Glasgow Sections) (at Glasgow) —Prof G G Henderson Recent Research in the Terpene Series

Institution of Water Engineers (at Birmingham).

SATURDAY May 25.

Institute of Chemistry (Edinburgh and East of Scotland Section) (jointly with Society of Chemical Industry—Edinburgh and East of Scotland and Glasgow Sections) (at Glasgow)

CONFERENCE.

May 18 to 21

Association of Teachers in Technical Institutions (at Liverpool).

PUBLIC LECTURES.

TUESDAY May 21

University College at 5.30 —Dr R. Flower Life History and Folk lore of a Kerry Island. (Succeeding Lectures on May 28, June 4 and 11.)

THURSDAY May 23

University College, at 2.30.—Sir Flinders Petrie Recent Discoveries at Beth Peleth, Palestine. (Lecture to be repeated on May 31 at 5 30, and on June 1 at 3.)

University of Birmingham, at 4.—Dr H C Cameron Some Types of Septic Infection in the Newly born (Ingleby Lectures). (Succeeding Lecture on May 30.)

FRIDAY May 24.

Birkbeck College, at 5.30.—Prof. S. de Geer Sweden and the North of Europe. (Succeeding Lectures on May 28 and 30)

SATURDAY, MAY 25, 1929

Competition and Progressive Industry

COMPETITION in a general sense is easily defined, and the dictionaries are fairly clear and consistent in their meaning In the strictly economic sense also there has hitherto been little difficulty The American economist Walker, for example, is very precise and definite in his description of the essential nature of competition Competition, he says, signifies the operation of individual self interest among the buyers and sellers of any article in any market It implies that each man is acting for himself solely, in exchange, to get the most he can from others, and to give the least he must himself Competition is opposed to combination in any form, to custom, and to sentiment, even though these, especially the two latter, in actual business have always played a part

No one to day believes, however, in the possibility of pure and unalloyed competition, wholly unrestrained and unregulated Not only does it exist, of itself, in many varied forms and manifestations, but also it has been profoundly affected by the introduction of ethical and moral considerations, many of which have acquired the force and status of law Moreover, other great forces have sprung into existence and rapidly developed of late years, such as co operation and combination, the formation of trusts and cartels and of vast international conglomerations, whereby the original conception of competition has either been pushed entirely into the background or has been transformed beyond recognition The question is thus raised in an acute form What is the real essence and purpose of competition in industry to day? What part, if any, does it seem destined to play in the future? Can it be reconciled and fit in with the new changes and new forces, or is it being transformed out of existence?

Much confusion of thought on these questions arises from the divergent views held in regard to industry itself and its proper place in the scheme of things The socialist attitude, for example, towards competition will be very different from that of the individualist, and again, those who disbelieve in industrialism altogether will certainly entertain the utmost loathing for competition, the most powerful instrument of progress It is therefore necessary, at the outset, to make a philosophical distinction, and decide whether we believe in progress or not, whether we have a profound faith in the Baconian philosophy of 'fruit' or in the Diogenic doctrine of the tub, with its reduction

of wants and satisfactions to a minimum It is not necessary at this time to deal with the larger question of progress and its would be philosophical critics, or to frame an elaborate apologetic of modern industry It will be taken for granted that progress, with all its errors and blind gropings and possibly mistaken ideals, is desirable and indeed inevitable, that it is not necessarily soul deadening materialism, but can be made subservient to the highest intellectual and moral interests and activities of mankind It will be shown that competition can play a vital and increasingly nobler part in that progress

In regard to the socialist attitude, it is of interest to quote J Stuart Mill's incisive condemnation thereof—and he of all men, cannot be charged with undue harshness to the socialists He says

I utterly dissent from the most conspicuous and vehement part of their teaching, their declamations against competition With moral conceptions in many respects far ahead of the existing arrangements of society, they have in general very confused and erroneous notions of its actual working, and one of their greatest errors, as I conceive, is to charge upon competition all the economical evils which at present exist They forget that wherever competition is not, monopoly is, and that monopoly in all its forms is the taxation of the industrious for the support of indolence, if not of plunder Instead of looking upon competition as the baneful and anti social principle which it is held to be by the generality of Socialists, I conceive that, even in the present state of society and industry, every restriction of it is an evil, and every extension of it, even if for the time injuriously affecting some class of labourers, is always an ultimate good To be protected against competition is to be protected in idleness, in mental dullness, to be saved the necessity of being as active and intelligent as other people"

This no doubt is far too sweeping, and, while showing up the error of the socialist view, commits serious blunders of its own Every restriction of competition is not of course necessarily an evil nor is every extension thereof an ultimate good nor is every form of monopoly always evil In fact, neither Mill nor the socialists have found the real truth Both competition and monopoly require proper regulation and control, when both may be highly beneficial It is not indeed by any means certain that unrestrained monopoly is a greater social evil than unrestrained competition, though strangely enough, and through a most remarkable form of mental aberration, free competition has been held by some, for example, the framers of American anti-trust legislation, to be sacrosanct and above reproach, whilst monopoly has been anathematised as everything that is bad Under the latter misguided view the whole basis of patent law, among other things, is thoroughly wrong and unsound But a full discussion of monopoly and all its implications must be deferred

In its natural and original sense competition means the struggle for existence, issuing in the survival of the fittest It dominates biology and the theory of evolution, and when Herbert Spencer applied evolutionary doctrine to social phenomena it was taken over almost in its entirety—with all its crudeness and cruelty—by the economists, at least for a time Huxley seems to have been among the first to see that this was going much too far He realised the necessary checks to the full force of competition which must be imposed by the social framework within which it acts Social progress", says Huxley, means a checking of the cosmic process [of ruthless competition and struggle] at every step, and the substitution for it of another which may be called the ethical process, the end of which is not the survival of those who may happen to be the fittest in respect of all the conditions which exist (environment), but of those who are ethically the best" Thus an ethical aspect was introduced, and thus incidentally we see also that the question, Who are fittest to survive? to which reference will be made later, is involved

Prof Gide's definition is When each individual is at liberty to take the action he considers the most advantageous for himself, whether as regards the choice of an employment or the disposal of his goods, we are living under the regime of competition But this takes too much for granted and lacks precision, for, strictly speaking, robbery with violence, or piracy, or fraud and cunning, are not excluded It is therefore clear that competition must keep within the law, most of which—written and unwritten—can be summed up in the good old sporting phrase, "Play the game, and take no mean advantage of a rival" Moreover, we no longer believe in the blind uncontrolled evolution of society We believe it is possible to set definite aims before us, for example, in regard to race improvement and the ultimate attainment of the highest type of manhood No longer is everything to be sacrificed to the accumulation of wealth, we place man first, and with this profound change in aim there is a change in the rules of competition Slavery has been abolished, piracy does not now figure in honourable competition, the labour of young children is condemned, the hours of work of adult men and women have been reduced. The

cruelties of the cosmic struggle are being constantly mollified by rising ethical and moral standards What may be called the 'plane of competition' has been raised to loftier heights, and much has been left behind and below in the process Piracy and all that it means, the arbitrament of force and cunning, has fallen outside of and below that rising plane, and has been replaced by other mighty forces working strongly for social betterment Of these forces, co operation, *or the enlargement of the competitive group*, is among the greatest

At first sight it would appear that increasing co operation means decreasing competition, but this is probably a superficial misconception There has been co-operation from the beginnings of things Even among animals, with the struggle for existence at its keenest, there is, nevertheless, a certain amount of mutual agreement and help among the members of a group or community What has happened in modern times, with growing co-operation, is a difference in degree rather than in kind the competitive group has become larger, and new groups have been formed This coalescing into groups, political, economic, scientific, and the like, is one of the most characteristic phenomena of modern society, and its reaction on competition is of profound interest One of the results so far is an infinite variety of competitive groups, and although the competition, as between different groups, may be keener than ever, it is also cleaner, and the effect on an individual is softened and modified, not only by association with others in the group, but also by a rising tide of sympathy, benevolence, and public humanitarianism expressed both through law and custom, and the group is thereby strengthened Darwin realised this clearly enough He says

"Animals endowed with the social instincts take pleasure in one another's company, warn one another of danger, defend and aid one another in many ways These instincts do not extend to all the individuals of the species, but only to those of the same community As they are highly beneficial to the species they have probably been acquired through natural selection"

In human affairs, however, the groups are getting larger, are reaching out rapidly to international dimensions This is a stern fact of our times, and we see not as yet clearly whither it will lead us, or how it will end It is the greatest and most perplexing problem of the age But one thing at least seems perfectly clear. If we take for examination any one particular group, say, a trade union of workers in any one industry, do we not see that the grand idea of co operation is not necessarily antagonistic to or mutually destructive of competition, that competition, in one very important direction, may be retained in full force, namely, *in the terms of admission to the group*? Membership of a group in most professions, and formerly in the old trade guilds, is or was a guarantee of a certain standard of workmanship and character It is surely in the best and highest interests of a group or union to maintain a high standard It would still be possible to permit of several grades within the group, and the good workman should not be penalised and brought down to the level of the inferior, or the latter unduly bolstered up to heights beyond his deserts As we have already seen, even J Stuart Mill would allow no weak sentiment, no excess of humanitarian zeal, to thwart the exercise of this salutary principle

In regard to another important manifestation of industrial grouping, namely, that of the trust and international combine, and its effect on competition, it is only possible to refer here very briefly to one or two points It is now generally agreed that complete monopoly is very difficult of achievement, and even if achieved it must be subject to control by the State But the form of control, as the Federal Trade Commission of the U S A has found, presents great practical difficulties The combine itself, however, and also the trade association, is finding that, in its own best interests, it must put service to the public before exploitation, and that control should be exercised so far as possible from within rather than imposed from without Hence it is that there is now much talk of ethical rules and standards by trade associations, especially in the U S A, and that unfair methods adopted by any member should justify the expulsion of that member from the group Here again the competitive principle may be applied in the selection of the right men to control the destinies of the group, and perhaps also by the imposition of certain conditions and standards of membership This also applies to the co operative societies in all their manifold forms

It is being increasingly realised, even by the most powerful combine, that trade is healthiest and most flourishing when built up, not on selfish aggrandisement but on service, good quality, and moderate prices, and those groups are 'fittest to survive' who take their stand on these adamantine foundations Competition of the right kind is still the mainspring of progress, but it is constantly rising to higher levels, and implies worthy struggle for the things that matter

History of Biology

The History of Biology a Survey By Erik Nordenskiöld Translated from the Swedish by Leonard Bucknall Eyre Pp xii + 629 + xv + 16 plates (London Kegan Paul and Co, Ltd, 1929) 25s net

A SYSTEMATIC historical account of the development of biology has long been a desideratum, and, as Dr Raymond Pearl says of the German edition, the blank has been admirably filled by Erik Nordenskiöld" The author is a trained original worker in zoology, whose experiences, among others, ranged over the shores of the North Sea at the St Andrews Marine Laboratory, and whose zeal, erudition, and scientific accomplishments enabled him to deal with the subject no less adequately than his facile pen portrayed

The task undertaken by the author was one of no ordinary magnitude, involving infinite labour and careful judgment in addition to an extensive and sound knowledge of biology, so that he was enabled to grasp the trend of the labours and epitomise the main facts or theories of the writers from various points of view, as well as bestow sound criticism The work is divided into four heads (1) Biology in classical antiquity, (2) biology during the Renaissance, (3) biology in the seventeenth and eighteenth centuries, (4) biology during the first half of the nineteenth century The author centres in Babylon, that ancient home of civilisation, the early acquaintance with the subject from contact with animals—though Oriental wisdom was largely composed of the mystical and the magical—matured and developed by a powerful priesthood The Egyptian and Israelitic, the Hindu and Chinese conceptions followed Amongst the earliest scientists of Greece, again, were the Ionian philosophers, some of whom, like Thales, regarded water as the cause of all things—even the earth coming into being from its condensation, whilst living forces were evolved by a kind of primordial procreation in the mud The influence of the philosopher Pythagoras on scientific development was great, as also was that of Plato, who laid the foundation of biological systematisation The early medical writings of Greeks, such as those of Hippocrates (the Great) "on air, water, and places", and the belief that the body was composed of four elements—fire, air, water, and earth—closed the period of natural philosophers' speculations Yet about this time human osteology was studied so far as the skeleton, the brain, nervous system, the eye, ear, and the urogenital system

The advent of Aristotle, one of Plato's students, and the greatest biologist of antiquity, meets with ample treatment He upheld the domination of form, that is, of the spirit, over matter, and of motion as the origin of all things As a prolific writer on biology, metaphysics, statesmanship, and art, his influence was great He interested himself in marine as well as land animals, indeed, the former are better represented in his works than the latter His evolution was a product of divine wisdom, whereas that of Democritus was the dominion of necessity

The anatomists of Alexandria and those of Arabia next come under review, and thereafter Pliny and Galen are dealt with, as well as the condition of science in the Middle Ages Moreover, the institution of universities in the twelfth century as growths from the cathedral schools was a noteworthy development As the pupils at these schools increased in number the teachers combined to form what was termed a *Universitas magistrorum*, and thus the Universities of Paris, Oxford, and Leipzig were founded

During the latter part of the Middle Ages biology was often prominent, though the writings of Aristotle were chiefly followed, and a compilation of the literary material of the past was common One man, however, resolutely fought the schoolmen and their antiquated views, this was Roger Bacon, and he led the way to the future Renaissance Nature was now to be studied unfettered by Church dogmas and scholastic systems, and thus biology reached results far beyond those of Aristotle or Galen Ushered in by the "Novum Organum" of Francis Bacon, a number of distinguished authors in zoography, anatomy, medical science (including dissection), such as Vesalius and Fabricius, led up to the epoch making discovery by Harvey of the circulation of the blood, which ousted from the field all the previous erroneous views

The end of the seventeenth and the eighteenth century was marked by the appearance of mechanical Nature-systems such as those of Descartes, Hobbes, and Spinoza, yet Boyle, the first modern chemist, and Newton, the illustrious discoverer in mathematics and optics, flourished The end of the seventeenth century saw the discovery of the lymphatic system and notable advances in anatomy and physiology, the author consistently giving to each discoverer a due meed of praise—the result of his own industry in master-

ing their researches Names familiar to every student of biology, such as Leeuwenhoek and Malpighi, are crowded in this great period in the history of anatomy The beginning of the eighteenth century saw a further series of able workers, commencing with Sydenham and Hoffman (the latter holding that matter and motion formed the foundations of existence), to Swedenborg's investigations of the brain

Before the advent of Linnæus, attempts to classify plants had been made by Cesalpinus, Tournefort, and Ray, the "Historia plantarum generalis" of the latter forming an important treatise He also wrote two zoological works of note, and, besides his later publications, which were extensive, he made advances in realising the difference between species and genus, and he had a keen eye for natural groups

In the treatment of Linnæus the author's skill in epitomising the salient features of a distinguished man's career are conspicuous He shows that Linnæus possessed an extraordinary capacity for observing natural objects and surroundings, and such he used in the various important works, for example, the 'Systema Naturæ" His plant system and his binomial nomenclature are amongst his most successful performances The account of Buffon and his friend Daubenton follows, the theoretical ideas of the former and the anatomy of the latter bearing important fruits

The advance of natural science in the eighteenth century by Réamur, the experimental and speculative biology of Haller, Bonnet's parthenogenesis, Wolff's generation theory and epigenesis and other noteworthy features of the period are fully dealt with Descriptive and comparative anatomy by Albinus and Camper, as well as the labours and the museum of John Hunter, carry us to Pallas, zoologist, botanist, and traveller—all receiving careful treatment Modern chemistry and its influence on biology is then considered, whilst critical philosophy and romantic conceptions of Nature follow Kant, Fichte, Goethe and his metamorphosis of plants are all ably criticised, as also Oken's natural philosophy, Erasmus Darwin and his "Zoonomia", E G St Hilaire and his fundamental type of vertebrates

We now reach biology in the first half of the nineteenth century—a period in which a galaxy of eminent comparative anatomists occur—from Vicq d'Azyr to De Blainville, two names being especially familiar, namely, Lamarck and Cuvier, though all are noteworthy Lamarck, from his numerous works, is looked on as a pioneer of modern biology His life theory is motion, and he asserted that spontaneous generation goes on incessantly under heat, light, and electricity Cuvier's chief investigations were in the vertebrates—both living and extinct To the last he held to the immutability of species and to the incomparability of types Bichat and De Blainville both accomplished important work Embryology received great advances, especially experimentally, workers in microscopy and cytology were numerous, others in the field of geology also made great strides Then came Darwin, whose sketch gives another example of the author's method and fairness to the great naturalist, his supporters and opponents His theory early found a home in Germany, championed by Gegenbauer and Haeckel, and his influence compelled a whole generation everywhere to follow his line of thought

The discovery of microbes by Koch, the work of Anton Dohrn at Naples, the researches on heredity and descent, the advance of experimental biology, and distinguished workers who followed Mendel, or extended biochemistry, conclude this remarkable book with its thirty two portraits of ancient and modern biologists The author, indeed, has accomplished a task almost as formidable as that of his distinguished uncle in surmounting the North East Passage W C M

Medieval Devil Worship

The History of the Devil the Horned God of the West By R Lowe Thompson Pp xiv + 172 + 8 plates (London Kegan Paul and Co, Ltd, 1929) 7s 6d net

It is interesting as well as instructive to reflect that, even at the beginning of the present century, it was not an uncommon thing to find the religious practices of primitive peoples described in the pages of missionary magazines as 'devil worship', and the term is still frequently ascribed in popular language to the Voodoo rites of Haiti The missionary of to day will not be responsible for a like crudity, but his predecessors in stigmatising what was outside the pale as the province of the Adversary, was following the precedent of the early Church For the early Christians the devil was a very real problem Not only had eastern religion and philosophy made familiar the opposition of the good and evil principles, the Church was constantly confronted with the problem of backsliding, more often than not involved in the performance of civic duties Further, the Christians were the more harsh in their condemnation because they themselves in

their attitude to the world of spirits were not far removed from the pagans, even though they worshipped other gods

Therefore heretics, whatever their heresy, were ensnared by the devil, Manichees, gnostics, and the like were not merely theologically in error, they were actively worshippers of the evil one, their assemblies orgies of debauchery—scenes such as Walter Mapes describes writing of the Patarini, when indeed he seems to be attributing to these heretics nothing more than an inversion of the Christian agape or love feast Most of the accusations of blasphemy brought against the witches show the same lack of imagination and were formulated by a simple inversion in every detail of the practice of the Church Whether or not these accusations had any foundation in fact, the practices thus recorded are not pagan ritual unless the sexual licence is regarded as a fertility rite The sacrificial meal in the circumstances points no more in one direction than the other In fact, if the Bull of Innocent VIII be taken as defining the medieval witch, it appears that outside certain popular conception of magical powers—blasting crops, casting spells on cattle and persons, and the like, ideas common to all primitive peoples—the distinguishing mark of the witch is the compact with the devil This is purely a theological conception which can be traced back to the early days of the Church So far there is support for those who hold that witchcraft was a form of heresy which threatened the existence of the Church and therefore exonerates it from the odium of a persecution which grew out of a baseless superstition

To the average modern the medieval mind is a closed book Of all its manifestations the witchcraft persecutions are the most difficult to understand Any investigation or theory which can help to bridge the gap between modern times and the Middle Ages deserves to be weighed before it is rejected It is for this reason that Miss Murray's book on the witch cult in Western Europe and now Mr Thomson's book on the devil are welcome They offer theories which, to an anthropologist at least, come within measurable distance of an intelligible formula, of a cause for action which, if not such as moves the modern educated mind, is at least intelligible at a certain stage of culture Mr Thomson, with Miss Murray, believes that witchcraft was a system of religious worship with a regular ritual, meaningless in its medieval context, which had survived from a primitive fertility cult Of this the central figure, the devil, was in earlier times the Celtic horned god Cernunnos, a figure in turn derived from the masked figures of palæolithic art, and in particular the well known *sorcier* of the Trois Frères cavern at Les Eyzies The horned tailed figure of the last named must inevitably recall the horned medieval devil

Mr Thomson supports this view by a wealth of argument, but there are difficulties For one thing, there is a lengthy gap between palæolithic times and the Cernunnos of the Iron Age It is difficult to believe in a popular cult entirely submerged for that length of time Further, is Cernunnos himself indubitably indigenous to Western Europe? The cult of the goat in connexion with witchcraft did not reach Britain Is that because it had a Mediterranean origin and distribution only? There is, however, this much to be said for the view, that there was something of the nature of a popular cult at the back of witchcraft It is difficult to explain away the evidence in the English trials, and some of the Scottish and Continental evidence, on any other view The actual words of the confessions seem to convey the convictions of the speakers and seem to be too consistent *inter se* to be hallucinations If it were not for this the whole witchcraft persecution and the devil cult might be more properly regarded as an inglorious, if logical, climax of the whole body of previous Christian theology and ecclesiastical history

Mr Thomson follows the lead of the devil along many entertaining by paths Among his modern instances his account of the recent case of the Abbé Desnoyers, near Melun, would have gained in interest had he told the whole story This remarkable case was really a battle between two cults In this, as in the previous case six years before, the original offence which gave rise to the accusation of witchcraft was not in the details given in the courts which Mr Thomson quotes, but in the fact that an image of the Madonna which shed real tears and belonged to Mme Mesmin, on whose behalf the Abbé was attacked, had been made by him to cease to function

Neurology and Psychology.

The Matrix of the Mind By Prof Frederic Wood Jones and Prof Stanley D Porteous Pp xi + 457 (Honolulu, T H University Press Association, London Edward Arnold and Co, 1928) 21*s* net

THE two authors of this unusual book, one an anatomist, one a psychologist, set out to blend the "subject matter and viewpoints of two sciences neurology and psychology". As they point

out in the preface, the ordinary text book of psychology makes little or no attempt to relate the structure of the brain to its function Neurology, however, comprises more than the facts of the structure of nervous system, and the author of the first portion of the book (that dealing with structure) has produced a most readable general review of comparative neurology in both its structural and functional aspects The evolution of the neopallium, the portion of the brain believed by the morphologist to be the cortical structure concerned with the complex correlation of the different sensations, and therefore probably the organ of mind, is traced through the vicissitudes in the phylogenetic development of the sense organs The reflection of animal behaviour upon the sense organs, and consequently upon their nervous connexions, is illustrated by many particularly entertaining and original accounts of the behaviour of some of the Australian fauna in relation to the structure of their brains

This means of approach to the study of mind reveals, however, that the morphologist has to restrict himself to wide generalisations in the relation of behaviour to structure It is evident that, just as the morphologist is unable to deduce from the structure of the nervous system of a certain frog that it will react to the sound of a splash by diving into water, so the psychologist cannot, at present, base any but the most gross errors in mental make up on any structural alteration Nevertheless, since the evolution of behaviour does carry with it recognisable structural changes, there is presumably some structural basis, as yet unknown, underlying minor changes in behaviour in any one particular species, and it would therefore seem profitable to make the utmost use of such structural alteration as can be found in cases of human psychological abnormality

The second portion of the book (dealing with the psychological aspect) is disappointing from this point of view, for little attempt is made to enlarge upon the behaviouristic significance of the morphology of the sense organs and the neopallium in connexion with psychology and psycho-pathology Instead, the working of the mind, with the usual discussion of sensation, attention, and behaviour, in terms of the outworn physiological principles of ‘facilitation’ and ‘synaptic resistance’, is here further involved in new functional theorems such as the “theory of neural counter currents” deduced from physiological statements which are inaccurate, and a theory of the origin of motor and sensory decussations which is difficult to harmonise with the appearance of such decussations very low in the animal scale, but also entirely disregards the nature of the sensory pathways except for the number of times they cross the central axis An admirable feature of the whole book, however, is the emphasis which it lays on the necessity for adequacy of stimulus in appraising reaction

Our Bookshelf

Bird Watching on Scolt Head By E L Turner Pp viii + 84 + 47 plates (London *Country Life*, Ltd, 1928) 10*s* 6*d* net

IN the present volume Miss Turner gives us the results of her two years' watching on Scolt Head, one of the sanctuaries run by the Norfolk and Norwich Naturalists' Society Miss Turner is one of those very few people who possess not only keen powers of observation, a wonderful knowledge of bird life, with an immense store of energy and perseverance in carrying out any work upon which she embarks, but, fortunately for us, also has the ability to set forth the results of her work in a most charming manner

Naturally, everyone will not agree with all the opinions which Miss Turner expresses, but, even where we disagree with them, we shall be none the less interested in what she tells us, or the less pleased with the manner in which she does it Scolt Head is now undoubtedly one of the most interesting sanctuaries in the whole of Great Britain, both on account of the many birds which breed there and because it forms a wonderful resting ground for migratory birds on both their spring and autumn travels Miss Turner's work lay principally with the breeding birds, but during her long months' vigils she lost no opportunities of dealing also with the visitors to her island, and the oldest observers may learn something from her work on Scolt Head Even the keenest of Nature lovers make slips sometimes, and we should like to have seen the dwarf fire crest which Miss Turner says measured only 2½ in *across* the wings, perhaps she meant 4½ in

The book is profusely illustrated with very beautiful photographs, both of the birds themselves and of the scenery in which they live, the paper on which the text is printed is good and light, and the book is a pleasure to read without being a labour to hold

(1) *Atomic Structure as modified by Oxidation and Reduction* By Dr W C Reynolds Pp viii + 128 (London Longmans, Green and Co, Ltd, 1928) 7*s* 6*d* net

(2) *La structure du noyau de l'atome, considérée dans la classification périodique des éléments chimiques* Par Charles Janet Pp 67 + 3 planches (Beauvais Imprimerie Departementale de l'Oise, 1927) n p

(1) THERE are no problems of greater interest at the present time than those of atomic structure as elucidated by the study of emission and absorption

spectra This study has the merit of providing a rigid experimental basis for chemical doctrines of valency and of molecular structure, but the author ignores all this valuable material and prefers to rely on imagination rather than on knowledge of the behaviour of electrons In these circumstances a responsible teacher might well be excused if he advised his students to seek wisdom elsewhere, and to spend their money in purchasing a real romance from the learned pen of Mr J J Connington (who, we believe, is in private life a professor of chemistry), rather than spend both time and money in an effort to distinguish between fact and fancy in Dr Reynolds's tables of atomic structure

(2) A similar criticism can be made of Janet's study of the structure of the nucleus At a time when the relevant energy levels are being deter mined experimentally from the properties of β rays, the value of a purely imaginative study of the distribution of electrons and protons in the nucleus is surely negative rather than positive, since it represents a dissipation of energy which might have been converted into useful work

Contributions to Analytical Psychology By C G Jung Translated by H G and Cary F Baynes (International Library of Psychology, Philosophy, and Scientific Method) Pp xi + 410 (London Kegan Paul and Co, Ltd, New York Harcourt, Brace and Co, Inc, 1928) 18s net

IT is several years since Jung's "Psychological Types" was published in this series, and the present volume is the first of the author's works to appear in English since then It is well known that there is, under the name psycho analysis, no common body of doctrine which is held by its most distinguished representatives Attempts have been made to show that the theories of Freud and Jung, for example, are not so antagonistic as they seem One such attempt constitutes a volume in this same series But Jung himself can scarcely keep within the bounds of polite language in denouncing the Freudian sex hypothesis as a fanatical creed The volume before us is full of interest from cover to cover, and it well exemplifies what the reviewer regards as Jung's reasonableness and sanity He applies his theories to problems of modern life, in cluding women in Europe, marriage as a psycho logical relationship, analytical psychology and the poetic art, and analytical psychology and education It is to be noted that, apparently on the principle that one cannot touch pitch without soiling one's fingers, Jung eschews the term 'psycho analysis' He prefers the term 'analytical psychology'

Der Bau der Erde eine Einführung in die Geotektonik Von L Kober Zweite neubearbeitete and vermehrte Auflage Pp iv + 499 + 2 Tafeln (Berlin Gebrüder Borntraeger, 1928) 27 60 gold marks

THE first edition of this work appeared in 1921, and was a series of discussions of tectonic problems rather than a text book This present edition practically amounts to a new work, for much of the arrangement, terminology, and substance is new The book now consists of five hundred pages compared with the three hundred of the first edition Prof Kober justly claims the present work as the first text book of geotectonics The book certainly stands alone, it is approached by some recent German publications, but there is nothing in English of the same calibre

The author, starting with the division of the earth's crust into kratogenetic (stable) and orogenetic (mobile) zones, proceeds to discuss these divisions with respect to facies, movements, and mountain building The results are applied to the continents and oceans in turn Finally, many theories, such as those concerning the origin of continents and oceans, are summarised The book is up to date, it includes, for example, an account of Stille's work in Saxony, of G M Lees' work in the Persian Gulf, and of the results obtained by the *Emden* during echo sounding cruises in 1927

The typography is good, illustrations adequate, and misprints few The bibliography is not up to the standard of the book, and an index would have been useful for a volume of this size

Recent Advances in Hæmatology By Dr A Piney (Recent Advances Series) Pp x + 318 + 4 plates (London J and A Churchill, 1928) 12s 6d net

THE demand for a second edition of this book within twelve months of the appearance of the first is an indication of its well deserved popularity Dr Piney has made additions to every chapter, in order to include the most recent views on all aspects of his subject, and a new chapter is given describing the spleen in various infections

The author considers hæmatology on an essenti ally morphological basis Modern views on blood chemistry are therefore not included, and, as is pointed out in the preface, the term hæmatology is not generally intended to cover the subject of serology Treatment is discussed in relation to each disease or group of diseases, little progress has been made recently in this direction, but the administration of liver in the treatment of pernicious anæmia is mentioned The glossary is very useful to those not familiar with pathological terms, and there are numerous references to original articles and text books

A Manual of Elementary Zoology By Dr L A Borradaile (Oxford Medical Publications) Sixth edition Pp xvi + 683 + 25 plates (London Oxford University Press, 1928) 16s net

THE principal alterations in the sixth edition of this excellent and well produced text-book are the revision and extension of the chapters on sex, embryology and evolution A "concise account"—about a page—of the snail (*Helix*) has been added, but this is too short to be really serviceable It contains no description either of the reproductive apparatus or the ganglia—the former is simply noted as "complicated, hermaphrodite" and the latter as "concentrated into a clump around the gullet" The figure of the senile form of *Entamœba* with buds might have been omitted

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

The Mass-Spectrum of Lead from Bröggerite

IN the issue of NATURE for Mar 2, 1929, Dr Aston gives the results of his determination of the mass spectrum of a sample of lead in the form of its tetramethyl compound, of which the lead had been extracted by us from a sample of Norwegian broggerite We obtained the lead in the form of chloride, and took particular care to have it free from impurities The conversion of the chloride into tetramethyl was kindly carried out for us by Mr S C Witherspoon, and care was taken to test all chemicals and reagents used to see that they were free from lead

Dr Aston discusses his results and reaches interesting conclusions, and a further discussion is given by Sir Ernest Rutherford It may be of interest to consider the matter further, in the light of our analysis of the mineral

The specimen was obtained from a trustworthy dealer and bore the label "Uraninite var Broggerite, Karlshus, Raado, Smaalenene, east of Kristianiafiord, Norway" It appeared to be homogeneous except for a little pink feldspar, mica, and quartz, and was of an iron grey colour and of the general appearance of massive magnetite, but with some crystal faces Close examination showed no evidence of its having been acted upon by weathering processes Our analysis is as follows

U_3O_8 = 72 12 per cent	equi-		U = 61 158 per cent
ThO_2 = 4 98 ,, ,,	valent		Th = 4 377 ,, ,,
PbO = 8 64 ,, ,,	to		Pb = 8 018 ,, ,,

We have confidence in the essential accuracy of these figures

For calculating the age we used the formula given by the International Critical Tables of the National Research Council

$$\text{Age} = \frac{\log (U + 0\ 38\ Th + 1\ 156\ Pb) - \log (U + 0\ 38\ Th)}{6\ 5} \times 10^{11} \text{ years} \qquad (I)$$

This gives an age of $919\ 5 \times 10^6$ years for this mineral Changes which might be made because of some variation in the values of the disintegration constants involved in the factor 6 5 of the formula are not likely to be of large amount The calculated age is in good agreement with previous determinations by others on uranium minerals from the same general locality We may now compare this value with results obtained by making use of Dr Aston's figures in connexion with our analytical results

Dr Aston gives the figures 86 8, 9 3, and 3 9 as the percentage values obtained for Pb^{206}, Pb^{207}, and Pb^{208} present in the lead tetramethyl Of these isotopes of lead, the first and second have presumably been derived from uranium and its isotope actino uranium, and the third from thorium In analysis, uranium^{238} and actino uranium are necessarily determined together as 'uranium', and their disintegration has resulted in Pb^{206} and Pb^{207} respectively Calculations of age from these elements, disregarding thorium and Pb^{208}, should give practically the same result as the original calculation, and these results in turn should agree with the result that thorium and Pb^{208} give For uranium plus actino uranium we express the formula as

$$\text{Age} = \frac{\log (U + 1\ 156\ Pb^{206+207}) - \log U}{6\ 5} \times 10^{11} \text{ years} \qquad (II)$$

and get

$$\text{Age} = 908\ 4 \times 10^6 \text{ years}$$

This may be considered a satisfactory agreement with the $919\ 5 \times 10^6$ years previously obtained

For thorium and its lead we have

$$\text{Age} = \frac{\log (0\ 38\ Th + 1\ 156\ Pb^{208}) - \log (0\ 38\ Th)}{6\ 5} \times 10^{11} \text{ years} \qquad (III)$$

From this calculation, however, we get the result

$$\text{Age} = 1313 \times 10^6 \text{ years},$$

which is widely different from the previous figures

It is pertinent to inquire as to the probable cause of the discrepancy

In Dr Aston's account he expresses some uncertainty as to relative intensities of the lead lines, and gives a margin of possible error of ± 2 for Pb^{208} In view of the small total quantity of Pb^{208}, this means a large percentage error, the possible variation running from 5 9 to 1 9 per cent and corresponding ages (calculated by formula III) running from 1900×10^6 to 671×10^6 years The limits of error, therefore, include the value $919\ 5 \times 10^6$ deduced from the original calculations, but if this is accepted as correct, Dr Aston's figure for Pb^{208} apparently requires correction to bring it into harmony The limits of error he himself sets likewise point to the desirability of greater refinement of photometric measurement in order to make the results serve for age calculations Instead of 3 9 per cent of Pb^{208} given by him, our figures indicate 2 64 per cent, which is obtained by substituting in formula III the age $919\ 5 \times 10^6$ years and the analytical value of thorium, and solving for Pb^{208}

There is, however, another aspect of this matter which should be considered Formula III involves the factor 0 38, accepted as expressing the disintegration equivalence of thorium in terms of uranium It may be thought that it is this factor which should be revised, as there has been some variation in determinations of the value of this quantity among different experimenters As a basis for judgment in this matter we may make a new calculation of the conversion factor from the data supplied by Dr Aston For this purpose we combine formulæ II and III in the form

$$\frac{U + 1\ 156\ Pb^{206+207}}{U} = \frac{x Th + 1\ 156\ Pb^{208}}{x Th} \qquad (IV)$$

and solve for x

Such a calculation does not involve the correctness of the constants in the uranium series, but only the value of the conversion factor required to get identical results for the uranium series and the thorium series

Proceeding in this manner, we get the result 0·57 Possibly it may be regarded as an open question whether the accepted value 0 38 obtained by direct measurement by physicists does not require correction to bring it into closer accord with the figure 0·57 derived from Dr Aston's work, but in reading Dr Aston's letter we are left with the impression that Dr Aston himself does not wish to be held too strictly to the numerical values that he gives

Furthermore, previous work by one of us (*Amer Jour Sci*, November 1928) has given support to the substantial correctness of the figure 0·38 Two

minerals from a certain deposit in Brazil were analysed, after taking means to remove weathered products One was a uranium mineral carrying little thorium, and the other was a thorium mineral carrying almost no uranium From the results the ages were calculated using for thorium the equivalence ratio 0 38 The ages found for the two were in close agreement

The investigation of which the results have been reported by Dr Aston, was suggested (by C S P) in the hope of obtaining a direct determination of uranium lead (Pb^{206}) and thereby improving the accuracy of the existing formula for calculating ages It was also hoped that the uranium thorium equivalence factor (0 38) could be independently determined and perhaps improved, in order that the determination of geological ages might be rendered more certain From a consideration of the matter in the light of the analysis, it seems probable that a higher degree of precision in the measurement of the intensity of lead lines will be necessary in order to attain these ends We hope that future work by Dr Aston will bring this about In any event we are happy to know that our sample has been useful to Dr Aston in finding fairly conclusive evidence of the existence of actino uranium

Estimates of the Ages of the Whin Sill and the Cleveland Dyke by the Helium Method

THE helium method of measuring geological time originally devised by Lord Rayleigh has hitherto been applied only to minerals or other materials that were found to be relatively rich in the radioactive elements, uranium and/or thorium It is already well known that the results obtained are to be regarded as minima on account of the special tendency of accumulated helium to escape from such specimens during their exposure to the atmosphere and during their preparation for analysis This tendency is necessarily most marked in old and richly radioactive minerals like uraninite and thorianite, in which large quantities of helium have been generated (for example, 10 c c per gm) In very feebly radioactive materials, like ordinary igneous rocks the amount of helium is correspondingly minute (for example, about 10^{-4} to 10^{-5} c c per gm), and its proportion to that of other gases (about 1 c c per gm) is very low The ordinary gases of an igneous rock are not appreciably extractable by a pump, even when specimens are ground *in vacuo*, nor, as a rule, do they begin to escape in appreciable quantity as a result of heating, until the temperature exceeds 300° C It is therefore to be anticipated that the loss of helium from specimens of close grained igneous rocks awaiting analysis will be much less serious than that from radioactive minerals

The technique introduced by the late Sir William Ramsay, and developed by Prof Collie and by Lord Rayleigh, for the determination of minute traces of helium has recently been still further improved by Prof F Paneth and, independently, by Dr R W Lawson It is now possible to measure with a reasonable degree of accuracy the helium accumulated in ordinary igneous rocks, even if their geological ages date from epochs no more remote than those of the Tertiary In the case of plateau basalts, possibly some 40 million years old, the average radium and thorium content is such that the accumulated helium should be of the order 10^{-5} c c per gm With modern methods amounts down to 10^{-8} c c can be estimated, and therefore quantities of the order found in rocks and ordinary rock forming minerals are readily determinable

With these considerations in mind the helium method has been successfully applied to two north of England rocks (the Whin Sill and the Cleveland Dyke) that have recently been under detailed petrological investigation (A Holmes and H F Harwood *Min Mag*, 21, pp 493 542, 1928, and 22, pp 1 52, 1929) The determinations of radium and thorium were carried out (by V S D) in the laboratories of Prof H Mache at the Radium Institute Vienna, while those of helium were done in Prof Paneth s laboratories in Berlin (also by V S D) The materials used for these determinations were in each case parts of the specimens already analysed chemically and mineralogically in the course of the investigation to which reference has been made The following are the results obtained

Rocks Investigated	$Ra \times 10^{12}$ gm /gm	$U \times 10^{6}$ gm /gm	$Th \times 10^{6}$ gm /gm	$He \times 10^{6}$ c c /gm
Whin Sill Scordale Beck, Westmorland (No 551)	0 27	0 81	3 0	36 0
Cleveland Dyke Bolam Co Durham (No 402)	0 61	1 83	6 1	11 0

The approximate age (omitting a negligible time correction for the wearing out of uranium and thorium during the life time of the rock) is given by the formula

$$\frac{He}{U + 0\ 29\ Th} \times 8\ 5 \text{ million years,}$$

where U and Th are the percentage contents of the rock in uranium and thorium, and He is the volume in c c of helium at N T P in 100 gm of the mineral (A Holmes and R W Lawson Factors involved in the Calculation of the Ages of Radioactive Minerals *Amer Jour Sci*, April 1927, pp 334 5)

From the data of the above table the ages are found to be

Whin Sill	182 million years
Cleveland Dyke	26 million years

The Whin Sill was injected into the Carboniferous rocks of the north of England in very late Carboniferous times The Cleveland Dyke was injected in post Liassic time, and the recognition of its definite status as an outlying member of the Mull dyke swarm points more closely to an early or middle Tertiary age The numerical ages are thus seen to be in excellent agreement with the geological evidence They also conform quite satisfactorily with the scanty results based on lead ratios The latter give 192 million years for the late Carboniferous (Joachimstal pitchblende provisionally corrected by atomic weight evidence for primary lead), 36 million years for the (?) late Miocene (brannerite from Idaho, uncorrected), and 66 and 52 million years for the late Cretaceous (pitchblendes from Colorado and Wyoming respectively, also uncorrected)

While it is probable that the helium results may be slightly low, it must be remembered that there is no real proof of this, for the lead ratios cited are themselves not yet so securely founded as one could wish There may be traces of primary lead in the Tertiary and late Cretaceous pitchblendes of North America, and, if so, the figures given would be too high The Joachimstal evidence, while generally consistent, suffers from the fact that the specimens analysed were

not the specimens from which lead was separated for atomic weight determination

Clearly there is a vast field of geological research now open to investigation by the long neglected helium method If our initial hopes are realised—and these preliminary results provide ample encouragement—a method is now available for dating all fresh igneous rocks which have not been heated up or metamorphosed since they came into place There should not be the slightest difficulty for example in distinguishing Carboniferous dykes and sills from those of Tertiary age It should be equally easy to settle with certainty the controversy as to whether the Carrock Fell complex belongs to the Ordovician or to some later epoch of igneous activity There are many such problems awaiting solution in every country where igneous rocks occur Moreover since igneous rocks suitable for the helium method are far more abundant and far better distributed in time than are radioactive minerals suitable for the lead method there is now available a practical means of effecting long distance correlations and of building up a geological time scale which checked by a few reliable lead ratios here and there should become far more detailed than could ever be realised by means of the lead method alone

Further work is in progress on the north of England rocks and it is our intention as soon as possible to begin the systematic prosecution of this extremely promising line of research Dr R W Lawson has consented to collaborate in the work by making the helium determinations and by carrying out a quantitative investigation on the possibilities of escape of helium in various circumstances

A Case of Siamese Twins in the Spiny Dogfish (*Squalus fernandinus*)

THE occurrence of a case of Siamese twins in fishes has, so far as we are aware not previously been recorded The present example was recently discovered by one of us (J M) amongst the material collected during the survey of the Cape seas by the s s *Pieter Faura* about twenty five years ago Unfortunately, no records of the finding of this abnormality appear to have been kept and one can therefore only speculate as to how it was originally found

It is well known that this particular species of dog fish is viviparous, the female giving birth to as many as half a dozen young at a time In the dissection of the uterus of a gravid female, the young are found to be fully developed except for the possession of a yolk sac, which in these cases takes on the function of a yolk sac placenta, being in intimate contact with the wall of the uterus, which appears to be specially folded to receive the surface of the yolk sac At birth, the young is born fully developed, the yolk having been completely absorbed, the yolk sac having shrivelled up

In the Siamese twins', as is well shown in the accompanying photograph (Fig 1), the umbilical cords are still present, each embryo being provided with one One is struck by the position of these cords, which here have their exit in the neighbourhood of the pectoral girdle as opposed to the normal abdominal position The integument and the muscles surrounding the bases of these cords were incomplete, so that a large opening was left for the exit of the cords, the coelom thus being in direct communication with the exterior

The fact that the umbilical cords were still visible externally—the yolk sacs had apparently been broken off for they are entirely absent from the specimen—leads one to the conclusion based on the advanced state of development of the new born young that the twin was found during the dissection of the uterus of a gravid female

FIG 1 Siamese twins (spiny dogfish)

A brief description of the external appearance of the abnormality may prove of interest The anterior ends as far back as the pectoral fins are free being attached to a single trunk and tail Thus we find that there are a pair of pectoral fins to each free thoracic part while the first and second dorsal fins are symmetrically developed in their normal positions Spines are developed in front of each dorsal fin The tail presents a peculiar appearance The caudal fin is double symmetrically developed about the median horizontal axis The part corresponding to the ventral lobe of the caudal fin of a normal individual is twisted through a plane of 90° so as to lie in the horizontal instead of the vertical plane This lobe of the caudal fin is also shown in Fig 1 Along this side of the caudal region a deep groove is continuous from this fin up to a line through the posterior ends of the second dorsal The other caudal lobe is entirely absent The ventral fins are a single pair which has become displaced so as to lie laterally on one side of the trunk Each on its inner surface has a well developed clasper, while the single anus is also displaced and lies between the bases of the ventrals

The two heads are apposed by their ventral surfaces each being perfectly normal the mouths and nostrils facing each other The normal five pairs of gills are also present on each head

FIG 2 —Transverse section along line A B of Fig 1 to show duplication of the vertebral column etc *c* centrum *gr* groove *h.a.* hæmal arch *l a* lateral arch *m* myomeres *n a* neural arch *n sp* neural spine *sc* spinal cord

It has not yet been possible to make a detailed dissection of the specimen but a transverse section across the tail, just behind the second dorsal fin shows that the vertebral column is double each column appearing symmetrical about the median horizontal plane A vertebra of each column consists of a centrum, the neural arches forming the neural canal in which the nerve cord lies and ending in the neural spine On the side of the groove above referred to, there appears a single lateral arch with spine lying against the base of the groove enclosing a lateral blood vessel The two centra are separated by a space bounded above and below by the centra on one side by the laterally placed arch, and on the other by a sheet of cartilage This space is divided by a horizontal membrane to form two hæmal arches in which the caudal veins and arteries run

We hope to make a detailed dissection of the various

internal structures in the near future in order to examine the various parts and to ascertain which are duplicated and which single.

The Past Cold Winter and the Possibility of Long-range Weather Forecasting.

MODERN meteorology has made notable advances in forecasting the weather of the next day; but when it attempts to predict the weather for more than a week ahead, the percentage of successes does not exceed fifty at the most. One reason for this failure is to be found in the refusal of the modern meteorologist adequately to take into account in the problem of weather prediction of direct terrestrial influences such as that of the physical state of the surface waters of the oceans, even though he may be ready enough to take such an influence into account when dealing with one of those aerodynamical problems—for example the life history of an Atlantic 'depression'—which he regards as lying within his particular province. Another reason is his neglect of the 'Polar Front' theory of Prof. Bjerknes, one of the greatest authorities on aerodynamics and hydrodynamics.

Prof. Bjerknes regards the polar regions as caps of cold air maintained largely in consequence of the local accumulations of ice and snow, offering a kind of cold circular wall facing the warmer winds of temperate latitudes. He considers that in conjunction with the strongly heated equatorial regions, they set up a circulation which brings warm air aloft from the equator to the pole, there to be cooled and to sink, weighed down by its increasing density, until it is absorbed into the polar cap; that these reservoirs of cold air at the poles are constantly discharging their accumulated air towards the equator along the earth, in accordance with 'impulses' supplied by the region of low barometer around the equator; that the trade winds represent successful attempts on the part of such accumulations of polar air to reach the region of equatorial calms. He supposes, further, that the cyclones of the North Atlantic arise through the mixing of the cold and warm air masses along the margin of the polar cap (the so-called 'polar front').

It is clear that a great simplifying theory such as this offers a basis for long-range forecasting of the weather in our latitudes. If we accept the theory, it is not difficult to see that the general character of the weather over long periods may follow changes in the extent and shape of the region of cold sea, for the polar caps must, in the long run, coincide with the regions of coldest water. For example, the presence of a tongue of warm water projecting into Arctic regions, such as the so-called Gulf Stream of the North Atlantic, will push this boundary back towards the pole, and cause contrasts such as are offered in winter by the cold climate of Labrador and the relatively mild climate of Iceland.

We may consider now whether the past severe winter cannot be connected with some modification of the normal temperature of the seas within the area of exceptional cold. The immediate cause of the severe weather has clearly been the persistence of northerly and easterly winds over Russia and Central Europe circulating round an 'anticyclone' or region of high barometer over Scandinavia and Finland, which anticyclone has generally been separated from the area of high pressure that normally covers Siberia in winter by a region of relatively low pressure over Russia. Now Prof. Witting found in the Baltic in the summer of 1927 a layer of cold water at a depth of about 10 fathoms, beneath the very warm surface water, heated by the sun, having altogether a volume much greater than that of a whole normal year's outflow from the Baltic into the North Sea, and having a temperature about 10° F. lower than the average. The surface waters of the Baltic are derived ultimately from the mixing of the river water with that finally ascending from such deeper layers, and this cold water might well chill their surface waters, and the air in contact with them, for two years or more, in accordance with the time that the water might be expected to take in passing away along the Norwegian coast.[1] Such chilling would cause the anticyclones which are so apt to form over Scandinavia to be more than usually persistent, as has been the case this winter. In this way the action of the cold water, which is far too small to produce directly a degree of cold such as has been observed, may do so indirectly through the agency of the wind, and the resulting accumulations of ice and snow will carry the process still further.

It seems clear that if the action of a single sea such as the Baltic can be so great, there is a great field open for international co-operation in the systematic study of the physical states not only of the Baltic but also of all the seas and oceans in and around Europe, including the Caspian and the Black Sea. This should be done once a year if not twice, and the results should be published quickly, so as to be available for long-period weather forecasting. This was in fact the policy of the International Council for the Exploration of the Sea before the War. It is hoped that the remarks that I have made will show that permanently to abandon such a scheme may be to throw away the opportunities of saving millions of pounds that would be afforded by the prediction, in good time, of winters such as that of 1928–29.

W. J. PETTERSSON.

Refraction of Light Waves by Electrons.

IT is an established fact that wireless signals transmitted from any place are readily received at the diametrically opposite place on the globe. The explanation usually given of the phenomenon is that the ions in the Heaviside layer make the speed of propagation of the waves greater in that layer than in the ordinary air below and thus bend the waves round the earth by a process of refraction. Larmor has developed the mathematical theory of the refraction (*Phil. Mag.*, December 1924), and has shown that if c is the velocity of light in vacuum and c' in the presence of electrons, then c and c' are related by the equation

$$c'^{-2} = c^{-2}\left(1 - N\frac{e^2\lambda^2}{\pi m}\right),$$

where N is the number of electrons per unit volume, e and m are the charge (in e.m.u.) and the mass of an electron, and λ the wave length. Assuming $\lambda = 10^5$ cm. for radio waves, calculations show that an electron density of 0.3 per c.c. is enough to produce the observed bending round the earth.

In the case of light waves, λ is of the order of 10^{-5} cm. This will lead to a large value of N in order that light waves may bend round the earth. If the refraction of light waves by electrons is to be observed in the laboratory, the curvature of the rays has to be much larger, and hence a still larger value of N will be required.

So far as we are aware, the bending of light waves by electrons has neither been attempted nor its possibility discussed. For some time past we have been

[1] The brackish water leaving the Baltic by the Oeresound and the Belts afterwards forms the 'Baltic current' along the west coast of Sweden and Norway.

experimenting to detect this effect, but before trying the actual experiment we thought it worth while to discuss if, under ordinary laboratory conditions, it is possible to obtain a sufficiently dense cloud of electrons to produce observable bending of a light beam. The results of our theoretical deductions are here set forth.

Langmuir has shown (*Phys. Rev.*, April 1923) that the density of space charge (ρ_0) at the surface of a plane hot surface is given by the equation

$$\rho_0 = 19260 \times i_0/\sqrt{T} \text{ e.s.u. per cm}^3$$

where i_0 is the saturation current expressed in amperes per sq. cm. of the hot surface at temperature T °K.

The density of space charge (ρ) at a distance y from the surface is also given by

$$\rho = \rho_0/(\sqrt{2}\,L_0\,y + 1)^2$$

where $I_0 = 4.59 \times 10^5 \times T^{-\frac{3}{4}}\sqrt{i_0}$ cm^{-1} expressed in amp. A thoriated tungsten filament of diameter 0.155 mm. and containing 1 per cent. ThO_2 gives an electronic current of about 20.5 amp./cm.^{2} at temperature 2300° K. (cf. Langmuir, *Phys. Rev.*, October 1923). If we take a strip of thoriated tungsten giving this current at this temperature, then ρ_0 will be equal to 8232 e.s.u./cm.^{3} and the density N of electrons at the surface of the hot strip is found to be 1.724×10^{12}. Also since $L_0 = 6258$ (approximately) the density (N) of electrons at a distance y is $1.724 \times 10^{12}/(8850y + 1)^2$. The expression shows that the electron density decreases rapidly with increase of distance from the strip. This variation of density will produce a curvature in a beam of light passing over the surface of such a strip. Since to a first order of approximation the refractive index $\mu = c/c = 1 - N e^2\lambda^2/2\pi m$, the curvature of the beam at a distance y from the strip will be

$$-\frac{d\mu}{dy} = \frac{e^2\lambda^2}{2\pi m}\,\frac{dN}{dy} = -\frac{4.6 \times 10^{-5}}{(8850y + 1)^3}$$

for sodium light $\lambda = 5.8 \times 10^{-5}$, the negative sign indicating that the beam will bend away from the strip.

At the surface of the strip ($y = 0$) the curvature of the beam will be numerically equal to 4.6×10^{-5}. If we assume that this curvature is maintained throughout the passage of the light over the whole length of the strip, say 10 cm., then the light beam which on entering the electron atmosphere just grazes the surface of the strip at one extremity will on emergence at the other extremity be shifted through a distance of 2.3×10^{-3} cm. from the surface. This shift will evidently be greater than the actual shift, since the expression for the curvature given above shows that it is not constant but that it diminishes rapidly with the increase of y—the distance from the strip. A more detailed calculation shows that the actual shift will be approximately equal to 7.8×10^{-4} cm. This shift, though small, should be detectable if suitable experiments can be arranged.

The smallness of the shift is due to the fact that the emitted electrons are mostly concentrated near the surface of the strip. At a distance of only 0.1 mm. the electron density falls to one ten-thousandth part of its value at the surface. A more favourable condition for bending the light beam will possibly be set up if the electron cloud is pulled upward by a positively charged plate held a few millimetres above the surface of the hot strip.

An Experimental Investigation of the Thermal Relations of Energy of Magnetisation.

THIS note is a first report of experiments undertaken for the purpose of determining the mechanism of the degradation of energy which accompanies magnetisation in ferromagnetic substances. The present experimental method consists in observing the change in temperature of a test specimen produced by a change in the magnetising force at consecutive intervals in a single cycle of magnetisation.

The test specimen is in the form of 106 bars of soft steel drill rod 1 mm. in diameter. The bars are so mounted as to form 8 coaxial concentric cylinders, and the lengths of the cylinders are so determined as

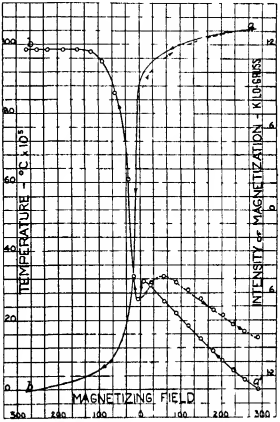

FIG. 1.

to give the aggregate the form of an ellipsoid of revolution the minor and major axes of which are 3.4 cm. and 60 cm. respectively. 106 copper bars of the same dimensions alternate with the steel bars in the structure. 106 thermocouples are constructed by connecting adjacent copper and steel bars alternately with 3 mm. lengths of No. 40 copper wire and No. 34 constantan wire. A coil around the centre of the ellipsoid permits the evaluation of the total magnetic flux in the specimen. The entire specimen is imbedded in rice powder and placed in an evacuated, silvered glass tube. Adequate thermal insulation isolates the latter from the magnetising solenoid in which it is placed.

The stability of the entire electrical and thermal system is indicated by a zero shift of 2 mm. per hour on a scale 6 metres from the thermocouple galvanometer. A measure of the uniformity of the magnetising field in the ellipsoid is obtained by connecting

half the thermocouples (associated with the inner bars) in opposition to the other half In these circumstances a reversal of the full magnetising field, which produces a rise in temperature of the steel corresponding to a galvanometer deflection of 220 mm, yields a deflection of only 4 mm

The results of the investigation are given by the accompanying curves (Fig 1) where intensity of magnetisation and temperature are plotted against true magnetising field Curve *ab* is the upper part of the usual 'hysteresis loop' for the steel The dotted portion indicates the loop obtained when the impressed field is reduced to zero and then restored to its former value The curve *a b* shows the total change in the temperature of the steel at every stage in the process of demagnetisation and reversal of magnetisation The dotted curve shows the total change in temperature corresponding to the process indicated by the dotted portion of the hysteresis curve

The not inconsiderable cooling of the steel in the neighbourhood of zero magnetising field, as well as the continued cooling accompanying remagnetisation on the upper part of the hysteresis loop are notable features of this record

Mine Lighting and Retinal Sensitivity

In the review of Dr Whitaker's recent book on 'Mine Lighting' in Nature of Mar 2, p 310 reference was made by the reviewer to the causes of miner's nystagmus I have not had the opportunity of examining the book myself, and therefore do not know what factors are considered to be most significant in producing this troublesome ocular disease

In my own investigations, however I have discovered several actions of light upon the retina which are probably of fundamental importance in this connexion When the retina is stimulated by white or coloured light with an intensity below a certain critical value—*a* intensity—an inhibitory reaction is evoked which depresses the sensitivity of the visual receptors, whereas if the light is above that value their sensitivity becomes enhanced Thus a feeble light of *a* intensity is doubly harmful, first, because the intensity is too low for comfortable vision without eye strain, and, second because its reflex action is inhibitory in character

In coal mining the source of light is of low intensity and the reflecting power of the coal surface is also low It can scarcely be doubted, therefore, that the intensity of light reaching the retina is below the threshold enhancing value, and thus it maintains the receptors in a much depressed condition

The prevailing view of the visual functions of the spectrum has been to regard all colours or wave frequencies as factors contributing only to the formation of the white sensation Undoubtedly they have this effect, but it is far from being the whole truth, or perhaps even the most important part of the truth Each wave frequency is an energy stimulus of a distinctive physiological character the complete functions of which are yet unknown I have found, however, that the enhancing power of violet light above the *a* intensity is about seven hundred times as great as that of yellow Thus it follows that since violet contributes very little to the illuminating power of a light, its chief use when above *a* intensity is to act as a sensitiser of the retina for the reception of the illuminating colours, a function which it performs with extraordinary efficiency

I have seen it stated that during the War the Admiralty found the ability to distinguish objects on the sea at night or in feeble illumination was much increased by previously stimulating the observer's eyes with violet or blue light This is to be expected from the extraordinary enhancing power of violet light Probably the same procedure would be beneficial wherever observations are to be made with weak light, such as in the use of the microscope or in counting scintillations, etc

In mine lighting under present conditions the lamp seems to have too low an illuminating power and is probably greatly deficient in the sensitising violet rays On both accounts the retinal sensitivity is greatly depressed Under such conditions visual acuity and luminosity contrast on which it depends are both diminished in value

Possibly the miner's optical troubles could be diminished or even eliminated by obtaining an illuminant which will supply violet rays of the required intensity, and by raising the illuminating power of the light above the threshold enhancing value, which for white light appears to be about 0 25 metre candle

Possibly much improvement could be obtained even under present illuminating methods, if it is not impracticable, by preparing a quickly drying white material which the miner could smear over the coal face at which he is working, and so obtain the full benefit of such light as he possesses

Variations in Sex Expression in *Ranunculus*

We have now been working on problems connected with andrœcial and gynæceal variation in *Ranunculus* for several years and wish to supplement the remarks by Mr J Parkin in his letter published in Nature of April 13, p 568

Plants of *R acris* and *R bulbosus* with the stamens partially or entirely deficient in pollen production, and with correlated reduction in the size of the flowers, have long been known There are many scattered references in botanical literature to this condition Thus an interesting note on the subject was published in Nature so long ago as 1878 (vol 18, p 588), and other references are given in Knuth's "Handbook of Flower Pollination', ii 18, 24 (Engl transl 1908) and by Sorokin, *Genetics* (12, 59, 1927) Varying grades of 'femaleness' were noted by us at Kew in 1914 in three species of the genus, but the War and accumulation of work immediately after prevented experiments being carried out, though one of us mentioned their occurrence in a paper published in the *New Phytologist* (18, 254, 1919)

We have found all grades between plants with completely hermaphrodite flowers and those with no functional stamens The occurrence of every possible intermediate has made the work of scoring extremely difficult and, to a certain degree, arbitrary On the other hand, our method of scoring led to Whyte's interesting and important discovery of the time-factor as a cause of the appearance of hermaphrodite or unisexual flowers Little purpose can be fulfilled by giving a Latin name to the composite group of sex variations

Mr Parkin, rather surprisingly, does not refer to the living plant he kindly sent us This was a male plant, in that all its flowers were, and have each season remained, functionless on the female side It is the most interesting buttercup we have yet seen and it has been used in genetical experiments to

produce generations not yet scored beyond the F_1. The flowers have an increased number of narrow petals and, in general appearance, recall those of *R. ficaria*, yet it is certainly *R. acris*. The plant has been multiplied vegetatively, and good specimens are preserved in the Genetical Herbarium at Kew. So far as we know it is the only 'male' *R. acris* plant ever recorded.

We are inclined to think that Mr. Parkin's suggestion that *R. acris* is in the incipient stage from hermaphroditism to gynædiœcism (or even to complete diœcism) is not improbable. We made a similar suggestion in a paper on the genetics of *R. acris* and *R. bulbosus* recently sent to press. Our field observations have proved that in some populations—widely scattered in England and Scotland—the percentage of female or intermediate forms is very much higher than one per cent, and in some counts it even approximated to fifty per cent.

Lastly, we wish to ask any reader observing sex forms or any abnormalities in any British species of *Ranunculus* to send us living specimens for genetical and cytological analysis.

The Arc Spectrum of Phosphorus.

THE arc spectrum of phosphorus has been investigated by Saltmarsh and by McLennan in the Schumann region, and the lines belonging to the fundamental transition $2M_2(M_2 \leftarrow\!- N_1)$ have been arranged according to Hund's theory by McLennan (*Trans. Roy. Soc. of Canada*, vol. 21, sec. 3, 1927).

The lines belonging to the second group of transition $2M_2(N_1 \leftarrow\!- N_2)$ lie, according to the horizontal comparison method of Saha and Majumdar, in the region ν 9400–10300–10800 (*Indian Journal of Physics*, September 1928, p. 72). Similarly, the lines due to the transition $2M_2(N_1 \leftarrow\!- O_2)$ have been located at 18000–20518.

The spectrum of phosphorus in the infra-red region has not yet been investigated, but as both silicon and sulphur are present in the sun, it was assumed that phosphorus should also be found. Taking the infra-red solar lines as given in the "Revision of Rowland's Preliminary Table of Solar Spectrum Wave-lengths," I located these lines with the aid of known differences $\Delta P_{1,2} = 151$, $\Delta P_{2,3} = 249$, in the regions predicted. The $4P - 4S_2$ lines and $4P - 4\bar{P}$ lines due to the transition $2M_2(N_1 \leftarrow\!- N_2)$ have been found at $\nu = 10555$ to 11095. Attempts are being made to verify the identification by taking a spectrum of phosphorus in this region.

The second group of lines, $2M_2(N_1 \leftarrow\!- O_2)$, were identified in a group of lines obtained by Geuter in the region λ4600–6000, and have been identified with a number of faint solar lines. The identification seems to be unmistakable.

I have thus obtained two successive members of a Rydberg sequence, and calculated the ionising frequency to be $\nu = 86521$, corresponding to a voltage of 10·68 volts. The ionisation potential of phosphorus is thus found to be slightly higher than that of sulphur, the element succeeding it in the periodic table. We have a similar case in nitrogen and oxygen.

The investigation thus establishes the presence of phosphorus in the sun.

An Optical Method for Analysing Photographs of α-Ray Tracks.

MR. L. F. CURTISS, writing in NATURE of April 6, describes a method for examining stereoscopic photographs of α-ray tracks taken by two cameras at right angles. The method which we have been using for some years for the measurement of the lengths and initial directions of emission of β-ray tracks (originally suggested to us by Prof. C. T. R. Wilson) depends on the same essential principle as that described by Mr. Curtiss, and our experience confirms his observation of its accuracy and convenience. We described the method in a paper on "The Ranges of Secondary β-rays" (*Phil. Mag.*, 2, p. 1110, 1926) as follows: "The lengths of the tracks were obtained from the stereoscopic photographs by replacing the photographic plates in the cameras, illuminating them and tracing out the common image which coincides in space with the original track." We have also used the same method in an examination of the initial directions of emission of photoelectron tracks (*Proc. Roy. Soc.*, A, 121, p. 612, 1928). In the case of observations with β-rays, since the track is not in one plane, the use of the translucent screen (as described by Mr. Curtiss for α-rays) is not applicable.

In our experiments the axes of the two cameras were not at right angles, but were inclined at a small angle of about 20°. With this arrangement it is possible to *see* the track in stereoscopic relief, if, instead of holding a screen in front of the camera, we look through one lens with the right eye and through the other lens with the left eye. In actual practice this greatly facilitates the measurement of the tracks. A fuller account of the method will shortly be published elsewhere.

Geotropism and Antennæ.

I HAVE just been listening to a discussion, at the Zoological Laboratory, arising from some interesting observations by Mr. G. L. Clarke on the tropisms of *Daphnia*. A question was asked as to the conceivable mechanism of geotropism in an animal very little heavier than water and with no air bladder, and an expert in crustacean appendages suggested that, as the animal slowly sinks, fine sensory hairs on the appendages are bent upwards.

It has since occurred to me that, when passively extended, *Daphnia's* two swimming antennæ, branched and set with long fern-like bristles, will offer relatively great resistance to movement downwards through the water, a resistance on a long lever which must be met on the short internal arm of the lever by at least ten times the force in the muscle or ligament involved.

The actual stimulus for geotropy (positive or negative) might therefore be either an increase in tone of the lower muscles of the antennæ, or a decrease in tone of the upper muscles. If this hypothesis be considered plausible, we have an explanation why nauplii and copepods have evolved these two disproportionately long swimming arms, in place of being content with the series of short equal paddles or cilia which suffice for so many other organisms. It is no longer remarkable that the most prominent swimming organ of the larva should be an important sense organ in the adult decapod—for it has always been a sense organ.

Science and the Classics[1]

By Prof D'ARCY WENTWORTH THOMPSON, C B , F R S

IT has been the rule from time immemorial, not the exception, for science and the humanities to go hand in hand Aristotle the naturalist wrote of poetry , Plato was a lover of astronomy , Theophrastus the botanist was a master of rhetoric, whom even Cicero admired , Celsus the physician was an encyclopædic scholar after the taste and fashion of his age When the humanistic tradition was at its height in the ' revival of learning,' Galen and Hippocrates were read by all Linacre the physician helped to bring Greek into England, and was one of the great scholars of his time Moreover our physicians have never lost but have richly inherited and enjoyed the classical tradition , Payne and Greenhill, Osler and Clifford Allbutt in our own time, were scholars after the manner of Haller and Boerhaave and Richard Mead and Sir Thomas Browne Cuvier, busiest of men, wrote a commentary on the natural history books of Pliny Linnaeus himself could write of Nature with a scholar's pen and look upon her with a poet's eyes the severe " Systema Naturae " was the work of one who fell on his knees when he beheld the sunlit gorse at Hampstead, and apostrophised mother Nature in words which sound like the echo of an Orphic hymn " Natura, Filia Dei, rerum omnium Magistra, autodidactos, indesinenter laborans, nunquam festinans," etc

If a man's mind be open to the influences of culture at all, he finds not a little of it within the range of his own profession, even though it be a technical one My own science of zoology looks a very different thing at my age from what it did forty or fifty years ago Around its bare facts have grown the stories and associations which travel, friendship, reading have supplied Loose threads have woven themselves into a web A fact discovered yesterday is balanced by the history of two thousand years Knowledge is no longer something learned in the study, but that is imbibed during one's wanderings through the world , not something which is contained in a book or books, but which in all lands and languages is part of the living speech and daily business of men, part of the common birthright of mankind

The faculty of weaving wider and wider associations around our work and thoughts, and of thus enlarging the horizon of our minds, is helped by that sympathetic attitude and spirit of which a broad education has laid the first foundations But again, the Muses are often kindest to those who have worshipped little at their shrine It is common nowadays for clever schoolboys to spend many hours of every day in a chemical laboratory, from the age (say) of fourteen an age at which we were learning Greek, and Plato's young Athenians were playing on the lute It might be supposed that our young chemists were laying up for themselves what Talleyrand called " une triste vieillesse " By no means So wonderful a thing is a schoolboy, such a piece of work is a man, that our schoolboy-chemists are little the worse of their narrow and eccentric education The learned chemist is still a learned man , in love and knowledge of the arts the chemists are scarcely beaten by the scholars Not a few are steeped in the romantic history of their science, know what is to be known of ancient Greek and Egyptian chemistry, search out the medieval secrets of the poisoner, the alchemist, and the magician, and are versed in the Arabic and other recondite languages in which so many secrets are hid

If it be an attribute or an end of culture to find something which shall take us out of our narrow lives, help us to forget the routine of our employments, and bring us in touch with the wide world, old and new, near and far away, to read history and poetry is a simple and time honoured way , nor is there better history or poetry than that which the dead languages enshrine Men who love these find them very helpful , they enable young men to see visions, they help old men to dream dreams

A few months ago a scholar died, full of years and of honour, in whom science and the classics were very perfectly combined Sir William Thiselton Dyer was the acknowledged head of English botany , as botanist and gardener his influence went out into all lands, to the benefit of mankind, from the garden where he had the happiness to dwell , and all the while he was a true scholar, a Hellenist, acute, fastidious, and profound

Thiselton Dyer learned his Greek and Latin in a London day school , so did I mine in Edinburgh —in that *Schola Nova* of Dunedin where my father had taught R L Stevenson and Andrew Lang and many another , had read the whole Aeneid through with them as beginners, and told them they were the first child mariners who ever circumnavigated that noble poem In seven years at school I never had a lesson in science, nor yet, I believe, had Dyer , but he and his companions, and I and mine, were botanists and naturalists in our teens It was a Golden Age, when there were no scholarships to win, no examiners to satisfy We had freedom to follow our bent, and leisure in which to teach ourselves

If there was one school-book which Thiselton-Dyer loved more than another it was Virgil's " Georgics " Virgil never fails us, nor wearies us, nor does custom stale his infinite variety The schoolboy thinks the " Georgics " an easy book , the old scholar knows it to be hard, finds in it *semper aliquid novi*, and is tantalised and fascinated by its difficulty There is a line near the beginning about the " slow months " of the year, wherein Augustus found his heavenly habitation " Anne novum tardis sidus te mensibus addas ? " Halley the astronomer, coming to Martyn's help, explained the line by the brief statement that " Leo, Virgo, Libra, and Scorpio are really of slower ascension than the other eight signs of the Zodiack , to which Virgil no doubt alluded " But scholars

[1] From the presidential address delivered to the Classical Association, Cardiff, on April 9

have been slow to accept an interpretation which seemed, as it seemed to Heyne, more subtle than poetic, and Conington declares that *tardus* "need be no more than a disparaging epithet, intended to exalt the power of Cæsar, who is to speed the year"! Dr Fotheringham has given me a full explanation, on Halley's lines The 'months' are signs of the zodiac, or the corresponding spaces which the sun travels over in a month Owing to the obliquity of the ecliptic the signs, or the corresponding spaces of 30°, do not rise above the horizon in equal times The calculation is somewhat technical, but the result is, briefly, that in the year 35 B C and the latitude of Naples, the four signs above mentioned took each about 2½ hours to rise, while Aries and Pisces, at the other end of the scale, rose in about an hour and ten minutes In other words, the signs round about the autumnal equinox took more than twice as long to rise as those about the vernal equinox, and the middle of the four 'slow months' lay precisely between Virgo and Libra or 'the Claws',—"Qua locus Erigonen inter, Chelasque sequentes, Panditur"

Dr Fotheringham tells me another fact, which was quite new to me namely, that what looks like, and is generally taken to be, a parallel passage in Manilius has an entirely different meaning "Ne mirere moras, cum Sol adversa per astra Aestivum tardis attollit mensibus annum" This refers to the sun's anomalistic' motion, which is fastest at perihelion and slowest at aphelion, that is to say, in classical times it moved fastest in Capricorn and slowest in Cancer, and 'mensis' here means the monthly course of the sun Now it so happened that the three signs in which the sun moved slowest, Gemini, Cancer and Leo, were precisely those in which (and in which alone) the zodiacal figures were depicted with the head or front towards the east So Manilius frames the conceit that the sun moves slowly because these *astra* are adverse

The naturalist, the botanist, and the astronomer, when they betake themselves to the classics, strive continually to interpret them as generations of their kindred have been doing for five hundred years Now and then a nail is set in a sure place, and the task continually advances, without ever coming to an end Some day, but not yet, Greece herself will help us Only of late has the botanist had a flora of Greece which he can depend upon, we are sadly ignorant of its fauna We long especially for better knowledge of its vernacular names of beast and bird and plant and creeping thing, such as are proving of deep interest to the naturalist and the scholar in the multitudinous dialects of Italy

The humblest task of the naturalist is the identification of species, but, both in biology and the classics, it lies at the root of the whole matter If we do not know the flower of which a poet sings, we blur the outline of his picture and miss his most delicate allusions You remember, in the "Oedipus Coloneus", how the clustering flowers of the narcissus, *ὁ καλλιβότρυς νάρκισσος*, spring up under the dew of heaven, and make the *μεγαλαῖν θεαῖν ἀρχαῖον στεφάνωμα*—the time honoured garland of the Magnae Deae My brother of our Greek chair brought me the passage only the other day, to ask me what flower *νάρκισσος* was, I told him (to begin with) that it was a *narcissus*, which is to say, a daffodil But we may read, in the "Hymn to Demeter", how Proserpine was gathering narcissuses, when she, poor maid, "by gloomy Dis was gathered" I thought she had her little foot on the unbending corn, and poppies in her hair! How came she to be picking daffodils, when the autumn was come, and she must be stolen away and leave her earth mother desolate and forlorn? The simple, pretty explanation is that we may find a tiny, late flowering daffodil, Virgil's "sera comantem narcissum", growing in Greece and Italy, on the dry hills where there is no moisture but the dew, it flowers with the autumn crocus, Sophocles' *χρυσαυγὴς κρόκος*, and lasts until winter comes Proserpine picked it with the last rose of summer and the crocuses, for her farewell nosegay, she took it down with her to Pluto's realm, and men call it her *ἀρχαῖον στεφάνωμα*

Our daffodils have little or no perfume But the old fifteenth century traveller Busbequius, the same who brought the Constantinople Dioscorides to Vienna (which Sibthorpe went to Vienna to see), found our little autumn daffodil 'miro odore fragrantem" When Proserpine picked her daffodil nosegay, such a fragrant incense smell went up that Heaven and earth and sea all laughed for joy

> *κηώδει δ' ὀδμῇ πᾶς τ' οὐρανὸς εὐρὺς ὕπερθε*
> *γαῖά τε πᾶσ' ἐγέλασσε, καὶ ἁλμυρὸν οἶδμα θαλάσσης*

We miss something, if we say that narcissus means a daffodil—and pass on!

One of my father's colleagues in Ireland was J F Davis, who edited the "Eumenides", he was a very learned but eccentric man Going home on one of my undergraduate vacations from Cambridge, I met Davis in a Galway street, who cried out from afar off—it was his only greeting "*Can* you tell me what plant Pliny's *Cassia* really was?" It happened that a German scholar had lately declared "Quid Cassiae nomine veteres appellarint, nunquam divinabimur" Now when Virgil and Ovid speak of cassia, along with thyme and rosemary, they mean marjoram, and it is so depicted in the Vienna Dioscorides Martial's *Cassia*, which was burnt for incense on a funeral pyre, was the Semitic name of a sort of cinnamon, brought home from India by the spice merchants Early commentators mix up the poisonous Italian spurge-laurel (a sort of *Daphne*) with both of these, and Pliny mentions them, all three If I had known as much as this fifty years ago, I might have given Davis a partial answer to his question But Pliny also mentions a kindred spice or drug, an evil-smelling spikenard from the Ganges, which he calls *Ozaenitis* a word which one would never doubt came from *ὄζειν*, 'to smell', if one did not know that so obvious a *Volksetymologie* was almost certain to be untrue This strange name and substance Thiselton-Dyer has ingeniously explained

If we enlarge our knowledge of ancient geography by the help of Greek and Arab geographers, we may

follow, with delight and wonderment, the old trade routes known to Sindbad the Sailor, and to Solomon the King The Periplus of the Red Sea leads us by one of these straight to the ancient city of Ozene, an entrepôt of the spice merchants It has changed neither its name nor its commerce, it is the rich city of Ujjain, in Gwalior, the busy centre of the Indian opium trade Dyer had the acumen to detect that *Ozaenitis* was spikenard from Ozene just as in Dioscorides, *Mossulitis* was *Cassia* from Mossylon, the ancient haven hard by Cape Guardafui where the spice merchants landed their costly bales —the 'aromaticae species quas mittit Eous"

When Carlyle was old he wished they had taught him the constellations when he was young, and "made him at home in the starry heavens" and I too wish I had learned as a child to read the picture book of the sky It is an infinitely noble and exalted theme It was the first art which grew into a science in the hands and minds of men Some say it gave mankind a first glimpse of the divine, by man's soul and by the stars of heaven Sextus the Mathematician declares that Aristotle found his way to God and it is written that the firmament showeth his handiwork The Greeks covered the sky with fairy tales—'fabulis Graii complevere caelum,' said Martianus Capella and Quintilian declares that no man can understand the poets if he be ignorant of astronomy— nec si rationem siderum ignoret, poetas intelliget"

On the threshold of this delightful study we are met by the cardinal fact that the panorama of the heavens is continually but very slowly changing so that the heavens of which Aratus tells are not our heavens, and Homer's pictures of the sky, though they are exquisitely true, are no longer to be seen by mortal men For the heavens have their Great Year, in which each month of the twelve is 2000 years long, and a single day is threescore years and ten Some hold this to be the true theme of the Fourth Eclogue The Great Year, the Old Year, is drawing to its close when 'Ultima Cumaei venit iam carminis aetas", and anon, when 'incipient magni procedere menses", the Great Year begins anew The Great Year and the precession of the equinoxes by which it is explained are doubly and trebly interesting to the classical scholar Its discovery is commonly attributed to Hipparchus, and constitutes his title to immortality, this is a crucial argument of those who hold that the Greek genius was alone capable of transmuting crude barbarian knowledge into true science and wisdom But the Assyriologists have lately found that this palmary discovery was made, at least essentially, two hundred years before Hipparchus, by Kidinnu, Pliny's Kidenas, of Sippur in Chaldea, and the Babylonian astronomer has his place henceforth among the greatest of men

Ulysses leaned on his long oar and watched the Pleiad and Bootes and the Bear—Boötes who sets so tardily, and the Bear who turns and turns about, and glares upon Orion, and never dips his feet in Ocean's stream But we who know that the Bear never sets in our northern sky, are surprised to find him setting like other stars, and by no means ἄμμορος ὠκεανοῖο λοετρῶν, when we go to the Mediterranean or the Aegean It is many a day of the Great Year since the Bears went dry shod over the Aegean, but to tell just when they last did so is a simple matter, in the art or science of astronomical chronology The Bear was ἄμμορος λοετρῶν ὠκεανοιο in the Mediterranean about 800 or 900 B C, and for some centuries before Homer tells us that on the night in question Boötes, Orion, and the Pleiad were all visible together and we may take it for granted that they formed a notable configuration the place and season of which men were accustomed to observe Ulysses was *navigating* by the stars but why mention so many stars for such a simple thing? We glance nowadays up at the sky find the Pointers and follow them to the Pole star in a moment But in Ulysses time there was no pole star nor had there been one for hundreds of years!

Greek mariners steered by the Great Bear, and Tyrians by the Little Bear, but both alike were makeshifts for neither Bear stood at the pole and neither could stand still Only in some particular position would either of them give the true north, and that position must be defined by other stars Suppose Ulysses out a sailing one October night, about a thousand years before the coming of our Lord a little before the dawn he saw Arcturus and the Pleiad, balancing one another as it were, one hanging above the eastern horizon the other over the west Down in the south west Orion was shining, the Bear was watching him with his two bright eyes just then these two eyes (which we call the Pointers) lay one to one side and one to the other of the meridian and the Bear himself, body and tail, stretched away into the north east from this meridian line Ulysses looked at the Pointers and knew he was facing to the north, he then kept the Bear on his left hand, in the position in which *it then was*, and so steered to the south west He was on his course to Scheria

The distinction between science and the classics vanishes away when we come to history archaeology, or folklore, wherein the object of our study is mankind Andrew Lang and a few others began to show us a generation ago, how there was a science in the homeliest words and things and the spirit of history in a game, an incantation, or a toy In the 'Pharmaceutria" of Theocritus we used to think the magic bird and magic wheel mere witchcraft, superstition, moonstruck madness—nothing more Then came Andrew Lang and the others, to show the wealth of meaning in these unconsidered things We have learned that the wheel still hums in the little hands of a Sicilian child, and that a kindred wheel roars its dull note in the hidden rites of the Australian bush It thundered in the horrid feasts of Cretan Zagreus, it sounded amidst the roll of drums, as in darkest Africa, for Rhea and Bendys and Cotytto Jason had it of Aphrodite, to bewitch Medea The Sicilian calls it a cicada, the Greeks knew it by a bird's name All the Orphic mysteries, and who knows what more out of the dark religions of the

East lie behind the story of the girl who sat under the Lady Moon a singing Turn wheel turn and fetch my own lad home to me

When my father was writing of the dead languages a dead civilisation had been but recently revealed the chance directed efforts of a traveller had shown the world that Nineveh and Babylon were seats of tranquil learning and treasured science before ever a fleet had sailed from Aulis or the eagles had promised empire to the watcher on the green Palatine More than once since then has discovery repeated herself raised up the ghost of empires which had gone down into the pit and called from sepulchral palaces the long procession of the dead To learn what Greece had of her science her religion her mysticism her genius her language and her blood from the civilisations by which her own was encompassed and preceded is to my mind the greatest puzzle of history the noblest problem for the scholar Were I a younger man I should want above all things to know Egyptian Assyrian and Hittite and all the rest of that pre Hellenic apparatus of the scholar which the last century has half revealed I have been dreaming all my life of the riches of this Promised Land a few grapes have been brought me from Eshcol—but I am come no farther than Mount Abarim

When the wind blows from Assyria it brings not only odours but also stray whispers to our ears We remember how in the comedy of the Birds the two Athenians who pass by the hoopoe s dwelling on their way to the building of Cloud Cuckoo Town come laden with basket earthen pot and myrtle twigs

> Trudging along with basket pot and myrtle
> To find some quiet easy going spot
> Where we may settle down and dwell in peace

The scholiast with the ignorance of his kind explains this paraphernalia as so many useful implements for scaring away the birds But now we learn that in an Assyrian text from the library of King Assurbanipal precisely these three things a box (or basket) an earthen pot and a myrtle spray are named in the self same order as sacred utensils to be used in connexion with *the founding of a city* Such is the ray of light thrown by modern archæology on a single and apparently insignificant line

Caput inter nubila condit — her head is muffled from our sight —was said of antiquity as also of fame and scholarship like science has her secrets to discover and her mysteries to explore

Whether we be taught science or the classics in our boyhood is not the last word of all B it which ever of the twain it be let us so learn it as to love it and so love it that we may love it to the end

α δ ἂν μαθῃ τις τα τα σ ζεσθα φ λε πρ ς γ ρ ς

Science and the classics The one says (in Wisdom s words) They that eat of me shall yet be hungry And the other says They that drink of me shall yet be thirsty And both alike continually enlarge our curiosity and multiply our inlets to happiness

---

The South Africa Meeting of the International Geological Congress

THE High Court of geological opinion met for the first time in 1878 at Paris with a membership of 310 Since that year there have been thirteen meetings held at intervals of three years or so at various capitals or other centres in Europe as well as in North and Central America the long interval of nine years which separated the twelfth meeting in Canada during 1913 from the thirteenth session at Brussels in 1922 was due to the War and its aftermath

The present century is witnessing a remarkable extension—in theory and practice—of the principle of internationalism in many branches of human endeavour of this the pages of NATURE afford ample evidence For the geologist extensive travelling is indispensable and this is reflected in the steady growth in the number of those attending the sessions of the Congress the record gathering of 742 geologists representing some forty different nationalities is a striking testimony of the extent to which world co operation has grown in this science

For its fifteenth session the Congress meets during the last week of July and during August of this year in South Africa at the invitation of the Government of the Union with its headquarters at Pretoria The practical support from the Government as well as from the mining industry at Johannesburg and Kimberley from municipalities and other public bodies and from various generous friends has made it possible to arrange an attractive programme This is the first occasion on which the Geological Congress has met in the southern hemisphere and the exceptional opportunities which South Africa offers for the study of many fundamental problems of geology will make a strong appeal throughout the geological world Though the Union of South Africa is not yet known with a degree of detail comparable with that reached in some older countries where geological investigation—both official and private—has been carried on for much longer periods enough has been accomplished to allow one important function of the Congress—the examination of the outstanding geological features of South Africa—to be carried out with profit and interest to the visiting members Unfortunately the great distances involved make heavy demands on the geologist s time and purse but the efforts of the organising committee have met with a considerable measure of success so that substantial concessions have been granted by the steamship lines and the South African railway administration

The first main object of the Congress—to take stock of recent advances in geology—has in accordance with the excellent practice established at previous meetings enabled certain subjects to be placed in the foreground of the discussions The

important results that this excellent policy promises may be illustrated in the classic symposium on the origin of crystalline schists which makes the *Comptes rendus* of the London Congress in 1888 such a valuable record to the student of rock genesis Almost all the special topics set down for the meeting in South Africa clearly reflect several of the particular features in which the geology of that country deserves the special attention of the Congress Magmatic differentiation pre Pleistocene glacial periods the Karroo System its stratigraphy palæontology and world distribution to these rift valleys the genesis of petroleum and the geological work of micro organisms have been added by special request

Probably nowhere in the world are the phenomena of magmatic differentiation more superbly displayed in extensive outcrops than in the unique igneous complex of the Bushveld a petrographical province covering more than 16 000 square miles of country and including rocks that range from granite through norite and various ultrabasic types to massive segregations of almost pure magnetite and chromite frequently alternating with bands of that remarkable group—the anorthosite Needless to say this almost inexhaustible field of study long ago attracted the attention of the South African geologists—of whom Molengraaff State geologist of the former South African Republic was the first to recognise the genetic connexion between various members of the Complex By 1922 the more systematic survey of the Bushveld had advanced sufficiently to induce Prof R A Daly to organise a Shaler Memorial Expedition to South Africa with the special object (amongst others) of examining what Daly and Molengraaff describe as the largest and most remarkable igneous complex yet mapped

South African geological literature has been enriched by two most valuable contributions from the members of this expedition in the first Prof Daly and Prof Molengraaff discuss the structural features of the Bushveld Complex (*Journal of Geology* 1924) while in the second (*Bull Geol Soc of America* 1928) Daly gives a brilliant analysis of the petrographical and chemical aspects revealed by the major phases of the Complex The long excursion after this summer s session of the Congress specially devoted to the Bushveld follows closely the route traversed by Daly and his friends and the membership already secured promises not only valuable and profitable results but certainly also a stimulating experience for the South African geologists concerned It need scarcely be said that the curious occurrences of primary deposits of platinum for which the Complex is gradually assuming great economic importance including those strange and unique vertical tubes of dunite are not to be overlooked on this excursion

Since the days when Sutherland in 1868 first recognised the glacial origin of what is now firmly established as the Dwyka conglomerate the study of pre Pleistocene glacial periods has made great strides both in South Africa and in the other continents where Permo Carboniferous glaciation is in evidence and a special excursion will give a glimpse of the stupendous glacial activity which has left us with the remains of ground moraine spread over more than 17 000 square miles and demonstrate the superb striated floor etc of this Dwyka conglomerate for which the Kimberley neighbourhood has become so justly famous that one might call that region the glacial geologists National Park

Apart from the Permo Carboniferous South African geologists have recognised four other pre Pleistocene glacial periods all of which are older than the Dwyka In this recognition the late Geological Commission of the Cape of Good Hope has taken the principal part One of these can be traced in the glacial conglomerate of the Table Mountain sandstone of the Cape System in the Cape Peninsula etc Another is found in the Lower Witwatersrand System in the Heidelberg area while a third is reflected by the tillite in the Griquatown Series of the Transvaal System (N W Cape and Central Transvaal) The fourth period is that of the Numees Series in Namaqualand An examination of the majority of these glacial deposits is included in the programme of excursions and no doubt will furnish much material for interesting and helpful discussion

No apology is needed for selecting for discussion at a meeting in South Africa the stratigraphy palæontology and world distribution of the Karroo System which is *par excellence* in that sub continent covering approximately one half of the Union of South Africa with its rich reptilian fauna and instructive fossil flora with which geologists have become familiar through the researches of Broom Haughton Du Toit and others It is to be hoped that the palæontologists will not miss examining the exceptionally fine type collections of Karroo fossils which form a recognised feature of importance in the South African Museum at Cape Town The Karroo stratigraphy etc (including the profuse sills of dolerite) with some of its organic remains will receive special attention on the Cape Kimberley Port Elizabeth and Durban Zululand excursions the first named also covering good fossil localities of the (Devonian) Bokkeveld Series of the Cape System

A discussion on rift valleys is most appropriate to the venue of this Congress it is obviously a branch of tectonic geology of far more than local interest and its inclusion by special request on the part of those closely identified with this line of research is to be welcomed—no less than the offer by one of the latter to invite a symposium on this subject by means of an illustrated lecture

For the second main object of the Congress—a study of the geology of the country visited—the organising committee has evidently felt—and we cordially endorse its view—that in a country relatively so little known to geologists outside South Africa a large and varied series of excursions would make a special appeal and a study of the programme shows that in this respect the fifteenth Congress should certainly constitute a record since the twenty two excursions extend from Cape Town in the south northwards to Elizabethville in the

Congo, and from Lüderitzbucht on the Atlantic to Durban on the Indian Ocean, forming a network of journeys that cover an area one third the size of Europe! Yet this comprehensive programme is so skilfully worked out that every member has an opportunity of taking part in a large proportion of the excursions These range from half a day to twelve days—and they study not only the taste but also the purse, while their scientific success should be assured when one glances at the names of the leaders Among the outstanding geological features to be visited are the Victoria Falls (with their fascinating physiographical history), the Bushveld Complex, the Karroo, the Great Eastern Escarpment of the Drakensberg at the Devil's Kantoor (the magnificent scenery of which has made this a classical spot for studying the tremendous physiographic contrast in the relationship between the Central Plateau and the coastal belt), the Zululand Cretaceous Beds, and the unique Vredefort Dome, where a central granite is surrounded by a girdle of sediments showing an inversion of the succession through thousands of feet of thickness, and associated with an almost incredibly intense metamorphism Through the published work of Molengraaff, Hall, and Nel, much detailed information on these extraordinary phenomena is available Of the various occurrences of alkali rocks, the programme provides a visit to the Franspoort bodies near Pretoria, the alkali granites and canadites round the Vredefort Dome, as well as the Pilandsberg (with its remarkable ring inclusions)—the largest alkali mass yet examined in detail, which has recently been described by Shand (*Transactions of the Geological Society of South Africa*, 1928)

Economic geology naturally has a prominent place in the programme the Kimberlite diamond pipes of Kimberley and the Premier Diamond Mine (whence came the largest diamond on record), the Witwatersrand with the world's most important goldfields, the primary platinum deposits of the Bushveld, the remarkably rich asbestos mines near Barberton, the rare chromite occurrences in the Bushveld Complex, the ore deposits and peculiar desert geology of South West Africa, including the mineralogists' well known hunting ground of the Tsumeb lead and zinc mines, and last, though certainly not least, the copper bearing regions of Northern Rhodesia, now recognised as a most important asset in the mineral resources of the British Empire

The Congress has also begun the practice of setting aside for special study the world's resources in certain types of ores—for example, iron, coal, pyrites—and the resulting volumes remain a handsome testimony to the foresight of the Congress No happier choice could have been made for the South Africa meeting than the subject of the "Gold Resources of the World"

The recent publication by the Geological Survey of the Union of a map on the scale of one in a million, also the latest volume (written by some members of that Survey) in the well known series of the "Handbuch der regionalen Geologie", dealing specifically with the Union, will be much appreciated by visiting geologists in particular For those who may want to take in a wider field there is the admirable volume by Du Toit on "The Geology of South Africa"

The almost simultaneous meeting in South Africa of the British Association, under the presidency of a distinguished geologist, Sir Thomas Holland and the useful measure of co operation with the Congress, arranged for at Johannesburg and Pretoria will render 1929 a memorable year in the history of geology, while the gathering of the world's geological clans in that sub continent may well repeat the truth of the well known phrase "Ex Africa semper aliquid novi" A L H

Obituary

THE MAHARAJ RANA OF JHALAWAR

THE announcement in NATURE of April 20 of the death of the Maharaj Rana Bhawani Singh of Jhalawar while again on his way to Europe recalls the fact that, of those with whom he was associated in previous visits, too many would not have been here to welcome him He would doubtless have missed especially Sir James Dewar at the Royal Institution, Prof A D Waller at the Physiological Laboratory in the top story of the University of London, Sir Archibald Geikie, president of the Royal Society at its 250th anniversary, which the Maharaj Rana attended as a delegate from India, and besides those, Miss K Stephen, principal of Newnham, in 1912, and the presidents of the meetings of the British Association, Sir William Herdman at Cardiff in 1920, Sir Edward Thorpe at Edinburgh in 1921

The Maharaj Rana's first visit to Europe in 1904 furnished material for a book of travel pictures, published in 1912, when he came to England for a long stay with a suite of court officials in attendance, among whom, the Pandit Shyam Shankar was indefatigable in providing opportunities for the acquirement of knowledge of the West and the diffusion of knowledge of the ways and customs of the East

Meteorology was one of the sciences that caught the Maharaj Rana's attention He became a familiar figure at meetings of the International Commissions for Maritime Meteorology and for Weather Telegraphy which were held in London in September of that year It was an interesting time, because telegrams from Iceland, wireless telegrams from ships, and an international code for gale warnings were on the agenda papers The Maharaj Rana acknowledged the courtesy of the Commissions by a stately dinner, at which, with other novelties, the members with their ladies were initiated in the parting ceremonies of garlands and attar of roses

A visit to Cambridge in the same year provided the experience of luncheon and the gardens at Newnham College, with an exchange of civilities

between potentate and student by the aid of hand cameras then dinner in a college hall and the cultured serenity of the combination room, so impressive as to suggest that two or three years at an English university would form the proper completion of the education of the heir to a throne In 1920 that idea found expression at Oxford Kumar Rajendra Singh, recently married to the daughter of the Maharaja of Vizianagram, went to Christ Church, and the Maharaj Rana enrolled himself at New College Apart from a short return home in 1921, he lived in Oxford for two years, but he was always to be found at the lectures of the Royal Institution The British Association, the Royal Sanitary Institute, the Royal Aeronautical Society, and again, whatever was going on at the Meteorological Office, engaged his attention, including another meeting of the International Commission for Weather Telegraphy His part in the many scientific meetings which he attended was mainly to listen and appreciate Conversation was favoured as a mode of expressing himself, rather than writing or speechmaking, in that and in his letters he was invariably alert and precise

The *Times* of April 15 gave a striking account of the character and achievements of the Maharaj Rana as a ruler Others will cherish the remembrance of a genial and enthusiastic student of Nature and art As a Rajput his traditions and reminiscences were of military prowess and achievements with the bow As one condoles with the new Maharajah on the loss of his father, it is impossible not to wonder what would happen if the Indian princes betook themselves to the conquest of the secrets of the Nature that surrounds them, if they should turn their swords into tuning-forks and their arrows into sounding balloons NAPIER SHAW

SWEDISH zoology has sustained a serious loss in the death of Prof Nils Johan Teodor Odhner, which occurred at Stockholm on Oct 29, 1928 Prof Odhner was born at Lund in 1879 Graduating at the University of Uppsala, he became lecturer in zoology at that University In 1914 he was nominated as professor of zoology in the University of Oslo (Norway), and four years later he became *Intendant* of the department of invertebrates in the State Museum of Natural History in Stockholm Prof Odhner's zoological work consists principally of systematic and faunistic papers on the Trematoda, upon which group of animals he had been for many years a leading authority He also devoted some time to the study of certain groups of Crustacea His activities were not, however, confined to zoological research His wide social interests and energetic contribution to the intellectual life of his country are manifested by the various official positions which he occupied—as a delegate to the League of Nations, president of the Sweden Finland Foundation, and vice-secretary of the Swedish Academy of Science As a speaker and writer he contributed much to the popularisation of his own branch of science

WE regret to announce the following deaths

The Right Hon the Earl of Rosebery and Midlothian, K G, K T, F R S, Chancellor of the University of London, who was elected to the Royal Society in 1886 under Statute 12, which permits of the election of persons who "either have rendered conspicuous service to the cause of science, or are such that their election would be of signal benefit to the Society", on May 21, aged eighty two years

M Emile Chaix, professor of physical geography at the University of Geneva, aged seventy four years

News and Views

THE most important legislation affecting the welfare of migratory birds, since the Migratory Bird Treaty Act of 1918 between the United States and Canada, was passed by the U S Senate on Feb 11, and signed by President Coolidge on Feb 18 This was the Norbeck Andresen Migratory Bird Conservation Act, which has been fought for eight years in eight sessions of Congress, and finally succeeded when the matter of a Federal license, to which objection had been taken, was omitted from the Bill The Act is a direct sequel to the Migratory Bird Treaty of 1918, for it was found that, useful as that Treaty had been, much of its potential value seemed likely to be lost if provision could not be made for a system of refuges or sanctuaries in the areas traversed by the birds in their migratory flights, and on their wintering grounds The purchases of such reserve areas demanded large sums of money, and it was to meet this outlay that the Federal license, which proved to be the stumbling-block of the original Bill, was proposed The difficulty of finance has been removed by proposed State grants Although the Act makes no appropriation, it authorises a schedule of appropriations amounting in all to some eight million dollars, and settling down after ten years to an annual sum of 200,000 dollars The first year's sum of 75,000 dollars is to be devoted to a survey of the area to determine the places best suited to become bird refuges, and, this completed, the selected areas will be purchased and henceforth guarded by an appropriate staff The American Game Protective Association, which has strongly advocated the proposals of the bill in its bulletin, *American Game*, is to be congratulated on the success of its campaign

A SPECIAL type of rubber made by the Expanded Rubber Co, Ltd, Wembley Park, and marketed under the trade name of 'Onazote', which appears to have many uses in science and technology, has recently been mentioned in the Press Onazote is essentially a very spongy form of rubber prepared by vulcanisation under high gaseous pressure, which is sometimes as high as a hundred atmospheres During the cooling process the pressure is gradually reduced, with the result that the occluded gas expands, forming pockets of air enclosed in thin rubber membranes Onazote can be prepared with a variety of physical properties by suitably varying the process of preparation In particular, it can be produced in a hard

form not unlike ebonite in external appearance, and in a soft pliable form In each case the fine cellular structure is of course retained

THE material has a remarkably low specific gravity of the order 0 076 to 0 102 (that is, it weighs 4½ 5 lb per cubic foot), and the hard variety is stated to be practically impermeable to water The soft form combines low density with high resiliency, and tests indicate that after the removal of the compressing load the sheets return practically at once to their initial thickness As may be conjectured from its physical nature, onazote has a very low thermal conductivity The value of this constant as measured on a sample at the National Physical Laboratory is 0 00008 gram calories per square centimetre per second for 1 cm thickness and 1° C difference in temperature between faces It is suggested that the material may have a variety of uses Its lightness and non absorbent properties render it suitable for life belts and floats, and its resiliency suggests its possibilities in making shock absorbers, cushions, and allied articles It is also claimed to be of use as a sound absorber for making silence cabinets and improving the acoustics of buildings The hard variety has electrical properties akin to ebonite but without the brittleness of ebonite

THE problem of distributing the white population of the British Commonwealth in the most efficient manner as between all its parts, is the object of the various schemes of Empire settlement which are included in the Report of the Oversea Settlement Committee for 1928 (London H M Stationery Office, Cmd 3308) Among the many problems on which the report touches is that of the checks on this desirable redistribution of population These are many, and include, in Great Britain, the industrial habits and townward bent of the population and its unfitness and unwillingness to settle on the land, the upward tendency of the standard of living, the effect of schemes of social insurance which tend to anchor population and decrease its mobility, and the fact that the spirit of emigration becomes evident when the population is prospering and not in times of adversity In the Dominions, there are also certain factors that check the flow of population from the home country The call for population does not necessarily bear relation to the conditions in Great Britain and the need for emigration The Dominions want mainly agricultural workers and, among women, domestic workers, while the need for emigration is chiefly among the industrial workers The growing tendency of all the Dominions to make a more and more vigorous scrutiny, in the interests of racial fitness, of all who wish to enter the territory, reduces further the flow of emigrants from Great Britain

THE first conversazione this year of the Royal Society was held on May 15 in the Society's rooms at Burlington House As usual, there were numerous exhibits and demonstrations representing recent developments in many branches of science, as well as instruments and photographs of historic interest Atomic physics does not easily lend itself to large scale demonstration, but Prof G P Thomson showed photographs from his work on the diffraction of electron waves, and Messrs Adam Hilger, Ltd, included in their exhibit one of Dr Jean Thibaud's X ray grating spectrographs for soft X rays Applied physics exhibits included an instantaneous visual direct reading radiogoniometer (Radio Research Station, Slough) Physiological apparatus included a moving iron oscillograph recording sensory nerve action currents (Mr Bryan Matthews), and a portable electrocardiograph (Cambridge Instrument Co, Ltd) Recent biological work was represented by exhibits of 'breaking' in tulips from the John Innes Horticultural Institution, plants toxic to insects (Rothamsted Experimental Stations), and several exhibits from the British Museum (Natural History) Prof W A Bone and Mr R P Fraser showed some remarkable photographs of flame propagation in gases, Sir Robert Hadfield specimens of various special steels, the Anglo Persian Oil Co an apparatus for the visual examination of oil being cracked under pressure, and so on Twice during the evening Dr R G Canti gave a kinematograph demonstration, consisting of consecutive series of photomicrographs, of living tissue cultivated *in vitro* The film showed the processes of cell growth in the normal and malignant tissue out wandering of fibroblasts and wandering cells, the various stages of cell division including migration of the chromosomes, cell degeneration, phagocytosis The last part of the film, which dealt with the fibroblast of the chick embryo under dark ground illumination, showed the internal structures of the cell

AT the Friday evening meeting of the Royal Institution on May 10, Prof A E Boycott gave a fascinating account of the genetics of the mode of twist of the shell in *Limnæa peregra*, and illustrative collections were also on view at the Royal Society soirée on May 15 In the majority of species of snails the twist of the spiral is dextral, but in a few it is normally sinistral In many of the normal dextral species sinistral varieties occur, and vice versa, and these unusual forms occur either as odd sporadic specimens or else as an established component of the population *Limnæa peregra* is normally dextral, and its sinistral variety is very rare—less than a dozen sporadic having been recorded In four ponds in England the population of dextral snails included a small proportion (5 per cent or less) of sinistrals Four of these sinistral individuals were used for experimental breeding work It was found that sinistrality is a simple Mendelian recessive which is inherited according to the usual plan, save that any change of twist imposed by crossing is delayed for one generation The snail inherits not its own twist but the twist of its offspring, and segregation is by broods and not by individuals All inheritance in *Limnæa* is, however, not maternal Albinism was found to be a simple Mendelian recessive, transmitted in a straightforward fashion Sinistrality and dextrality are characters of considerable importance, for the reason that in the Helices, which are incapable of self-fertilisation, copulation is impossible between the two forms The peculiar inheritance of shell twist

is due to the fact that this character is determined at the first division of the egg, soon after the entrance of the sperm, and the form of the division is determined by the constitution of the egg and the sperm does not effect it Albinism, on the other hand, is a character which is not expressed until much later in development, by which time the contribution of the sperm has become effective

The speech delivered recently by Sir Robert Hadfield, as chairman of Hadfield's, Ltd, contained many points of special importance and showed the advances which the steel firms of Great Britain, including his own, are making In connexion with the attempts now being made to foster a better spirit between employers and employed, it is of special interest to note that, so long ago as 1894, Sir Robert presided at a well attended meeting of employers and labour representatives in London, when a body was formed to which the name of the Industrial Union of Employers and Employed was given The body had objects in view of a similar nature to those now being formulated by the Melchett Turner conference, and met with strong approval from many men of a more far seeing character Sir Robert remarks that, Had the employers at that time taken the matter with the same heartiness, and given the same support rendered by the labour representatives to myself (the president) and the Council, I fully believe that this work would not have come to an untimely end and would have proved of great national benefit I believe that the organisation then proposed would have gradually grown in importance and that much of the trouble since experienced might have been largely avoided "

In speaking of scientific research in Great Britain generally, and especially of research with a possible technical bearing, Sir Robert Hadfield made the following important observation "It is most advisable that research work should be fostered in the various universities of Great Britain Whilst we all recognise the splendid work done by the National Physical Laboratory, which is an exceedingly important organisation, those local centres must not be overlooked when monetary grants are being allocated It is usually the local centres which best know the needs of the particular locality concerned There is no reason why subventions or grants, whether from Government headquarters in London or locally, should not be freely handed over to our various local universities, thus locally stimulating and encouraging research, which is more than ever important nowadays" Interesting remarks were also made concerning the growth of the induction melting of metals and the new heat resisting steels The advance made in the latter connexion is indicated by the example given of a steel heated to a temperature of 1200° C for 21 hours which, after that very drastic treatment, was scarcely scaled at all

On Tuesday, May 14, the Prince of Wales formally opened the North East Coast Exhibition at Newcastle upon Tyne This great industrial exhibition, representative of the life and work of the north of England, has been organised and built in less than two years on a commanding slope on the Town Moor, and will remain open until October Prominent features are the Palaces of Engineering and Industries, where the Tyneside manufacturers have made good use of the opportunity of showing the manifold activities of the industrialist corner of England The Prince of Wales, who went to the Exhibition after opening the new department for mining research at Armstrong College, congratulated the promoters on the general lay out, its aim, he said, "is to revitalise existing industries, to discover how they should be adapted, and, if necessary, improved" Scientific discovery linked with industry is well represented in the president of the Exhibition, Sir Charles Parsons, and it is in this direction that we must look for the adaptations and improvements visualised by the Prince of Wales and for new methods and new industries to enable the British Empire to maintain its place in the world's markets

The Federation of Lancashire and Cheshire Museums, founded in January 1928, has issued a first annual report, which summarises very briefly the aims and accomplishments of the Federation The object is the practical one of a more efficient museum service as between museums themselves and as between museums and the public, and the experiment will be watched with keen interest in the hope that it may contribute to the solution of the difficulties and staleness of the smaller local museums The means adopted have been periodical meetings of museum curators and members of their committees, where subjects of practical interest are discussed, and a scheme for the donation, exchange, or loan of specimens between the federated museums Twenty three, out of a possible of thirty eight museums in the two counties, have joined the federation, the meetings were reasonably well attended, and the exchange scheme has been made use of by thirteen museums There can be no doubt about the excellence of the federation idea, time will decide whether the museums themselves are enthusiastic enough and energetic enough to make it a success

The Imperial Bureau of Soil Science, one of the eight Bureaux the formation of which was recommended by the Imperial Agricultural Research Conference of 1927, commenced work on May 1 at the Rothamsted Experimental Station Sir John Russell, Director of Rothamsted, is also the Director of the Bureau, and Dr A F Joseph, lately Sudan Government Chemist, has been appointed deputy director The functions of the Bureau include the collection and distribution of all research work of importance on soils to the British Empire, the assistance of research workers in the prosecution of their investigations in whatever ways it can, the bringing together of workers from different parts of the Empire (either by correspondence or in conference) interested in the same subjects, and to supply information generally which may facilitate the work of soil experts in the development of agriculture It is hoped that before long the Bureau will be in close touch with all soil investigators

of the Empire, both at home and abroad, and that by means of information circulars and other methods, the results of studies carried on in one part of the Empire will be made available for all. Arrangements will also be made to supply information dealing with soil investigations in foreign countries, the results of which, owing to language or other difficulties, are not readily available.

The Bohemian Academy of Sciences has recently issued its *Bulletin International* for 1926, containing in its 628 pages résumés in English or French of the papers communicated to the Academy during that year. These communications number nearly fifty, and cover the whole field of mathematical and natural sciences and medicine, and many, especially those dealing with biology, are illustrated with photomicrographs and other well executed illustrations. This is particularly noticeable in the three coloured plates accompanying Dr. V. Breindl's studies of plasmodium, those with Dr. J. Wolf's investigation of the genesis of collagen fibres, and those of Prof. B. Němec and Dr. Milovidov on bacteria in plant and human tumours. There is a posthumous contribution from Prof. J. V. Daneš on the limestone physiography of the United States of America, and among a number of other geological papers are several by Dr. Petrbok on the stratigraphy of the Palestine palæolithic (the first containing 108 figures). In mathematics, Dr. V. Trkal has given a contribution to the dynamics of the neutral helium atom whilst the *Bulletin* also contains Dr. Sobotka's deductions of certain polar properties in conic systems. Chemical science is represented by papers on the radioactivity of potassium and rubidium (Miss Petrova), adsorption by colloidal carbon (Dr. Podronžek), the electrolytic estimation of bismuth (A. Jílek and J. Lukas), and a study of the pyrrolones (R. Lukeš).

The only railway line laid across South America is the one joining Valparaiso and Buenos Aires, traversing both Chile and Argentina. It provides an overland connexion 840 miles long between the Pacific and Atlantic Oceans. It skirts the extinct volcano of Aconcagua in the Andes, and its maximum altitude is about 10,500 feet. The section of the railway from Los Andes to Mendoza is called the Transandine Railway. It is laid for a combined rack and adhesion service and has a metre gauge. The operation of this railway was rendered very difficult in winter by snowfalls, often 20 feet deep, and by avalanches of rocks. This necessitated extensive protective works and galleries. Owing to the soft coal used, thorough ventilation of the galleries was also necessary. This, and the fact that the coal used had to be raised to an altitude of nearly two miles against gravity, induced the directors of the Transandine Railway, which belongs to a British company, to adopt electric traction. This enabled an increase in the speed and weight of the trains to be made. As the freight consists mainly of cattle from Argentina to Chile, and perishable fruit in the opposite direction, the increase in weight and speed has many advantages. A full technical account of this railway is begun in the *Brown Boveri Review* for April. This company, in conjunction with the Swiss Locomotive and Machine Works at Winterthur, constructed the combined rack and adhesion locomotives which are used. These are the largest locomotives of this type that have ever been built. The brakes required for these locomotives are quite as important as the driving gear. The brakes for the adhesion driving wheels are of the Westinghouse compressed air type. When the emergency rack brake is used the automatic brakes on both locomotive and train are applied simultaneously. The braking force on the rack sections at the wheel tread is 32 tons. The total continual electrical braking capacity is 456 horse power.

Many accessions illustrating the historical development of the sciences were made to the Lewis Evans collection of the Old Ashmolean during the past year. They include a valuable series of perpetual calendars in various materials, a set of bronze facsimiles of previously unknown surgical instruments used in Pompeii in the first century, several important microscopes from the Crisp collection, and a refracting telescope of great historic interest, namely, the instrument used by the greatest of Oxford's astronomers, James Bradley, who himself lectured in the Old Ashmolean from 1729 onwards. The fifth Annual Report, for 1928, in addition to recording other gifts, directs attention to the need for treating the outer stonework of the building, which has not been refaced since 1679, and mentions a feature of the year which should be of great advantage to the development of the collections, namely, the foundation of a Society of the Friends of the Old Ashmolean. Previous to the annual meeting of this Society on May 4, Prof. D'Arcy W. Thompson delivered a public address on "The Hellenic Element in the Development of Science", to which reference was made in our issue of May 11, p. 732.

The annual visitation of the Royal Observatory, Greenwich, will take place on Saturday, June 1.

At the anniversary meeting of the Royal Society of South Africa, held on Mar. 20, the following officers for 1929 were elected:—*President*, Dr. W. A. Jolly; *Hon. Treasurer*, Dr. L. Crawford; and *Hon. Secretary*, Dr. B. F. J. Schonland.

The Council of the Royal Meteorological Society has sent a message of congratulation and good wishes to the Society's honorary member, Prof. Hugo Hergesell, on the occasion of his seventieth birthday, which will occur on May 29. We understand that addresses of congratulation will be presented to the veteran director of the Lindenberg Observatory by learned societies and official bodies in Germany in recognition of his services to meteorological science and its application to aviation.

An International, Colonial, and Maritime Exhibition is to be held in Antwerp next year in celebration of the Treaty of Belgian Independence. The British Empire will be well represented and the Treasury has sanctioned an expenditure of £100,000 on the exhibit

The most important British shipping companies are to have displays in the British section, and manufacturers of equipment for ships, such as navigation instruments, etc, will be specially invited to exhibit

AN International Photography Exhibition, to be held at Gothenburg on Oct 15–31, is being organised by the *Goteborgs Handels och Sjofarts Tidning* No entrance fees and no charges for return of exhibits are made A special section of the Exhibition will be devoted to scientific photography Correspondence concerning this section should be addressed to Dr S E Ohlon The honorary secretary of the Exhibition is G F Ahlberg, International Photography Exhibition, Box 52, Gothenburg, Sweden

TOWARDS the end of last year a British committee representative of some twenty six engineering institutions and technical societies was formed to organise a party of British engineers to attend the World Engineering Congress to be held at Tokyo on Oct 29–Nov 22 and to secure papers for presentation at the Congress (NATURE, Jan 12, p 62) Seventy six papers have now been contributed dealing with railway and river engineering, strength of materials alloy steels, aircraft, petroleum technology, chemical engineering, coal cleaning town planning, illumination and photometry, etc It is anticipated that a party of thirty five to forty representatives of British engineering theory and practice will attend the Congress

THE Council of the Institution of Electrical Engineers has made the following awards of premiums for papers read during the session 1928–29, or accepted for publication The Institution Premium to Mr Johnstone Wright and Mr C W Marshall Ayrton Premium to Mr L G H Sarsfield, Fahie Premium to Mr A E Foster, Mr P G Ledger, and Dr A Rosen, John Hopkinson Premium to The Hon Sir Charles Parsons and Mr J Rosen, Kelvin Premium to Mr E B Wedmore, Mr W B Whitney, and Mr C E R Bruce, Paris Premium to Mr J L Carr, Extra Premiums to Capt J G Hines, Mr B L Goodlet, Mr L H L Badham, and Mr W Phœnix, Wireless Premiums to Mr T L Eckersley, Capt P P Eckersley, and Mr A B Howe, Mr R M Wilmotte and J S M'Petrie

AN expedition for the study of the behaviour of the mountain gorillas of Belgian Congo is announced in a recent *Daily News Bulletin* issued by Science Service, Washington, D C The expedition has been undertaken jointly by Yale University and the Carnegie Institution of Washington, by special arrangement with the Belgian government Dr Harold C Bingham of Yale, a psychologist who has already carried out extensive studies on the behaviour of apes in captivity, will be the scientific representative of the two American institutions He hopes to establish close and sustained contact with groups of mountain gorillas, to follow their movements day and night, and to observe their traits of behaviour in relation to species and varieties, their manner of life, and their distribution The expedition will leave the United States in June and proceed by way of Dar es Salaam to the head of Lake Kivu, whence a trek of a hundred miles will take the explorers into the gorilla country

THE fortieth Congress of the Royal Sanitary Institute is to be held at Sheffield on July 13–20, under the presidency of the Right Hon Earl Fitzwilliam, who will deliver the inaugural address on Monday, July 15 Sir Allan Powell, chairman of the Food Council, will deliver the Congress lecture, taking as his subject, "Some Aspects of the Food Problem", and Prof W W Jameson will deliver a popular lecture 750 delegates have been appointed by 430 authorities in the British Empire and other countries Among the subjects arranged for discussion are mental hygiene of the child and of the adult, health education, food hygiene, industrial welfare, smoke abatement, housing and regional planning, rivers pollution, and water supply The Right Hon the Lord Mayor of Sheffield, Alderman Harry Bolton, is the chairman of the local committee, and the Town Clerk, Sir William Hart, and the Medical Officer of Health, Prof F E Wynne are joint honorary local secretaries

APPLICATIONS are invited for the following appointments on or before the dates mentioned —A head master of the Junior Technical Evening Institute, Shelburne Road, Holloway The Education Officer (T 7), County Hall Westminster Bridge S E 1 (May 29) A teacher of building subjects at the Municipal Technical School, The Gamble Institute, St Helens—The Secretary for Education, 17 Cotham Street, St Helens (May 30) An assistant lecturer in electrical engineering at the Bradford Technical College—The Principal, Technical College, Bradford (May 31) A full time teacher in the Mechanical Engineering Department of the Lincoln Technical College—The Principal, Technical College, Lincoln (May 31) Temporary posts under the Department of Agriculture for Scotland, namely, two investigators and an indoor assistant for work in connexion with an inquiry into marketing live stock and other agricultural produce in Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (June 1) A woman resident lecturer in geography and mathematics at the Bangor Normal College—The Principal, Normal College, Bangor, North Wales (June 3) An assistant lecturer in the Mathematics and Physics Department, The Polytechnic, Regent Street — The Director of Education, The Polytechnic, Regent Street, W 1 (June 3) A lecturer in mathematics and a lecturer in physics at the University College of Swansea—The Registrar, University College, Singleton Park, Swansea (June 5) A principal of Brierley Hill Technical Institute, Stafford—The Director of Education, County Education Offices, Stafford (June 5) Research chemists at establishments of the Department of Scientific and Industrial Research—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S W 1 (June 6) A junior assistant (engineer) at the Fuel Research Station, East Greenwich—The Secretary, Department of Scientific and Industrial

Research, 16 Old Queen Street, S W 1 (June 6) A headmaster of the Junior Technical School, Ashton under Lyne—The Education Office, 8 Warrington Street, Ashton under Lyne (June 8) Clothworkers' Research Scholarship in the Department of Textile Industries, the University, Leeds—The Clerk to the Senate, The University, Leeds (June 8) A lecturer in metallurgy and assaying at the Manchester Municipal College of Technology—The Registrar, Municipal College of Technology, Manchester (June 13) A lecturer in physics at Christ Church, Oxford—The Very Rev the Dean, Christ Church, Oxford (June 14) A lecturer and demonstrator in the department of physics of the Royal Holloway College—The Principal, Royal Holloway College, Englefield Green, Surrey (June 15) A lecturer in engineering and practical mathematics in University College, Dundee—The Secretary and Registrar, The University, St Andrews (June 15) Civilian education officers in the Royal Air Force Educational Service—The Secretary, Air Ministry, Gwydyr House, Whitehall, S W A junior assistant in the department of the War Department Chemist—The War Department Chemist, B 47 Royal Arsenal, Woolwich S E 18 A chief field officer of the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee, Rubber Research Institute of Malaya, 2 Idol Lane, E C 3 A lecturer in mathematics at the Gordon College, Khartoum—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S W 1 (marked "Mathematics") Junior research assistants under the British Cotton Research Association—The Director, British Cotton Research Association, Shirley Institute, Didsbury, Manchester

Our Astronomical Column.

SOLAR STREAMS OF CORPUSCLES AND MAGNETIC STORMS —Prof S Chapman discusses the motion of streams of corpuscles from the sun in *Mon Not Roy Ast Soc* for March He uses Prof A E Milne's result that the Doppler effect will enable upward moving atoms to climb out of the absorption lines associated with them, and to be accelerated away from the sun The acceleration diminishes as the distance increases, so that for the greater part of the journey to the earth's orbit the motion is nearly uniform The time occupied is between one and two days, agreeing with the lag often observed after the passage of a spot over the central meridian of the sun before the arrival of the storm It is explained that, while individual atoms are moving nearly radially, the stream as a whole is rotating with the sun and so overtakes the earth, magnetic storms therefore begin near the sunset meridian of the earth It is estimated that the breadth of a stream when crossing the earth's orbit is of the order of 50 earth radii, in which case it would take twenty five minutes to sweep over the earth

The difficulty of explaining how the corpuscles can penetrate so deeply into the earth's atmosphere as to give rise to low level auroræ is dealt with The suggestion that these auroræ may arise from induced currents due to the corpuscles at higher levels is considered not to account for the definite forms of the auroral rays, it is thought more likely that the extrapolation used to obtain the resistance of air at extremely low density is at fault

FALL OF METEORITES INTO STARS —The presence of certain wide diffuse absorption bands which are well marked in the spectra of some stars, especially those of early type, was recently attributed by Dr H Shapley and Miss C H Payne to meteoric matter near the stars Later research, however, modified this view, and the glass of prisms or lenses was regarded as a more probable origin for these bands The latter conclusion is supported by theoretical considerations published by Prof H N Russell in the *Astrophysical Journal*, vol 69, p 49 It is shown that all meteorites (except abnormally large ones, more than 1 foot in diameter) will be completely volatilised before reaching the surface of the sun or a star The gas thus produced will scatter an amount of light dependent on the ratio of radiation pressure to gravity, and in this way might account for a small fraction of the coronal luminosity The total quantity of meteoric matter falling into the sun, however, cannot exceed 60 tons per second, and the maximum effective absorption produced (when radiation pressure nearly equals gravity) is not sufficient to produce the equivalent of a single narrow Fraunhofer line It is concluded that meteoric matter cannot account for perceptible bands in the spectrum of any star which is not surrounded by extremely dense nebulosity

THE SPIRAL NEBULÆ —New methods of study of the spiral nebulæ are being evolved with great rapidity at Mt Wilson The March issue of the *Proc U S Nat Acad Sci* contains papers by Dr E P Hubble and Milton L Humason, in which the radial velocities are studied and found to constitute a new criterion of distance Results for some of the brighter spirals had been obtained at Flagstaff many years earlier, and it was then found that there was a general tendency to motion of recession With the 100 inch reflector it has been possible to extend the research to fainter objects, and there is now sufficient material to apply statistical methods

It was found that those nebulæ which on other grounds were considered more remote gave larger motions of recession than those concluded to be nearer A solution was then made of the sun's motion with respect to the system of spiral nebulæ in which a K term was applied (the term being derived from that used for the systematic outward movement indicated by stars of our own galaxy), this was assumed to be proportional to the distance of the object The solution gave for the sun's apex the point R A 277°, N Decl 36°, velocity 280 km /sec, and K 500 km /sec per million parsecs Once this K term has been established, it can be used as a rough measure of the distance of remote nebulæ The largest recessional motion so far detected is that of N G C 7619, one of a small cluster of nebulæ on the border line between Pegasus and Pisces This is receding with a speed of 3779 km /sec, which becomes 3910 when corrected for the solar motion found above The distance estimated from the speed is 25 million light years, which is in good accord with the estimates from diameter and brightness

It is pointed out that, in de Sitter's cosmology, distant objects would show a recession increasing with remoteness, this is ascribed both to an apparent slowing down of atomic vibrations and to a general tendency of material particles to scatter, Dr Hubble expresses the hope that observations extended to more distant objects may make it possible to evaluate the amount due to each cause

Research Items

Modern Views on Life.—A reasonably stated view of the modern conception of life, by Prof. F. G. Donnan, appears in the May number of *Scientia* under the title "The Phenomena of Life". He points out that physiological investigation has shown much of the freedom and spontaneity of life to be more apparent than real. The living being neither destroys nor creates energy; it obeys the physical law of the conservation of energy. Nor is a living thing a magical source of free energy or spontaneous action; its life and activity are ruled and controlled by the amount of free energy in its immediate environment, and it lives and acts by virtue of this; that is to say, it obeys the so-called second law of thermodynamics. Yet there is more than this in life; the unit of living matter, the cell, builds up a whole which is greater than its parts. Whether the understanding of the specific finalistic manifestations of this whole will be explained on present day hypotheses or may demand the hypothesis of some new form of energy, the understanding will ultimately consist in something that permits of exact measurement and of precise expression in mathematical form, even though for the latter purpose a new form of mathematics may have to be invented.

Early Culture in Texas, U.S.A.—A recent examination of objects found in caves in the vicinity of El Paso, of which the importance lies in the indication of future lines of research rather than in actual results, is reported by Mr. F. H. H. Roberts, jun., in No. 7 of vol. 81 of the *Smithsonian Miscellaneous Collections*. Mr. Roberts first visited the caves some years ago while investigating the pictographs of the area, including those of the far-famed Hueco Tanks, an oasis, once a rendezvous of wandering bands of Apaches and travellers across the desert. Afterwards a large number of 'curios' were unearthed in the caves by two residents of El Paso. These, together with further finds from undisturbed portions of the caves, have been examined by Mr. Roberts in a recent visit. The pictographs in the caves belong to the group in the south-west to be attributed to the Apache, though a few of the older show Pueblo influence. Three of the figures are masked heads, and stepped structures on two of these may represent a framework similar to those of which actual fragments were found in the caves. The stepped form is comparable to Pueblo forms. Birds and snakes are readily recognisable, whether naturalistic or conventionalised. Among the objects of special significance found are woven sandals of fibre, spear shafts, curved clubs, a basket armlet with a crude setting of turquoise chips, abalone shell pendants, beads and a few fragments of pottery. The sandals are of a characteristically south-western type. The spear shafts, which are made of the flower stem of the agave, are coloured red and decorated with balls and streamers of agave fibre. Attached to them are small rods, similar to those found elsewhere, but the significance of which is unknown. The curved clubs are comparable to those of the Basket Makers' caves of north-east Arizona and south-eastern Utah. While it is clear that there is here an admixture of early and late, these objects indicate affinities with the Basket Makers, and it is suggested that the culture of the caves is the northern fringe of the Basket Makers culture of San Juan.

Curious Function of Gums in a Porpoise.—The remarkably small size of the teeth in the porpoises of the genus *Phocænoides* is well known. Gerrit S. Miller, having examined well-preserved specimens of the Alaskan species, *P. dalli*, is of opinion that the teeth are practically functionless and that their use as organs capable of grasping food has been taken by a curious development of the gums (*Proc. U.S. Nat. Mus.*, vol. 74, 1929). The gums are modified so as to form a set of secondary gum teeth, alternating with and surrounding the true teeth, which have come to lie at the bottoms of pits between the bases of the new structures, the size and hardness of which is such that they are undoubtedly capable of functioning as efficient grasping organs. The general condition shown in this toothed cetacean is similar to that of the early stages of development of the baleen plates of the whalebone whale *Sibbaldus*, where the true teeth have disappeared and gum teeth, compressed along the axis of the jaw, and increased in height, have formed. The resemblances are so important that the author considers that the gum and dental structures of the Alaskan porpoise represent stages of development closely parallel to those through which the corresponding parts in the toothed ancestors of the whalebone whales must have passed.

Encystment and Conjugation in *Pleurotricha*.—Reginald D. Manwell (*Biol. Bull.*, 54, 1928) describes encystment and conjugation in the hypotrichous ciliate *Pleurotricha lanceolata*, which has two macronuclei and two micronuclei. Encystment may occur at any time and appears to have no relation to periods of depression, to division, or to conjugation. Both macronuclei are extruded and only one micronucleus remains. It is uncertain whether the other micronucleus is always extruded or whether the remaining micronucleus is produced by the fusion of the two original micronuclei. From this one micronucleus the new nuclear apparatus is reconstituted, the process being complete by the time the ciliate is ready to leave the cyst. In conjugation there are three maturation divisions, an interchange of pronuclei and two, or rarely three, cleavage divisions. Of the four products of the second cleavage division one soon enlarges and gives rise to the new macronuclei of the ex-conjugant, one of the other products degenerates, and the remaining two form the new micronuclei. Reduction occurs in the second maturation division, the haploid number of chromosomes being probably twenty. "Conjugation appears to be not only an unnecessary part of the life cycle, at least as long as environmental conditions remain favourable, but is a very dangerous event, for 92 per cent of one hundred exconjugants died without further division, and only one per cent showed any indication of an accelerated fission rate," "and even in this case the daughter race died within a month."

Bitter Pit Disease.—Some recent investigations on the apple disease known as bitter pit, with practical information as to the chief means by which it may be avoided, are described by W. M. Carne in *Australian Journal for Scientific and Industrial Research*, vol. 1, No. 6. The disease came into prominence in Australia about 1900, and since 1911 has received the serious attentions of many scientific workers. Carne has now been able to elucidate the problem to a large extent. Picking tests with a number of varieties showed that bitter pit develops chiefly, if not entirely, in stored fruit and is thus quite distinct from cork, another disease previously known as bitter pit, but which develops on apples while on the tree. True bitter pit disease is caused by picking the fruit before it is sufficiently mature, large fruit being more susceptible than small. Although if picking is postponed too long the danger of over-ripeness during

storage is incurred, some greater delay than has been usual hitherto in the picking of apples for export will be beneficial, as not only will the liability of the fruit to bitter pit be reduced, but also a high quality in flavour and appearance will be ensured The correct date for picking can best be ascertained by means of the iodine method devised by Bigelow, Gore and Howard in 1905 The amount of starch in the apples as shown by the iodine reaction is definitely related to the amount of bitter pit disease, colour, and flavour afterwards developed after storage The method of testing consists in dipping cut halves of freshly picked apples into an iodine solution (potassium iodide 1 gm, iodine 0·25 gm per 100 c c water) for half a minute After a short exposure to the air the distribution of the blue colour is noted If the colour is almost or entirely absent the fruit is over mature for picking, but if scattered in small spots throughout the pulp outside the core line, the fruit can be picked with safety On the other hand, large patches of colour in the flesh indicate the necessity for allowing the apples to hang longer With practice other apples of the desired degree of maturity can be selected by eye This procedure assumes that the fruit will be placed in cold storage within a few days from picking

SOLANUM HYBRIDS —An account of crosses between *Solanum utile* and pollen from the domestic potato has been given by Salaman (*Jour Genet*, vol 20 No 3) The cross was only a success in 25 per cent of the 52 attempts, and the reciprocal cross could not be obtained at all Also, as a result of many trials, a single plant, indistinguishable from *S utile*, was obtained by pollination with *S chacoense*, and it bred true in the next generation In the crosses between *S utile* and the domestic potato several cultivated varieties were used as pollen parents, and with three exceptions giving the same result In the F_2 and later generations, whole families were indistinguishable from *S utile* in morphological characters, yet certain physiological and genetic differences can be shown by back crossing such as the presence of sterility and the incidence of disease Some of these families, while showing the low cropping capacity of *S utile*, are nevertheless carrying recessive genes for higher cropping, the inhibitory factors of *S utile* being dominant Other families were nearly, with some plants quite, indistinguishable from the domestic type The inheritance of the differences in leaf characters and cropping are particularly described

LEPTOCHILUS AND GENERA CONFUSED WITH IT — Following the modern tendency in taxonomy to seek a phylogenetic arrangement for all groups of plants, E B Copeland (*Philippine Journal of Science*, vol 37, No 4, December 1928) has published a revision of the African, Indian and Oriental species of the genus *Leptochilus* Six natural groups, each given generic status, are recognised *Leptochilus* is retained as a small genus of epiphytic ferns, the largest genus, *Campium*, consisting of terrestrial ferns with creeping rhizomes This genus receives monographic treatment, fifty six species—eighteen of which are newly described—being enumerated The study of the whole group is complicated owing to the involved nomenclature, and much attention is devoted to the determination of the proper generic and specific names The paper contains a large number of text figures showing details of frond venation in the species of *Campium*, and all new species and a number of old ones are illustrated by plates

CONIFERÆ —The identification of Conifers by means of their vegetative organs is the subject of an interesting paper which appeared recently in the *Scientific Proceedings of the Royal Dublin Society* (vol 19, N S 19) The author, Mr H M FitzPatrick, having in mind the difficulties that beset systematists when flowers and fruit are not available, has compiled a key to the genera and species of the Coniferæ, based on the morphology of the foliage There are certain difficulties inseparable from such an attempt, not the least of these being the diversity of foliage in juvenile and adult forms of the same species The nonconformity to type of recent introductions to cultivation, particularly species of *Abies* and *Picea*, create further complications Such a scheme of classification, to fulfil its purpose, must of necessity be an artificial one This does not detract, however, from its value for diagnostic purposes and in its construction Mr FitzPatrick has achieved a considerable measure of success Leaf shape and arrangement form the basis of the key to the genera, while its subdivisions rest on the prominence, or otherwise, of stomatal bands and midrib the woody nature of the second year twigs serve to distinguish the Abietineæ and Taxodium from all other Conifers For the recognition of species special keys are introduced, following, more or less, conventional lines In this connexion the use of variable features, pubescence for example, as specific indicators, though sanctioned by custom is open to question The ultimate definition of the species is materially assisted by a series of brief descriptions of their individual characteristics, supplemented by numerous illustrations, some of which, however, are unfortunately lacking in precision Notes on their economic uses and distribution form a useful adjunct to descriptions of the species The paper concludes with a short bibliography

GEOLOGICAL MAP OF MONT BLANC —A geological map of the French part of the massif of Mont Blanc is being issued by Paul Corbin and Nicolas Oulianoff on the scale of 1/20 000 The first sheet (Servoz les Houches) appeared in 1927 The second (Chamonix) and third (Les Tines) sheets have now been issued, and each is accompanied by a descriptive pamphlet (Imprimerie Librairie G Jacquart Price 20 francs) A general and detailed geological description of the massif is promised in due course The maps measure nearly 14 × 10 inches plus borders and legends, and the geological units and topographical base are clearly printed with excellent registration The Quaternary deposits are coloured in clear pale tints the older formations being given more vigorous colours so that they stand out clearly The lithological composition of the crystalline rocks is indicated by overprintings of points and lines on the fundamental colours In this way the major tectonic units are well brought out as well as the individual formations, sedimentary or igneous The maps may be recommended not only to professional geologists but also to those who may be holiday making in the Chamonix district and wish to know something of the rocks that are there displayed

THOLEIITES OF THE NORTH OF ENGLAND —Continuing their work on the igneous geology of the north of England, Prof Arthur Holmes and Dr H F Harwood have recently published a detailed account of the Tertiary tholeiite dykes (*Mineralogical Magazine*, March 1929, pp 1 52) Eight new chemical analyses are presented, and in addition to the Brunton, Talaidh, and Salen types already recognised by the Survey petrologists, Cleveland and Acklington types are distinguished, these referring typically to the rocks of the dykes well known under those names Although the whole suite of dykes appears to converge to a focus in Arran, it is shown that there is a regional

change of direction, as the suite traverses the Southern Uplands which carries it by way of Great Cumbrae and the Ayrshire coast into the Mull swarm of dykes Many of the dykes carry anorthite aggregates, and Teall's original hypothesis to explain their presence is supported A discussion of magmatic variation leads to the conclusion that differentiation by crystal lisation and separation of the residual liquors was not the process responsible for the production of the different types of tholeiites It is suggested that the variation may have been due to admixture with a Whin Sill type of magma of a quartz alkali felspar eutectic formed from sial by long continued contact with basaltic magma This is a return to a long despised conception first introduced by Bunsen to explain the igneous rocks of Iceland

Measurement of Nile Discharge Over a period of more than twenty years, observations have been made with the view of the establishment of an automatic and accurate measure of the discharge of the Nile throughout the year The last of four papers dealing with this subject is now published in Physical Depart ment Paper No 24 of the Ministry of Public Works Egypt in which Mr D A F Watt gives the final conclusions on the methods and the tables of results It has been found that during the low stage of the Nile there is no significant difference between the results given by sluice measurements at Aswan and current meters but that in flood time the current meters give results about five per cent too high or even more at the top of high floods Experiments with scale models which were described in a previous paper have been shown to be a useful means of inter polating results between the low stage and the floods when the discharge of the sluices is not known with the same certainty as at other times of the year The important conclusion is that the dis charge of the Nile at Aswan can now be measured with a high degree of accuracy by the means em ployed]

North Staffordshire Coalfields — The Depart ment of Scientific and Industrial Research has just issued as *Paper* No 14 of the physical and chemical survey of the national coal resources a description of the coalfields of North Staffordshire (London H M Stationery Office) This paper differs, and differs most unfortunately, from previous ones in the series inasmuch as the special work which the Fuel Research Division of the Department of Scientific and Industrial Research is specifically supposed to perform, namely, the physical and chemical investigation of the coals of Great Britain, is entirely absent from the present paper It contains merely a description of the North Staffordshire coalfield, such as is already obtainable elsewhere Indeed, it carries our information no further, if so far, as do the *Memoirs* of the Geological Survey It would surely have been better to wait until the physical and chemical investigation, which the Fuel Research Division is supposed to undertake, had been completed and then to publish this informa tion in the way that has been done in the case of the other coalfields, rather than to adopt this piecemeal method of issuing information, which, although it may at first sight lead to an appearance of great activity on the part of the Fuel Research Division, really shows that the proper work of that Division is not being pushed as it should be

Hall Effect in Nickel Steel Alloys —Interest attaches to the Hall effect as exhibited by the nickel steel alloys, since the rotations of the two components of these alloys are of opposite sign, and since, moreover, such alloys present peculiarities in their thermal and electrical conductivities which, according to the electron theory, are intimately connected with the Hall effect In the issue of the *Rendiconti* of the Naples Academy of Physical and Mathematical Sciences for May–August 1928, Dr Umberto Salerno communicates the results of measurements of this effect made with a series of steel nickel alloys contain ing different proportions of nickel The Hall effect observed exhibits the same characteristics as that of the ferro magnetic metals, and is influenced to some extent by the nature of the secondary electrodes em ployed The alloy known as invar shows a moderately high coefficient of rotation In all the alloys ex amined asymmetry is revealed, this being most marked with the alloy containing 22 per cent of nickel, which is the least magnetic and almost zero with that having 49 per cent, which is highly magnetic The contribu tion of the steel to the Hall effect is more pronounced than that of the nickel 80 per cent of which is necessary to cause reversal of the sign The variation of the effect with the composition presents analogies with the corresponding variations of the specific heat, thermo electric properties thermal conductivity and electrical resistance

The Triple Point of Water —The usual specifica tion of the zero of the centigrade scale of temperature in terms of the melting point of ice, although very con venient for most purposes, is somewhat unsatisfactory because of the difficulty of reproducing exactly the standard conditions of measurement In particular, the effect of the air which dissolves in the water used is a little uncertain and the German Physikalisch Technischen Reichsanstalt has therefore had under consideration the advisability of replacing the present fixed point by the slightly higher triple point of water A report of the experimental work that has been done in this connexion has been published by H Moser in a recent issue (No 3) of the *Annalen der Physik* It has been found that the temperature recorded by a platinum resistance thermometer can be held constant to one ten thousandth of a degree when it is controlled by a bath containing pure ice, water, and water vapour in thermal equilibrium Subsidiary measurements established that the freezing point was lowered by 0 0074° C from this when the ice was in contact with air free water at a pressure of one atmosphere, so that with an allowance of a further 0 0024° C for the lowering of the freezing point when the water is allowed to dissolve air to equilibrium, in accordance with the Reichsanstalt specification of the zero point, the temperature of the triple point becomes + 0 0098° C The triple point of water is at the present time the most nearly constant fixed point of the temperature scale

Analysis of Phosphoric Acid —A detailed study of the determination of phosphoric acid as magnesium pyrophosphate is described by M Ishibashi in the *Memoirs of the College of Science, Kyoto*, vol 12, No 1 The effects of the composition of the magnesia mixture used, of the acidity of the solution, and of the presence of various salts and acids, were examined, and the conditions for maximum accuracy determined A method was developed for the quantitative pre cipitation of phosphoric acid as manganous ammonium phosphate, the formation of manganous acid being prevented by the addition of a small quantity of hydroxylamine hydrochloride The manganese in manganous ammonium phosphate can be exactly titrated with potassium permanganate In a third paper, a new gravimetric method is described for determining phosphoric acid as zinc pyrophosphate, and in this case the zinc may be titrated by an oxalate method

The New Department of Zoology of the University of Edinburgh

FOR many years past the accommodation in the Department of Zoology at Edinburgh has been inadequate to meet modern needs and to cope with the number of students studying the subject In 1923 the late Mr Laurence Pullar of Bridge of Earn visited the Department and was deeply impressed with the adverse conditions he found Mr Pullar who had long been sympathetically interested in zoology more particularly in those branches of it that occupied the attention of his friend the late Sir John Murray made a donation of £20 000 towards the erection of new laboratories His much appreciated gift remained anonymous until shortly before his death in 1926 In the same year the Trustees of the Carnegie Trust for the Universities of Scotland in their allocation of grants for the quinquennium 1925–30 set aside a sum of £18 000 Prof Augustus Trowbridge of Princeton University then director for Europe of the International Education Board paid an unannounced visit to the Department in 1926 and inquired into its needs and financial position As a result of this and with his sympathetic co operation Prof J H Ashworth was enabled to draw up a statement of the requirements The Board saw its way to give £74 000 for the completion of a building for equipment endowment and addition to staff and technicians

Prof Ashworth drew up sketch plans which were placed in the hands of Sir Robert Lorimer and Mr J Matthew and work was commenced in June 1927 The building was formally opened by H R H Prince George on May 15 last in the presence of the Vice Chancellor a large number of representatives of the national and civic authorities and of zoologists from other universities In his speech Prince George referred to the traditions of the Department the chair of which was founded in 1770 and to the importance of zoology and its many applications to the welfare not only of Great Britain but of the whole Empire The need for trained zoologists, particularly overseas, at the present time is great The building is the second of a new group known by permission as the King s Buildings and Prince George expressed his pleasure at learning that through the munificence of various donors private and corporate other buildings were soon to be erected on the same site forming part of a scheme for the expansion of the University He congratulated the architects upon their success in combining pleasing effect with utility

Photo From Cairds Inglis

FIG 1 —The new Department of Zoology of the University of Edinburgh

After the opening Prince George was invested with the honorary degree of Doctor of Laws made a tour of inspection and attended a luncheon in the Old University buildings The University O T C mounted a guard of honour

The new building (Fig 1) is of sandstone from the Blaxter quarry and consists of a central part with a larger wing facing north and a smaller one facing north east its total length is 287 feet It is two storied for the greater part but the fall of the ground allows of a well lit basement under the east wing Between the large windows in the upper and lower stories are a number of panels with oval medallions about 4 ft 6 in long bearing representations of a series of animals They are arranged in sequence and chosen to represent the main zoogeographical regions They are the work of Miss Phyllis Bone who also furnished for the lintels above the first floor windows smaller round medallions of three animals well known to ancient naturalists the scarab the crab and the octopus

Throughout the whole building the most emphasised feature is the provision of the maximum amount of light The museum which is for teaching purposes

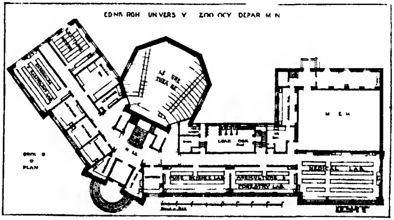

FIG 2 —Plan of ground floor

is 55 feet long by 40 feet wide with a 10 foot gallery along one of its long sides under which is a well equipped aquarium The main museum is lit by a cupola and the gallery by an oblique roof light, and in both is a new type of glass devised by Sir Herbert Jackson in conjunction with Messrs Chance It is designed to exclude the ultra violet and strong actinic rays and at the same time provide a maximum transmission and diffusion of direct sunlight The library is furnished with enamelled steel shelving gallery stair, and stack room and has an initial accommodation of about 8000 volumes, which should

form an adequate reference collection The large lecture theatre, occupying most of the central part is of octagonal form, has a specially constructed diagram screen, and provides 318 separate seats, the two smaller theatres for advanced and post graduate students each accommodate about 50 The laboratories and research rooms on the two wings are laid out as a series of units 15 feet wide by 16 feet deep, and the inclusion of several units gives laboratories of the sizes required for all the different classes The Department has, besides the laboratories for the staff, technicians rooms, workshop, etc, eight separate research rooms each for one worker, and a larger room which would accommodate two to four workers

The total cost of the building has been £80,000, and it is felt that with its modern equipment and design it provides adequate facilities for teaching purposes and for the various lines of research that are now being carried on or are likely to be undertaken for some years to come Two main objects have been kept in the forefront of all the designing, first, fitness for purpose, and secondly, the utilisation of standard units which permit of the maximum amount of interchange and therefore flexibility

Forest Insurance

IN *Special Bulletin* No 179 (September 1928), issued by the Experiment Station of the Michigan State College of Agriculture, Mr Paul A Herbert discusses "Forest Insurance and its application in Michigan The greater part of the author's thesis is devoted to the great forest problem in the United States of fires and fire protection, and the consequent higher rates demanded for insurance on forest property exposed, as is the case in America to this peril Mr Herbert cites the more or less successful efforts at forest insurance attempted in European countries, which had their origin in France and Germany in 1880 Norway in 1912 Finland since the Armistice, in Belgium, Holland Denmark in the late years of last century, and finally in Sweden since 1919

In treating of ordinary insurance as against insurance against forest fires, the author points out as one of the difficulties that annual returns are not obtainable in the younger stages of a forest, and therefore the private owners of land do not consider that forestry can compete with other productive enterprises He rightly concludes that the reluctance of landowners to take up forestry as a business undertaking is based mainly on general questions of the risks, the rate of tree growth, and rough calculations as to future costs and prices It may be admitted that investment in the forestry business will not usually bring in the early returns obtainable from other enterprises, whilst the risks are in some respects greater

The methods often suggested in order to assist the private landowner to make forestry a paying business are more equitable taxation, government assistance, and better protective methods These coupled with an anticipated future increase in the price of timber and other forest produce, would, it is held, make private forestry a paying business These factors would tend to decrease the cost of production or decrease the risk to which the invested capital is exposed

On the subject of taxation of woods, the usual remedy suggested is deferred taxation on lands occupied by woods The chief advantage of this method would lie not in reduced costs, but in reduced risks, and would allow the timber grower to estimate his future taxation in this respect If any accident happened to the crop or impaired its value the taxes would automatically be reduced Government assistance the author considers, should be mainly confined to paying for research work which is beyond the power of the private owner to undertake, whilst the third remedy, protection, involves decreasing the risks and therefore improving the property from an insurance point of view

The keynote of the author's discussion is the reduction of risk by effective protection, thus facilitating insurance of the property Such insurance, by eliminating further risks and losses, will place forestry on a business basis The capitalist', says Mr Herbert, will find the profits obtainable are large enough to be attractive in view of the reduction of uncertainties The investor will consider the insured forest as sufficient security to warrant lending funds to the business at the usual rate of interest" The whole crux of the business in many countries, both in the past and the present, is bound up with the methods in force in land taxation which often do not sufficiently distinguish between land from which an annual return is obtainable and that from which the returns are deferred for long periods, as is the case in forestry

University and Educational Intelligence

CAMBRIDGE —Dr D Stockdale, fellow of King's College, has been appointed University demonstrator in the Department of Chemistry

LONDON —The result of the Convocation elections to the new Senate of the University of London—a general election following the new Statutes—was announced at the meeting of Convocation on May 14 In the Science Faculty there were eleven candidates for five seats, the successful candidates being Dr C W Kimmins with 1018 votes, Prof F G Donnan, 934, Sir Philip Magnus, 889, Dr R H Pickard, 847, and Mr G D Dunkerley, 835 The unsuccessful candidates were Prof Winifred Cullis, 806, Dr G T Morgan, 783, Sir Llewellyn Smith, 544, Mr W A W Dagger, 426, Mr T Ll Humberstone, 354 and Mr A E Evans, 307 In the Arts Faculty the old members were re elected, with the addition of Prof T P Nunn In Engineering, Mr Roger T Smith and in Economics, Dr W H Coates were elected both being new members of the Senate The representatives of faculties include the following — Faculty of Medicine Lord Dawson of Penn, Dr H L Eason, and Sir Cuthbert S Wallace, Faculty of Science Prof A J Allmand, Prof L N G Filon, Dame Helen Gwynne Vaughan, and Prof Frank Horton Faculty of Engineering Prof S M Dixon and Prof E H Lamb, Faculty of Economics (including Commerce and Industry) and Political Science Prof T E G Gregory

MANCHESTER —Applications are invited for the Edmund Mills Harwood memorial scholarship, value £50 per annum for three years, at the Manchester Municipal College of Technology Forms of application and all information are obtainable from the Registrar of the College The latest date for the return of completed forms is June 15

ST ANDREWS —The University Court has appointed Dr Frederick Walker, at present assistant in geology, to be a lecturer in geology as from the beginning of the next academical year

LIKE so many other professions, that of surveying grows more important, complex, and difficult Old rules of thumb and hastily formed opinions can no longer be applied If, among the surveyor's essential

qualifications, mathematics and a wide knowledge of central and local government are added to those divisions and subdivisions of his practical work, it becomes clear that the old method of apprenticeship is quite inadequate Such points were emphasised by Mr B W Adkins in a paper on the education of the young surveyor which he read, on April 8, before a general meeting of the Surveyors' Institution Mr Adkins showed how the system of examinations and other facilities of the Institution have met these changes and made it possible for the profession to be supplied with qualified practitioners Tracing some present weaknesses, he said that if a boy leaves school at sixteen or seventeen and decides to be a surveyor, he finds that he cannot take the intermediate examination for several years During the interim, although serving articles, he frequently loses the habit of study, since he is free from school discipline and has no immediate spur towards theoretical work To meet this difficulty and to ensure continuity of study, the Institution has decided to adopt recommendations which will enable the future surveyor to take the more elementary part of the intermediate examination before the age of nineteen Mr Adkins considered, too, that the recent introduction of a compulsory preliminary examination will remedy other weaknesses such as bad spelling, indifferent English, and lack of accuracy and method Mr Adkins' belief in the work already done by examinations and their future possibility was very definitely expressed "There have been numerous attempts to discredit the examination system I am confident that, if properly devised, a system of examination is the best method of inducing young men to acquire such knowledge as is necessary for their progress"

THE Committee of Award for the Commonwealth Fund Fellowships has made appointments to twenty four fellowships tenable by British graduates in American universities for the two years beginning September next These include Mr Eric Ashby (London) to Chicago, in botany, Mr Geoffrey Crowther (Cambridge) to Yale, in economics, Dr H J Emeleus (London) to Princeton, in chemistry, Miss G H Faulkner (Edinburgh) to Chicago, in zoology, Mr W L S Fleming (Cambridge) to Yale, in geology, Mr V S Forbes (Cambridge) to California, in geology, Mr J N Goodier (Cambridge) to Michigan, in structural engineering, Mr A Harvey (Durham) to California, in physics, Mr R C Hinton (London) to Cornell, in economics, Dr W G Humphrey (Oxford) to Harvard, in chemistry, Mr W R Humphries (Aberdeen) to Columbia, in education, Mr J W Maccoll (Glasgow) to California Institute of Technology, in engineering (aerodynamic), Mr H L Puxley (Oxford) to Yale, in economics, Mr D M Robinson (London) to the Massachusetts Institute of Technology, in electrical engineering, Dr A F Skinner (St Andrews) to Columbia, in education, Mr E T C Spooner (Cambridge) to Harvard, in medicine, Mr A J Watters (St Andrews) to Wisconsin, in organic chemistry, Mr J H C Whitehead (Oxford) to Princeton, in mathematics, and Mr R van de R Woolley (Cambridge) to the California Institute of Technology, in astronomy Fellowships tenable by candidates from the British Dominions include Mr H. Barak (New Zealand and Oxford) to Princeton, in physical chemistry, Mr H. V Warren (British Columbia and Oxford) to the California Institute of Technology, in geology The following have been appointed to fellowships tenable by candidates holding appointments in government service Mr Eric J Bradshaw (Dublin) of the Geological Survey of India, Mr R M Campbell (New Zealand) of the New Zealand Civil Service, Mr A. H Crane (Adelaide) of the Queensland Forestry Service

Calendar of Patent Records

May 26, 1733—The patent granted to John Kay of Bury on May 26, 1733, covered the invention of the fly shuttle, perhaps the most important improvement ever made in the loom It revolutionised the weaving industry and rendered the power loom possible But it left Kay a poor man The last we hear of him is in 1766, when he appeared before a Committee of the Society of Arts, and he must have died soon after, probably in France, where he had tried to obtain the recognition that he failed to get in his own country

May 26, 1798—The principle of the hydraulic ram was first used for raising water by John Whitehurst of Derby, who applied it to a domestic water supply in such a manner that every time the tap was turned on and off in the kitchen, a column of water was forced into a tank in the upper part of the house Whitehurst sent a description of his apparatus to the Royal Society in 1770, but its value as a water raising machine was not recognised until an improved self acting type was invented by Joseph Michel Montgolfier and patented by him in France on May 26, 1798 An English patent was granted in the preceding year to Matthew Boulton acting as Montgolfier's agent

May 29, 1624—The first legislative enactment for regulating the granting of industrial monopolies was the Statute of Monopolies (21 Jac I c 3) passed by the English parliament on May 29, 1624 The Statute was not, as has often been assumed, the foundation of the English patent law, it merely gave parliamentary sanction to principles which had long been accepted at common law Its purpose was to prevent the Crown from granting oppressive monopolies, but in the famous Section 6 it exempted from the general prohibition the granting of patents for the encouragement of new inventions This section is still in force

May 29, 1849—David Smith of New York was granted an English patent on May 29, 1849, for an improved shot tower for making small shot, in which the fused metal falls through an ascending current of air, a process which enabled a much shorter tower to be used

May 31, 1836—There were many inventions before this date for the use of the screw propeller in steam navigation, but credit for its practical introduction is mainly due to Francis Pettit Smith, whose English patent is dated May 31, 1836 Pettit Smith's invention, first tried on a small 10 ton 6 h p vessel which was successfully run on the Thames and afterwards at sea, was, at the request of the Admiralty, fitted to the *Archimedes* of 237 tons and 80 h p, which attained a speed of 10 miles per hour Smith realised little from his invention, but he was given a civil list pension of £200 a year and in 1871 received the honour of knighthood For the last thirteen years of his life he was the curator of the then Patent Office Museum

June 1, 1869—Thomas Alva Edison's first patent was granted in the United States on June 1, 1869, for an electrical apparatus designed "to record and register in an instant and with great accuracy the votes of legislative bodies," each member having a switch in front of him by moving which he could have his name impressed electrically under either the affirmative or negative votes Edison's output of inventions has been enormous, the United States patent records showing that for upwards of forty years patents have been granted to him at the rate of about twenty-five a year, the greatest number in any one year being seventy five in 1882

Societies and Academies

LONDON

Geological Society, April 24.—**Robert Murray-Hughes**: The geology of part of North Western Rhodesia, with petrographical notes by **A. A. Fitch**. The area lies approximately between lat. 14° and 17° S. and long. 24° and 30° E., and falls into three natural divisions, from west to east. The first is the flat, somewhat swampy country overlaid by the Karroo and Kalahari rocks; the second is the old peneplain surface forming the plateau of Northern Rhodesia and underlaid by the Transvaal and Pretoria rocks, and those of the Swaziland System; and the third, a deeply dissected country overlaid mostly by the Swaziland rocks and drained by the Zambezi and Luangwa rivers. The rocks are described and correlated with the Transvaal and Pretoria Systems of the south. The covering of sand in the west, together with certain 'ancient laterites', is correlated with the Kalahari System. The principal structural features are: (1) North-east and south west foliation caused by the intrusion of the Older Granites; (2) north west and south east fracturing caused by the intrusion of the Hook Granite; (3) graben faulting, which forms a part of the Great Rift Valley; (4) folding of the Karroo Beds.

Royal Anthropological Institute, April 30.—**J. H. Driberg**: Gala colonists of the sixteenth century. Analyses the varying incidence of Hamitic influence on the different Bantu tribes of the Lake region. Two immigrant cultures, the first of Gala origin *circa* 1600 to 1680, the second represented by the Bahinda dynasty and possibly referable to Lake Chad. Linguistic and cultural evidence for the Gala hypothesis. That the focus of this Hamitic culture lies to the west of Lake Victoria indicates that the immigrant route was via Mongalla and Wadelai. Traces of Gala influence are to be found among the Lerya, where it is linguistic, and among the Bari, where it is cultural, the present serf class representing the descendants of Gala invaders overthrown by a Bari rising. Nilotic and Nilo Hamitic convulsions due to Gala intervention during the fifteenth and sixteenth centuries, as revealed by a comparison of Nilotic and Bantu genealogies. The southward expansion of the Gala towards the Tana valley, the inception of a militant policy against the Abyssinians, and their colonisation of the cattle breeding countries round Lake Victoria, should all be correlated.

Society of Public Analysts, May 1.—**R. S. Morrell** and **S. Marks**: The determination of organic peroxides. A modification of Fahrion's method of determining the peroxide oxygen in oxidised linseed oil by measuring the iodine liberated from potassium iodide in the presence of sulphuric acid has been devised.—**J. W. Croxford**: Differential halogen absorption of oils and fats. Toms's bromine vapour method of determining the halogen absorption of oils gives rapidly the true iodine value of oils and fatty acids which require very many hours for complete absorption of the Wijs' reagent. Fatty acids and oils of the oleic acid series with the double bond adjoining the carboxyl group may thus be recognised. Iso oleic acids formed in the hydrogenation of oils, and the petroselinic acid of parsley seed oil, give similar results by the two methods, and have thus the double bond at a distance from the carboxyl group.—**W. R. Schoeller** and **C. Jahn**: A new method for the separation of small quantities of tantalum and niobium from titanium. The solution containing the oxalates is treated with sodium salicylate, which converts the titania into a stable crystalloidal sodium titanylsalicylate. The earth acids are then precipitated with calcium chloride, and finally precipitated with tannin.—**H. R. Ambler**: The analysis of small samples of gas. Apparatus for the analysis of small samples of about 1 c.c. of gas, in which rubber connexions are abolished.

DUBLIN

Royal Dublin Society, Mar. 26.—**J. Reilly, P. J. Drumm**, and **C. Boyle**: The production of essential oils from Irish grown plants (Part 5). Oil of dill.—**M. Grimes**: A study of lactose fermenting yeasts found in milk, cream, and butter. The yeasts examined consisted of two types. Type *A*, similar to, or identical with *Torula lactosa*, Harrison, isolated from Canadian cheese; type *B*, similar to, or identical with *Torula cremoris*, Hammer, isolated from yeasty cream.—**J. H. J. Poole** and **A. J. Clarke**: The effect of strong electric and magnetic fields on the rectilinear propagation of gamma rays. Sir J. J. Thomson has suggested that, since electrons show some of the characteristics of very high frequency wave trains, very hard gamma rays may possess some of the properties of charged particles, and he conducted some trials on a possible bending of a gamma ray beam in a dielectric exposed to a large transverse electric field. His results, on the whole, were negative. The present paper describes further trials, not only with electric, but also with strong magnetic fields. No effect in either case could be detected.

EDINBURGH

Royal Society, May 6.—**G. N. Hunter**: Colour sensitivity. In *Proc. Opt. Convention*, 1926, Dr. Houston described a new method of testing for colour blindness. The apparatus was purposely made insensitive by keeping the two colour patches under comparison 8 mm. apart. In the present research, these patches have been brought into juxtaposition, resulting in a great increase in colour sensitivity, estimated at 1000 per cent.—**E. B. Ludlam** and **R. B. Mooney**: The influence of air and moisture on the 'Budde effect' in bromine. The absence of expansion of pure dry bromine when exposed to light is explicable by calculating the rate at which the energy received can be taken up by the walls of the vessel; a film of moisture may prevent the re combination of bromine atoms on the surface and thereby retain the energy in the body of the gas. Air present in the gas may facilitate transfer of energy and cause expansion. There is no evidence of re radiation of energy.—**A. C. Stephen**: Studies on the Scottish marine fauna. The fauna of the sandy and muddy areas of the tidal zone. The density per unit area has been investigated. Parts of the Firth of Clyde (more than 3000 per square metre) and St. Andrews Bay, West Sands, are areas of exceptional abundance. The various species are not uniformly distributed over any beach, but either occur, or have their maximum density at, some particular level. On sandy grounds *Tellina tenuis* and *Nephthys cæca* predominate, on the muddy grounds *Cardium edule* and *Macoma balthica*.—**G. Redington**: Effect of diurnal periodicity on plant growth. By growing plants entirely in electric light, it is shown that a daily dark period is not essential, but with practically all the very diverse species grown, better plants were ultimately produced in 16 hours' light per day than in continuous light. Generally, poor growth was made in a light exposure of 8 hours' daily. The effect of the several physiological processes concerned upon the conditions obtaining at the apical meristem is considered in relation to cell formation and cell elongation.—**Margery Knight**: Studies in the Ectocarpaceæ (2). *Ectocarpus siliculosus*. Plants

collected from the Mediterranean coasts show a simple type of life history in which the plant body is haploid and reproduction is effected by the union of gametes produced in plurilocular sporangia The dominant soma of the British plants is, however, diploid and the zoids from plurilocular sporangia on these plants are already diploid and germinate immediately into new plants, sexual reproduction is achieved by zoids from unilocular sporangia Alternation of generations and sex differentiation are also discussed —**Mary H Latham** Jurassic and Kainozoic corals from Somaliland This collection of fossil corals from British Somaliland was made by Mr R A Farquharson Government Geologist, during his survey of the country in 1923–24 It includes Jurassic, Eocene Oligocene, and one Pleistocene specimen Most of the specimens are Eocene and were collected mainly in eastern Somaliland but some specimens from Deberaweina in western Somaliland have been identified as Eocene That district has not hitherto yielded Eocene corals There are three new species of *Astrocœnia*, all of which have large corallites and greatly resemble *Stephanocœnia*, and a new species of *Cyathocœnia* There is also a new genus, *Tubicora*, belonging to the *Goniocoridæ* The Oligocene corals include new species of *Stylophora Circophyllia*, *Favia Orbicella*, *Columnastræa*, and *Porites* The older faunas have Mediterranean affinities —**Sydney Goldstein** The asymptotic expansion of the characteristic numbers of the Mathieu equation

PARIS

Academy of Sciences, April 15 The president announced the death of M Gayon, *Correspondant* for the Section of Rural Economy —**P Séjourné** The railway from Casablanca to Marrakech The branch line for phosphates This line, 245 km long, was commenced in 1916, the discovery of rich phosphate deposits at Kourigha led to an alteration of the plans and the construction of a branch line 83 km long (150 km from Casablanca) Details of the phosphate deposits are given these deposits are remarkable both as regards high percentage of calcium phosphate and quantity available —**Emm de Margerie** Second report on the publication of the œuvres géologiques de Marcel Bertrand' —**V Romanovski** Some new classes of orthogonal polynomials —**M de Franchis** A recent theorem concerning quadrics —**Hadamard** Remarks on the preceding communication —**Rolf Nevanlinna** Remarks on the lemma of Schwarz —**Lucien Féraud** The Pfaffian systems of M Birkhoff —**G A Mokrzycki** The maximum utilisation of commercial aeroplanes —**Antonio Cabreira** The theory of a terrestrial metric planosphere —**Benjamin Jekhowsky** The identification of the minor planets and the correction of their orbits from a single observation —**J E Verschaffelt** The equation of Van der Waals and thermodynamics Reply to criticisms by V Karpen —**Quevron** The increase in the sensibility of electrical measuring apparatus with pivots The permanent magnet in the instrument is replaced by an electromagnet The power required is 150 watts, giving a magnetic field of 4500 gauss With this instrument it is possible to measure by direct reading 10^{-8} ampere or 10^{-3} volt Possible applications are discussed —**J Cabannes** The secondary radiations in light diffused by Iceland spar —**H Jedrzejowski** The groupings of radioactive atoms —**L Wertenstein** The β recoil —**André Chrétien** The ternary system water, sodium sulphate, sodium nitrate —**H Parent** The existence in Provence of a shore line at 6 metres, of recent Quaternary age.—**Henryk Arctowski** and **Edward Stenz** The origin of the dusts which fell in Poland between April 26 and 29, 1928 Proofs that the dusts which fell in Roumania and Poland on the above days originated in central Ukraine —**Joseph Devaux** The actinometric study of the penetration of the solar energy flux at the interior of some Pyrenees glaciers When the solar radiations penetrate the mass of glaciers, with the ice at 0° C, the absorbed energy produces a partial fusion of the ice, especially at the surface which becomes porous This porous condition reduces the transparency of the ice to the rays resulting in less penetration and less melting This process the author terms the radiothermic defence of glaciers —**Yossifovitch Mladen** The mechanism of the separation of the perithecium in the Erysiphaceæ and the rôle of the fulcra —**A Maige** The rôle of the cytoplasm in amylogenesis —**Lucien Daniel** The resistance to cold of the descendants of *Artemisia Absinthium* grafted on *Chrysanthemum frutescens* New varieties of absinthe plants, produced from seeds resulting from grafting Absinthium on Chrysanthemum, have proved very resistant to cold At the temperature of Rennes last winter (−21° C), numerous species regarded as acclimatised to the winter have been severely affected but the Absinthe arising from the grafts have survived —**H Lagatu** and **L Maume** The leaf diagnosis and its degree of security —**J Vellard** The properties of the cutaneous secretions of some tree frogs (*Hyla*) from the neighbourhood of Rio de Janeiro The toxicity of these secretions is as frequent in the group of Hylidæ as in other species The toxic characters vary greatly with the species —**R Fosse** and **A Brunel** The ferment producing allantoic acid by the hydrolysis of allantoin Its presence in the animal kingdom A ferment capable of giving allantoic acid from allantoin has been demonstrated in the frog and in several fishes —**Georges Lakhovsky** The sterilisation of water and of liquids by circuits in metal in direct contact with the liquid

University Staffs and Salaries

WHAT reforms in the present organisation of the universities of Great Britain other than *Oxford and Cambridge may be deemed necessary* for the continuance of their professed functions ? So long ago as September 1924 in the course of an article on university staffs and university finance we suggested that drastic changes were inevitable and probably imminent however unprepared for them the universities might be The publication of the Returns of the University Grants Committee for last year [1] encourages us to resume this urgent topic The Commissioners survey does not suggest that there has been any material change in the general financial position of the University Institutions concerned By a process of logic which must be somewhat unconventional the Commissioners infer from this statement that Steady if unsensational progress continues to be made Nothing stands still no disaster has attended the affairs of the universities so they must be progressing

The Commissioners have of course a very delicate and difficult task before them They represent a degree of official enlightenment rare in affairs of State The old order is still very much the old order in the universities The State s contribution last year represented very little short of three quarters of the salaries paid The policy of the Grants Committee is well known It is to make an end if possible of the prevailing gross under payment of staffs The salary bill is by far the largest presented to the universities—more than half the total expenditure which for the first time exceeds £5 000 000 The Grants Committee allocates £1 523 772 The total parliamentary grants reach £1 841 005 The first of these figures represents actually an excess over the million and a half promised The commitment was formerly only a million and in agreeing to increase it the Committee expressed the opinion that the greater part of the extra amount should be devoted to raising salaries This has not been done Some of the universities claim that it has been done but the figures contradict them The sum of £90 000 under the heading Salaries and Superannuation by which university expenditure for last year exceeded that in the previous year covers both increased salaries and the cost of new posts Since new posts number eighty four the sum devoted to correcting total inadequacy of remuneration could not have

[1] University Grants Committee Returns from Universities and University Colleges in receipt of Treasury Grant, 1927 28. Pp 24 (London H M Stationery Office, 1929) 3s net.

been enough for the needs of a single one of the larger institutions

We are where we were, and the optimism which leads the Commissioners to interpret some movements as necessarily progressive appears scarcely to be justified Had there been any real deference to the wishes of the Committee, it is evident that it would be revealed in an alteration in the proportion which salaries bear to total expenditure An approximation which takes us back to 1922–23 can be gained from the whole maintenance table in the Return which excludes Oxford and Cambridge 65 3 per cent in 1922–23, 65 3 per cent in 1926–27 and 65 9 per cent last year Another table provides the actual figures for the past two years for salaries and superannuation alone 50 03 per cent in 1926–27 and 50 4 per cent last year

From under payment of university staffs a whole train of evils proceeds While a sufficient number of eminent representatives of an earlier social and intellectual environment remain to give an appearance of dignity to academic pursuits there is and can be no assurance for the future so long as the standard of remuneration is one far exceeded by the earnings of many shop assistants, let alone professional men and those engaged in the vague if profitable service of the community 'business' so long as every interest', professional commercial or industrial, can attract the livelier and more competent from concern with fundamentals to concern with applications so long as modern educational demands however legitimate are permitted to prevent the performance of the avowed intentions of founders and patrons

In every human activity much depends upon the actual human beings engaged in its maintenance but it is doubtful whether this dependence upon the quality and devotion and performance of individuals is so absolute anywhere else as in the universities Their fellow citizens, even those of them who have personal acquaintance with a university, still retain a sort of inertia of reverence for it and for its sister institutions, as the fount and origin of knowledge The creative spirit in the arts and humane letters may and does rise to greater altitudes elsewhere, the same spirit in discovery, the fundamental natural law giving, whence all other discovery and invention proceed, can in modern conditions thrive nowhere else Here alone is the living knowledge, undiminished by secondary understanding and uncontaminated by the ageing falsity of books Shelley's question "as to how far a thirst for a happier condition of moral and political society survives among the enlightened and refined the tempests which have shaken the age in which we live' is answered in our own time, if the recompense of these excellencies is only penury and social excommunication

To advance knowledge and to extend science strictly interpreted—interpreted, that is to say as W K Clifford interpreted scientific *thought* as distinct from the slightly humbler use of other people s scientific thoughts—is a work for genius Those who possess it are a minority of academic workers, as they are a minority in the community as a whole They will always be attracted to university work irrespective of the conditions But that does not absolve the community from its responsibility If the flame of intellectual conquest burns so consumingly in such men that they will sacrifice every human and humane obligation for its satisfaction, the social conscience is surely guilty if while it is aware of the sublime benefits which are bestowed, it neglects to intervene for the protection of needy dependents If it seems then an act of folly or of genius to accept the present terms of most of the universities in Britain must we conclude that the majority who do accept these terms cannot be of the stuff which gives body to the intellectual resources of the country? The time must come when that will be true Those who possess what is after all a marketable talent can be retained in the service of the universities only at a just price

The earnest local patriotism and idealism which brought the newer universities into being did not in the first place correctly envisage the human and financial obligations involved, and are now inadequate to rectify the evils which have ensued State aid is directed particularly to reform, but reform is refused Why? The scarcity of relevant facts upon which an answer to this question might be based is one of the reasons which render the appointment of a commission with full powers so urgently necessary There is no common recognition of the claims of disinterested inquiry The politician in all his forms, parochial to imperial, promises wider and wider educational advantages, scholarships increase, but the real philanthropist is the academic worker The rich donor supplies only the bricks and mortar, it is the teacher and research worker who supply the human material at their own cost For true education or for self-advancement the community must be supplied with a superabundance of facilities, and the academic worker must pay the cost Organisation would of course soon bring the administrative mind to its senses, but organisation is prevented by cross-currents of sectional interest, by fear, by pride, and

not least by ignorance One faculty does not know what another does In consequence the presentation of the just claims of one against another is sometimes embittered and the sources of defeat may be disguised and concealed

Some incredulity may be occasioned by the statement that the universities have recently made an official representation for the purpose not of bettering the condition of staffs but of securing the withdrawal of existing forces which might be expected to achieve that end Resistance to trade union action is intelligible and these facts are not put forward without some sympathy with that view Nevertheless they indicate the danger underlying sectional and particularly professional representation of the university opinion One of the newer universities recently defended itself against a public charge by stating that the universities were powerless in the matter having merely to obey the General Medical Council Sixty six per cent of the Council are elected by the universities and colleges Powerlessness is therefore not apparent Too often faculties act for universities and in medicine the faculties are virtually the practising profession

At some time between the summer of 1926 and the end of 1927 the governing bodies of the universities asked for the withdrawal of a modest scale of remuneration for non professorial university workers which the British Medical Association had proposed to enforce In consequence a conference was held on Feb 10 1928 between representatives of the Association and representatives of the medical schools mostly deans These representatives created the impression that non professorial medical workers had many privileges and were at all events merely using the universities as stepping stones to lucrative practice A *non possumus* resolution was passed Last summer not this resolution but another exempting temporary workers and temporary workers only from the operation of the scale was passed by the Representative Body of the Association An amendment by the Hendon division which insisted that in no case could anatomists and physiologists be regarded as temporary workers was accepted rather dubiously by the chairman making this meaning clearer Very few weeks had passed however before the *British Medical Journal* contained advertisements for anatomists and physiologists at salaries £200 below the scale Inquiry elicited the information that the appointments were temporary although one man (at Sheffield) was to be equipped in every imaginable non clinical direction and able to take the place of the professor in his absence The medical profession fears—quite unnecessarily—that the present wasteful and absurd system of artificially favoured seniority will be jeopardised if young and brilliant men are made independent of patronage Other faculties fear preferential treatment which admittedly would be disastrous to the university idea But the example given is but one of the pernicious results of professional patronage and is worthy of the consideration of members of all faculties

Naturally the Returns refer to the comparative neglect of the Biological Sciences other than Medicine May we suggest that one of the matters considered by the Joint Committee which has been appointed to examine the practical steps which should be taken to secure the development of the teaching of Biology by co operation between the Universities and the secondary schools would very appropriately be the desirability of remunerating the teachers at least as well as the taught ? At one university where a scale has been sanctioned and re sanctioned it is impossible under the scale for any non professorial teacher to attain to a salary of £500 a year in less than thirteen years In some cases the men concerned could not be employed elsewhere at a salary below £600 for the first of these thirteen years

Sufficient has been said to show that inquiry and inquiry alone can now disentangle the multitude of interests involved Four years ago we said

It is absurd to pretend that under such conditions their normal duties can be efficiently conducted and an inquiry into the whole question of payment and the evils that are arising from continued under payment is undoubtedly urgent before the rot has time to inflict permanent harm on university teaching The rot advances Time which should properly be spent in research or recreation is used to supplement meagre and insufficient incomes Financial pressure and the vastly wider facilities for research under Government supervision drain from university service many men of superior ability The universities afford fewer and fewer opportunities of instruction at first hand by men actually engaged in the advancement of their subjects and the loss to students denied personal contact with original and creative minds will speedily destroy the whole significance of university training Already there are fundamental departments of science which have been neglected in England for a quarter of a century

No material change does not mean steady progress It means that decline is inevitable unless there is a substantial improvement of existing conditions

Ancient Knossos

The Palace of Minos a Comparative Account of the Successive Stages of the Early Cretan Civilisation as illustrated by the Discoveries at Knossos By Sir Arthur Evans Vol 2, Part 1 *Fresh Lights on Origins and External Relations, the Restoration in Town and Palace after Seismic Catastrophe towards close of M M III, and the Beginnings of the New Era* Pp xxii + 390 + 10 plates Vol 2, Part 2 *Town-houses in Knossos of the New Era and restored West Palace Section, with its State Approach* Pp xiv + 391 844 + 18 plates (London Macmillan and Co, Ltd, 1928) 147s net

IT is now nearly thirty years since the political liberation of Crete from Turkish rule made excavation possible on the site of ancient Knossos, and the knoll then called Kephála had been recognised, some ten years earlier still, as concealing a pre Hellenic building, one or two chambers of which—part of the famous 'palace magazines'—were indeed partially opened by a Cretan gentleman who had been appropriately christened Minos Almost without intermission since 1900—except in the War years—and under the single direction of Sir Arthur Evans, the dissection, and latterly also the reconstruction, of a 'Palace of Minos' has gone on, with ever widening scope outside the palace area, and ever growing wealth of experience suggesting re-examination of structures and substructures already recognised and cleared

In the first years of tentative discovery, a bulletin of each season's proceedings, in the *Annual* of the British School of Archæology at Athens, was publication enough Later came monographs, in *Archæologia* and elsewhere, on special enterprises, such as the opening of the 'Royal Tombs' hard by, and the first volume of "Scripta Minoa" on the earlier and mainly pictographic phases of the Minoan script The later 'linear' scripts still remain for the most part unpublished, though most of the documents were found quite in the earliest seasons' work Then in 1921 appeared the first volume of "The Palace of Minos at Knossos", bringing together in masterly perspective the main results so far as they concern the history of the site, and the chief phases of its civilisation down to the point at which it begins to be proper to speak of a 'palace' there at all Next came another interval punctuated with published studies of special problems, the paper on the "Ring of Nestor" and other remarkable pieces of engraved gold work from the Greek mainland, and the Huxley Lecture on early connexions between Crete, Libya, and the Nile Valley, and now we have the second volume of "The Palace of Minos at Knossos", ampler even than the first, but happily bound up in two sections, which make it a much less formidable implement of study and reference

This new volume does not merely take up the story where it was left by its predecessor As the author frankly says, "the excavation of Knossos itself may almost be said to have renewed its youth", it has been "a perpetual source of wonderment" to the excavator, supplementing, and almost invariably substantiating earlier observations and conjectures So multiple and diverse are these discoveries, that merely to marshal them in intelligible order is a notable achievement Habitual users will note with satisfaction that the pagination of the two parts of volume 2 is continuous, and also that the numbering of the sections is continuous with that of volume 1, a very great aid to concise reference

The sections contained in the two parts of volume 2 run from § 33 to § 67 inclusive, and deal mainly, though not by any means exclusively, with the latter part of the Middle Minoan and the beginning of the Late Minoan phases, that is to say, from about 1750 to 1500 B C Each deals at the same time with a separate topic or problem, and advances the general argument and historical reconstruction But since the appearance of volume 1 in 1921 a good deal has been done to clear up obscurities and supplement what was known then about the earlier periods, and §§ 33 34 serve also as a retrospect both of these years of work of the early Minoan and adolescent Middle Minoan phases, and of the general position of Crete and its culture in the ancient world

Beneath the central court of the later palaces, the discovery of late neolithic houses gives occasion (§ 33) to a revised estimate of the connexion between the earliest occupants of this part of Crete and the people of Asia Minor, which is represented as more directly concerned than the Greek peninsula, though it is still over-early to decide this point Western Crete has scarcely been touched yet, and very little has been done in mainland districts south of Argolis Moreover, even in Asia Minor the rugged south-western districts are still almost unknown, and comparisons between Crete and Cappadocia are necessarily provisional Geographically, however, access has always been comparatively easy from southern Asia Minor to Crete, thanks to the set of the current and the

regularity of the *imbat* winds, far more important for coastal traffic than the seasonal *meltem*

For this reason it may well be that eventual intercourse with the Nile Valley (§ 34) was for Crete rather an extension of this coastal traffic than the result of transmarine exploration Probably what gave this intercourse its vogue and vitalising force at both ends was the discovery that at the far extremity of the " Great Bight "—to modernise an Egyptian phrase about the ' great circuit of the lands "—it was possible to spread sail before a *meltem*, as the fruit boats of Cos do now, and regain the Nile mouths in a few days It is important, however, to distinguish (as is here done) Nilotic from other Libyan intercourse , and in early days it is the latter that appears to have been primary, as a number of distinct elements show , types of boats, hair dressing, costume, stone worked vessels, cupola tombs, and so forth In early dynastic times, when the Delta became Egyptised, Egyptian influence succeeds to Libyan in this Cretan ' staple ' or depot

How did this oversea traffic come ? By a ' transit road ' traced (§ 35) from minute ports nestling under the Asterusian ridge south of the Messarà plain, over the well guarded pass east of Mount Ida, and round the west shoulder of Mount Juktas, entering Knossos eventually by the Minoan viaduct (§ 36) with its caravanserai, bath house, and ' partridge fresco ' (§ 37), and the ' stepped portico ' (§ 38) rising into the south end of the ' palace ' site Special problems of technique and procedure confronted the excavator here, for the sintered soil was as hard as the masonry of the viaduct, and the spirits of the workmen had to be maintained by a fresh plan of remuneration The technique of Minoan commerce, too, demands special examination of the means of transport, ox, ass, eventually horse and mule , wheeled vehicles for goods, courier borne palanquins for notables, as a fragmentary fresco shows

What went by this age long road, and whither ? The answer (§ 39) comes from the signs of Minoan influence far away to the west and north, in Malta, the Iberian peninsula, even in Britain The connexion between early Maltese monuments and Minoan arts and practices has been disputed, more than once, and there is still a question of degree , but it becomes difficult to dissociate the decorative motives, and if these be borrowed from Minoan, the relative date of the Maltese culture seems to be determined, and therewith much in the western Mediterranean In the other direction, Cretan arts of design, already known to have affected Egyptian decorative work in the Eighteenth Dynasty, are now (§§ 40, 41) detected in a similar relation to the Middle Empire , a conspicuous instance is the recent find at Harageh, dated to the time of Sneferu II , about 1890 B C

Corresponding with the ports of the south coast, the harbour town of Knossos itself has been discovered and partially explored (§ 42) , but lying in the outskirts of modern Candia, and moreover in the zone devastated by both Venetians and Turks during the great seventeenth century siege, it contributes only suggestive details In addition to her other functions, the ' Great Goddess ' looked after seafarers, anticipating both Isis Pelagia in classical times, and the medieval Madonna Is it, however, certain that all these representations of potent or protective women are attributable to one and the same goddess, or rather (as Nilsson suggests in his " Minoan Mycenæan Religion ") to several, perhaps many, departmental deities ? Through this—and probably also through other ports on the north coast, Nirou Khani, for example (§ 44)—Crete was apparently brought into separate intercourse with Syrian centres, and their cults and manners (§ 43) illustrated by a fashion of bull headed libation vessels, and by occasional finds of cylinder seals Deeper seated are those aspects of Cretan religious belief which are illustrated by the insignia of a priest king from the French excavations at Mallia, and by the curious find at Nirou-Khani, which Sir Arthur Evans describes as a " propagandist depot ", of portable altars and double axes

After these retrospective and supplementary studies, resulting from the last few years' operations, the main thread of the story is taken up again in § 45 at the moment of the disastrous earthquake which wrecked Knossos during the Third Middle-Minoan period, and profoundly affected its subsequent fortunes The direct damage was serious enough, especially in the south-east quarter of the ' palace ', where the site had been greatly enlarged over substructures which now collapsed and overwhelmed the houses which occupied the slopes below But the moral effects were more lasting (§ 46) Propitiatory ritual before rebuildings was natural enough, and is illustrated graphically , but the new custom seems to have come to stay, in the form of a ' pillar-cult ', and the worship of an ' earth-shaker ' incarnate in bull-form, side by side with the god of the ' double axe ' (§ 47) and at times merged in him The general ' distress of nations ' after the disaster is shown directly by the marked reduction of the occupied area at

Knossos, and no less vividly by those emigrations of which the settlements on the Greek mainland about this time are the first fruits In quite a different direction, widespread ruin meant abundant opportunity for the builder and decorator (§§ 48 54) As we have seen in our own time, at such a period of 'reparations' the arts progress rapidly (§ 48), experiments are tried on every hand, foreign models have their vogue, and the copies of the first imitators pass into the common repertory of their successors Was it such a change of taste, or another earthquake (such as Crete seems to suffer about twice in a century) that brought about the 'scrapping' of the lovely painted stucco in the 'House of the Frescoes'—the "cultured home of a small burgher"—outside the Palace proper (§ 52)? And why were the 'scrapped' fragments so carefully stowed away in the house itself, to the delight of posterity? It is a further discovery (§ 53), that the decoration of house walls and other large scale work is the source and inspiration of the minuscule art and abridged designs of the pottery and perishable gear of everyday life

In these artistically favourable circumstances arose from the ruins of the 'older palace' the 'broad Knossos' of Homeric folk memory, in the golden age of Minoan Crete (§ 56) Fearless, because secure abroad, and therefore unfortified and unconfined, the growing population spent growing wealth on commodious suburbs, beyond the Kairatos river, for example (§ 55), and other Cretan towns flourished accordingly An eloquent signal is the rapid disuse of timber for house building, as in our own Renaissance, deforestation had begun

The remainder of the volume (§§ 57 67) surveys the reconstructed 'palace' in systematic order, beginning with the 'state approach' from the north-west (§ 57), the 'theatral area' for receptions and pageantry, the 'west court', and the 'treasure house' (§ 59), with its splendid hoard of bronze vessels and household furniture (§ 60), and the 'west porch' (§ 61) and 'south propylæum' (§ 62) with their processional frescoes, to which the well known 'cup bearer' belongs Here is the occasion for discussing the no less famous 'Keftiu tributaries' from the walls of Egyptian tombs, and the tell tale offerings which they carry (§ 63) So we pass on into the 'ceremonial corridor' (§§ 64 65), which runs north and south into the main mass of 'palace' structures, and so to the 'central court' (§ 66), where it has even been possible to recover the main architectural features of the façade, and to detect links between the religious ritual of the 'sanctuary quarter' of the 'palace' and the worship of Apollo at Delphi, a striking counterpart to the Greek legend of the Cretan origin of the Delphic priesthood, and to the worship of the 'Delphinian' Apollo at Knossos, and elsewhere in Crete, in Hellenic times

For the remainder of the Late Minoan buildings, and especially for the magnificent 'north gate' and its decorations, we have still to wait for volume 3, and still more have we to wait for an index, but it is only right to acknowledge the utility, meanwhile, of the marginal catch titles, and the analysis prefixed to each section and to admire the skill with which so vast and at first sight heterogeneous a collection of data has been arranged so that each topic occurs, like an episode of saga, in a context which is memorable in itself, and makes subsequent reference easy

That is in itself a feat of no mean art, as everyone will admit who has had to write reports of excavation So much that is found is always at first sight negligible or inexplicable, but for this very reason must be all the more scrupulously recorded and conserved So much, at the same time, that seems essential to any reconstruction at all, is *not* found, but has to be 'restored' with more or less confidence—and 'scrapped' sometimes, like any other hypothesis, as knowledge grows In Ægean archæology, knowledge has grown amazingly, though very unevenly, while Knossos itself has been under examination, even in Crete, American, French, Italian, Greek, and other British excavators have contributed much, especially to fill certain gaps in the Knossian series, for example, about the time of the great earthquake, and also in respect of those early periods, the deposits from which were levelled away from the top of the Kephála hill when 'palace' construction began With these exceptions, Knossos has remained, as it began, central and typical, and the record of its recovery is a classic of archæological literature

Scarcely less unusual than his presentation of results has been the excavator's treatment of the 'palace' as an exhibit and a place of study Nothing is more dreary or confusing than the litter of displaced fragments which disfigures most sites after excavation, except perhaps the knowledge that this or that important detail is 'now in London' or elsewhere Now, at Knossos, nothing has been removed, except to the Candia Museum for safe custody, nothing, on the other hand, of which the place could be ascertained, has been

allowed to remain out of that place, if the understanding of the whole could be facilitated thereby This has meant unusual expenditure and labour in reconstruction, the provision of facsimiles of fallen frescoes and other perishable detail, the unpicking and rebuilding of crushed or unstable walls Examples are apparent in the illustrations to this volume, and some of them are startling in their audacity, when they are judged by other people's practice But no one, it must be remembered, has ever had a site of this quality to study or to dissect under such favourable conditions, with complete continuity of direction, and concentration of responsibility and initiative Remote as Knossos is, and must remain, it is a place of pilgrimage for students of archæology—the art and technique of recovering the past—as well of antiquity, and it is only when the attempt is made to reconstruct the Kephála of thirty years ago from the recreated Knossos of to day that the full meaning of this record is appreciated

Incidental Natural History

(1) *Further Correspondence of John Ray* Edited by Dr Robert W T Gunther (The Ray Society Volume for the Year 1928, No 114) Pp xxiv + 332 + 4 plates (London Dulau and Co, Ltd, 1928) 12s 6d net

(2) *Physiologus a Metrical Bestiary of Twelve Chapters by Bishop Theobald* Printed in Cologne, 1492 The Author is believed to have been Abbot of Monte Cassino A D 1022–1035, and a Description of the Abbey is appended with Illustrations Translated by Lieut-Col Alan Wood Rendell Pp xxvii + 34 + 100 + 15 plates (London John and Edward Bumpus, Ltd, 1928) 10s 6d net

(1) THE Ray Society has already issued two works, the "Memorials" (1846) and the "Correspondence of John Ray" (1848), which may be said to have achieved their object of keeping alive the memory of "the greatest all-round naturalist of his time" The present addition, made possible by financial assistance from a revered and venerable successor of John Ray, Prof W C. M'Intosh, "is the outcome of a re-discovery in the Bodleian Library of a number of letters of John Ray which have not only never been printed *in extenso*, but which form a necessary supplement to the volume of *The Correspondence*" To these have been added materials obtained from the *Philosophical Transactions* and archives of the Royal Society, and from the British Museum The work has been edited by Dr R W T Gunther, to whose activities the history of science owes many useful contributions Although the short lives of Ray by Dale and Petiver are reprinted, Dr Gunther's volume is not, and does not pretend to be, a final biography of Ray in the form of a coherent narrative, and its interest lies rather in a series of disconnected incidents and opinions which nevertheless will be most valuable to the future biographer of Ray when he appears Ray is generally believed to have been born in 1628 and to have died in 1705 The dates inscribed on his tomb are 1628 and 1706 Both are now stated to be erroneous, the latter being corrected to 1705, and as regards the former, we have the evidence of the parish register that he was born in 1627

To give some idea of the contents of the volume, a few samples may be selected The letter on the anatomy of the 'Porpess", dated 1671, is printed in full, and illustrates fairly Ray's powers and limitations as an anatomist and a systematist It does not compare very favourably with the fuller account of the anatomy of the same animal published in 1680 by Edward Tyson Ray, however, clearly recognises and demonstrates that the anatomy of the porpoise must be interpreted in terms of the quadruped, which after all is the main point Nevertheless, in his "Historia Piscium", published in 1686, he still retains the Cetacea among the fishes He describes also the compound stomach of the porpoise, the lobulate kidneys and the mammal like genitalia Although he mentions the elongated larynx, he failed to recognise, as did all the older comparative anatomists, the existence of, and the reason for, an intranarial epiglottis The brain is briefly and accurately described, but he missed the external auditory meatus, which, though very small, had been seen by Belon and Rondeletius before him, and by Daniel Major and Tyson immediately after

An interesting account is given of the publication of Ray's work on fishes, the expenses of which plunged the Royal Society into a state of bankruptcy Samuel Pepys, at that time president of the Society, took a deep interest in this work, which was dedicated to him In spite of the fact that the cost of a number of the 187 plates had been guaranteed, there was a deficit of £360, and an attempt to dispose of 400 copies abroad at 25s a copy having apparently failed, the Society was unable to pay the stipends of its officers in cash, but offered them instead copies of this unremunerative

work It was sold at the time for 20s, and it may be noted that its present market value is about £3, 10s

Ray was naturally familiar with the horn of the narwhal, but had interpreted it as a median structure, and had not been aware, until informed by Edward Lhwyd, that the horn may be paired He, however, missed the significance of this variation, but regarded the paired condition as normal, "so that we are again to seek for a Monoceros, which we had thought we had found among fishes" It is somewhat surprising to find that Ray knew the work of Leonhard Baldner, the Strasbourg fisherman, who published the first observations on the metamorphosis of the lamprey in 1666 Ray, however, "not understanding high Dutch", was unable to make much use of Baldner's work, whose name, by the way, he mis spells Baltner

Some of the letters show that the mild and uncomplaining Ray could on occasion scarify his contemporaries, and in this respect he appears in a new light Walter Charleton comes in for severe treatment He "did not understand animals", his "Onomasticon Zoicon" was cribbed and inaccurate, and he is surprised that "such a book should find so much acceptance as to come to a second impression" Dr Woodward is arrogant, presumptuous, and highly conceited, his notions are ridiculous, but, adds Ray in mitigation, the interpretation of fossils is so difficult that "a man hazards his reputation that is positive and confident on either side"

We must express our indebtedness to Dr Gunther for this important collection of Raviana, and he has increased the obligation by preparing an index which covers not only his own volume, but also the previous collection of letters published in 1848

(2) This work includes an illustrated description of the famous Benedictine monastery of Monte Cassino, about 90 miles from Rome—a description which has some topical interest, since the Abbey is at the moment celebrating the fourteen hundredth anniversary of its foundation This description will therefore be useful to those who are visiting Rome, and may induce them to include in their tour an excursion to Monte Cassino We have not visited the monastery personally, but we would ask whether there is not something radically wrong with the date ascribed to the arcade figured in Plate 14

Col Rendell has performed a very useful service to learning by publishing a photographic reproduction of this important and fascinating incunable We wish that considerations of expense did not preclude the practice being generally followed Such a reproduction is practically as good for the purposes of study as the original, and we can only regret that the Bishop's inspiration did not run to the whole of the forty or so chapters of the "Physiologus" Col Rendell, however, has done more than reproduce his copy of this rare book—he has provided us with a translation of it, a serious task, of the merit of which there may be differences of opinion, but of which none will question the usefulness The condensed and at times erratic form of the original makes a literal translation, which Col Rendell has attempted, particularly difficult, and he has not always succeeded in the double object of abiding by the text and at the same time producing a version in intelligible English He confines himself largely to the 1492 edition of the Bestiary, and does not concern himself with the extensive literature of the "Physiologus", nor with discussions of such questions as a comparison of "Physiologus" with the "Nuzhatu l Qulûb", recently attempted by Col Stephenson

There are two appendices—one a partial translation of an Italian article on an unpublished moralised Bestiary of the twelfth century from the archives of the Chapter of Fano, and the other a comparison of the Fano version with the Cologne printed text of 1492, and another Latin version known as the Migne

Popular Astronomy

(1) *The Sun, the Stars, and the Universe* By Dr W M Smart Pp xii + 291 + 20 plates (London, New York and Toronto Longmans, Green and Co, Ltd, 1928) 12s 6d net

(2) *Astrophysics the Characteristics and Evolution of the Stars* By Dr W M Smart (Benn's Sixpenny Library, No 36) Pp 80 (London Ernest Benn, Ltd, 1928) 6d

RESEARCH in astronomy in these days is so fascinating and exacting a pursuit that one could understand, if not excuse, the neglect of one of the primary duties of investigators—to inform the general public of the progress of their science It is essential that this should be done by astronomers themselves, for, in the bewildering speed of modern progress, they alone have the least chance of seeing the position steadily and seeing it whole. Fortunately, they have not neglected their duty During the last few years there has been a remark-

able output of popular astronomical literature of a trustworthy type, and there is now no difficulty, as once there was, in directing an inquirer, of whatever intellectual capacity, to a satisfactory account of the astronomical knowledge so far obtained Dr Smart is the latest addition to the band of authoritative expositors, and the two books before us make it clear that he is well fitted for the task which he has undertaken

(1) The larger volume—"The Sun, the Stars, and the Universe"—' has been designed to present, in descriptive language and with an historical background, an account of modern astronomical discoveries and of present day views concerning the characteristics, constitution, and organisation of the heavenly bodies" This is a fair statement of its achievements, and indicates better than the title what aspects of general astronomy have been selected for consideration The order of treatment is not unconventional The first four chapters are introductory in character, dealing in general terms with the solar system, the celestial sphere, some aspects of early astronomical history, and astronomical instruments—the chapter describing the last named being inadequately entitled "The Telescope" Then follow two chapters on the sun, and one on the moon, planets, and comets, after which the various departments of stellar astronomy are discussed in eight chapters Three of these are devoted to the movements of the stars—an unusually large proportion, for which, however, there is much to be said It scarcely exaggerates the importance which stellar movements are likely to assume in the future progress of astronomy Two further chapters—on star clusters and nebulæ, and the universe, respectively—bring the book to a conclusion The illustrations are numerous and well chosen, and are excellently reproduced

The treatment throughout is as non technical as possible, and entirely non mathematical it does not, however, on that account suffer in accuracy or precision In one respect, perhaps, the ideal of precision has been followed too unswervingly Dr Smart states in the preface that when the chapter on stellar evolution was written there were three different evolutionary theories in the field, and it seemed advisable "in a popular book to devote the available space to a somewhat detailed account of one theory rather than to attempt to produce a condensed description of all three" It is at least questionable if the existence of a multiplicity of expert opinions on any matter is a valid reason for describing only one in a non polemical work—and particularly for giving "a somewhat detailed account" of that one It is doubtful, too, if the nebulous state of general opinion on stellar evolution can be said to contain anything so definite as "three theories" An appropriate vagueness in the tone (not the logical meaning) of the account of this subject, condensing here and there into the chief features of the various bodies of thought, would possibly have given a truer account of the actual state of affairs than a clear cut description of a particular view It is only fair, however, to add that Dr Smart makes no attempt to hide or disguise the difficulties and uncertainties of the subject

(2) The little volume on 'Astrophysics", which is a member of Messrs Benn's admirable Sixpenny Library, necessarily deals with much the same material as the later portion of the larger work It is carefully planned and is very successful in covering a great deal of ground without giving the impression of undue haste It is illustrated by several diagrams and is altogether appropriate to the character of the series of books to which it belongs

Dr Smart writes clearly and interestingly His sentences are rarely, if ever, ambiguous, and his accuracy is as great as can be expected of one man who undertakes to survey so vast a field The inevitable slips and misprints are few and unimportant He has, however, an unfortunate tendency of aiming at stimulating the imagination by the use of hyperbole This is sometimes merely ineffective, as in the frequent repetition of such words as stupendous' and amazing', and sometimes definitely misleading, as in the remark that the radial velocities of spiral nebulæ are 'incomparably' greater than the velocities of galactic objects (Incidentally, it may be questioned whether it is not the smallness rather than the greatness of the velocities of spirals that is most striking With a possibility of relative velocities up to the speed of light, is it not surprising and probably significant that independent universes should amble past one another at no more than about 1000 miles per second ?) This characteristic is expressive of the failure—far too general among writers of popular scientific books—to distinguish between the educated, non scientific man and the child Dr Smart is too able an expositor to be allowed to persist in this attitude without protest, and we trust that in his future writings he will give the same careful attention to the mental characteristics of his prospective readers as he does to the subject on which he writes

Our Bookshelf

The Application of Science to the Steel Industry By Dr W H Hatfield (Edward De Mille Campbell Memorial Lecture, presented in Philadelphia, October 10, 1928, at the Tenth Annual Convention of the American Society for Steel Treating) Pp vii + 154 (Cleveland, Ohio American Society for Steel Treating, 1928)

THIS volume contains the substance of a series of lectures delivered by the author in the course of a visit to the United States during last autumn, and deals with modern developments in the manufacture and use of steel As chairman of the Steel Ingots Committee, Dr Hatfield naturally gives prominence to the work of that committee, and lays stress on the importance of ingot structure for the quality of the finished steel This section forms a useful introduction to the subject, and is well illustrated The principles of heat treatment are next considered, again with the presentation of abundant material from technical practice

The metallurgist will naturally turn with great interest to the remaining four sections, dealing respectively with special engineering steels, corrosion resisting and stainless steels, steels intended for use at high temperatures, and with tool and cutlery steels On all these matters the author is in an exceptional position for the collection of full and accurate data, and his numerous tables form a most valuable compendium of information on such subjects In deference to the audiences before which the lectures were delivered, temperatures are given on the Fahrenheit scale, but the Centigrade values are added in brackets The author would render a service to metallurgy if he could persuade American workers to come into line with the rest of the world in this respect

Dr Hatfield has been very frank in including information which is often, for commercial reasons, difficult to obtain, and the volume, although small, will be frequently consulted, especially for the more complex alloy steels intended to resist creep at high temperatures, and other recent features of the industry The references to the literature are abundant, but marred by numerous minor inaccuracies The author is to be congratulated on a very useful piece of work

Praktische Einführung in die Morphologie der Insekten ein Hilfsbuch für Lehrer, Studierende, und Entomophile Von Prof Dr Eduard Handschin (Sammlung naturwissenschaftlicher Praktika, Band 16) Pp viii + 112 (Berlin Gebrüder Borntraeger, 1928) 11 gold marks

THIS handbook is designed to meet the need for a practical manual for the laboratory training of entomology students in the elements of insect morphology Its plan of arrangement is that each chapter is devoted to a separate region of the insect body, and is preceded by a short list of papers useful to the student for further reading The author, it may be added, has borne in mind the importance of explaining structure in terms of function By means of a series of judiciously selected types the student is led to understand the significance of the chief structural modifications found among representative insects A considerable number of common and usually easily procurable species are used as types for dissection, and having mastered the course laid down, the beginner should have acquired a sound general acquaintance with the external structure of these animals As a supplementary guide to practical work, a separate atlas of 23 plates is provided at the end of the book Its figures illustrate practically all features discussed in the text, they are models of clarity and are for the most part original The book can be recommended as a concise and thoroughly accurate laboratory manual

A D IMMS

The Industrial Uses of Bauxite with an Account of its Origin, Occurrence, Composition, and Properties By Dr N V S Knibbs Pp 141 (London Ernest Benn, Ltd, 1928) 21s net

DR KNIBBS'S book is a valuable contribution to the literature relating to bauxite, and it is therefore very regrettable that the price is so high Nine of the fifteen chapters are concerned with the uses of bauxite, a subject about which published information is rather scanty After a brief account of its occurrence and properties, the uses of bauxite in the manufacture of aluminium and its compounds, alumina refractories, abrasives and aluminous cements, and in oil refining, are all fully described In view of the great increase in the production of aluminium and the growth of a demand for aluminous cements, the possibility of a shortage of bauxite at some future date must be seriously considered, and in the concluding chapter Dr Knibbs discusses the utilisation of clays as substitutes Valuable lists of references are given at the ends of chapters

Notions fondamentales de chimie organique Par Prof Charles Moureu Neuvième édition entièrement revue et augmentée de nouveaux chapitres Pp ix + 657 (Paris Gauthier-Villars et Cie, 1928) 70 francs

THE new French edition of this well known textbook has been revised and brought up to date Several interesting chapters have also been added, dealing with the following aspects of applied organic chemistry substances possessing odour (pp 26) or taste (pp 7), organic medicinals (pp 47) and explosives (pp 14) We may note that the first of the new chapters contains no mention of the striking osmophoric properties of organic sulphur and selenium, and that the revised account of the carbohydrates, which scarcely does justice to recent researches, could be expanded with advantage The book may be criticised in these and other details, but the enlarged version, regarded as a whole, is characterised by the sense of proportion, logical presentation, and clarity of exposition which distinguished Prof Moureu's original text

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

An Isotope of Oxygen of Mass 17 in the Earth's Atmosphere

SINCE we reported the presence of an isotope of oxygen with mass 18 in the earth's atmosphere (NATURE, **123**, 318, 1929) we have found further confirmation Mr Harold D Babcock has sent us thirty four lines which were withheld from publication by Dieke and Babcock (*Proc N A S*, **13**, 670, 1927) because it was not known that they were due to oxygen Twenty seven of these are due to the alternate rotation levels of the 18 16 oxygen molecule Thus the 18 16 molecule has every rotation state where the 16 16 molecule has only alternate levels Such an excellent confirmation of the predictions of wave mechanics in this regard has not heretofore been possible since the presence of nuclear spin usually permits all states to exist although not in equal amount The more complete discussion of the data will appear elsewhere (*Jour Am Chem Soc*, May 1929) In the meantime Babcock, who obtained the data at Mount Wilson Observatory, has re examined his plates and also obtained additional measurements He has found a number of extremely weak lines in addition to extending the various 18 16 series, and has kindly permitted us to examine his manuscript in advance of publication (*Proc N A S*)

Babcock suggests that his new lines may be due to the forbidden 16 16 alternate rotation levels, although, as he points out, they fail to occupy the correct positions by several times his experimental error

We have found that these lines originate from a molecule consisting of an atom of mass 17 in combination with one of mass 16 The normal state of this molecule has one half unit of vibration, and both odd and even rotation levels exist Each of these facts is in accord with the theory of wave mechanics

The equations for the isotopic displacement are the same as previously given (NATURE, **123**, 318, 1929) except that 1 11 cm $^{-1}$ and 0 0294 cm $^{-1}$ should replace the values 2 12 cm $^{-1}$ and 0 0556 cm $^{-1}$ respectively Out of 22 new weak lines we find that 19 belong to oxygen 16 17 The algebraic deviation of observed minus calculated lines is $-0\ 03$ cm $^{-1}$ with a maximum deviation of 0 14 cm $^{-1}$

It is apparent from the comment of Aston (NATURE, **123**, 488, 1929) with regard to oxygen 18 that a mass spectrograph is unreliable in an initial or confirmatory investigation of isotopes present in very small amount It appears that the various known isotopes of the elements, their several chemical combinations and multiple ionisations, are not eliminated by existing technique, and suffice to explain nearly any future observation that can be made on an isotope present in very small amount This is, however, not the case in band spectroscopy, where the very characteristic fine structure having been found for an abundant isotope will lead to an equally characteristic counterpart We may thus conclude with certainty that oxygen isotopes 17 and 18 do exist in the earth's atmosphere

Babcock has carried out some very accurate intensity measurements to assist in the estimation of relative amount As we have pointed out in our more detailed paper (to appear *Jour Am Chem Soc*, May 1929) 18 16 molecules may be slightly polar, due to zero point vibration This would be expected, since the centre of mass does not coincide with the geometrical centre Such polarity may increase the absorption coefficient of the 18 16 or 17 16 molecules However, intensity measurements should lead to a maximum value Babcock estimates oxygen 18 as present to one part in 2500 He has, however, over looked a factor of two in his calculation, so that the estimate should be one part in 1250, as a maximum This factor is due to the fact that the 18 16 molecules have twice as many states in which to exist as have the 16 16 molecules

From Babcock's estimate of the relative intensity of the lines which are due to the 17 16 molecule we estimate its abundance as about one part in 10,000 as a maximum

Oxygen mass 17 has been reported by Kirsch and Petterson (*Ark f Mat Astron och Physik*, Stockholm, 19, 15, 1 16, 1925 *Phys Z*, **26**, 457, 1925) and by Blackett (*Proc Roy Soc*, A, **107**, 349, 1925) from data obtained on collisions between alpha particles and nitrogen nuclei These collisions occasionally lead to combination with subsequent elimination of a proton leaving oxygen 17 These experiments did not indicate the stability of oxygen 17, except that Blackett was able to show a life of at least 0 001 sec

A full account of our work will appear elsewhere

The Heat Production of Crustacean Nerve

IN my Ludwig Mond Lecture, published in NATURE of May 11, I referred to the experiments of Furusawa on the 'depolarisation' of crab's nerve by stimulation, and to the manner in which the 'polarisation' (as shown by the injury current) increases again to its original value in the presence, but not in the absence, of oxygen In a paper by Furusawa, shortly to be published in the *Journal of Physiology*, it will appear that this recovery process occupies a time of the order of half an hour I have recently succeeded in measuring the heat produced by crab's nerve, as the result of a 5 to 10 seconds' stimulus Some 98 per cent of this heat occurs in the recovery phase, only 2 per cent during the actual stimulus the recovery heat production lasts for 20 to 30 minutes at room temperature There is no doubt, therefore, that the process in which the injury current, diminished by stimulation, returns to its original value is accompanied by a relatively large liberation of energy

A striking fact is the small amount of heat set free in the initial phase, that is, during the passage of the impulse If we regard the nerve wave as accompanied by a surface change in the fibre which momentarily allows electrical contact to occur between inside and outside (it is difficult to picture the 'action current' otherwise), then activity will allow an equalisation of concentration of ions to occur between the two sides, a process which must be reversed during subsequent recovery The mixture of two salt solutions, say of potassium chloride and sodium chloride, involves very little change in total energy considerable work, however, may be required to separate them again, and this work will require a provision of energy, and in any actual process the liberation of heat

The crustacean nerve, as shown by Levin and by Furusawa, is highly fatigable, at any rate in respect of its electric change Corresponding to this, Meyerhof

and Schulz have shown in a recent paper in the *Biochemische Zeitschrift* that its oxygen consumption is high reckoned per gram of *dry* nerve, when stimulated, twenty times as high as that of a frog's sciatic, at rest ten times as high In a short stimulus I have found the total heat (initial plus recovery, spread over half an hour) to be about $2\,5 \times 10^{8}$ calorie per gram of fresh nerve per second of stimulus, as compared with 7×10^{5} calorie for the frog The crab's nerve is non medullated, the fibres of the frog's sciatic consist mainly of medullary sheath this may be one cause of the large difference between the two The fact that the crab's nerve contains a far higher percentage of water would work in the opposite direction

Whether the striking differences in fatigability, depolarisation, recovery, and energy exchanges between those crabs nerves and the sciatic of the frog are simply to be attributed to the fact that the former are non medullated and the latter medullated, only future work can show The central nervous system, which consists largely of nerve cells and to an appreciable extent of non medullated fibres, is far more fatigable and more dependent on an adequate supply of oxygen than is the peripheral medullated nerve It may well be the case that in the limb nerves of the crustaceans we have in such respects a much better model on which to work out the elementary properties of the nervous system than we find in the ordinary medullated nerve, which hitherto has been chiefly used for the purpose

The Inland Waters of South Africa

IN view of the forthcoming visit of the British Association to South Africa, we should like to direct the attention of biologists to certain remarkable inland waters occurring in that country Throughout the southern half of the Transvaal, as well as in many other parts of South and South west Africa, are found shallow saucer like depressions of various sizes which may be filled temporarily or permanently with water These pans have been ably described by Rogers,[1] and are generally admitted to be the result of wind erosion at a time when the climate of the country was drier than it is at present, although Passarge[2] considers them to have been the result of 'zoogenous' erosion in the Kalahari

We have examined a considerable number of these localities both on the Witwatersrand and in the Lake Chrissie region of the Ermelo district, an area of uncertain drainage from the edges of which arise the Vaal, Komati, and Usutu Rivers, and within which a surprisingly large number of pans occur.

From a hydrobiological point of view the Transvaal pans may be divided into temporary and permanent waters The *temporary pans* dry up in the latter part of the winter season, often leaving a few small pools, and fill with the first heavy summer rains They may be referred to the 'astatic' type of Gajl,[3] and normally support a rich phyllopod (s str.) fauna We have found it convenient to subdivide the temporary pans of the southern Transvaal into *grass-pans* and *mud pans* The pH of the former is below 8 0 when full, and the soil of the bottom does not become sufficiently 'brak' to inhibit the growth of a rich terrestrial vegetation on drying When full, such localities support a large number of aquatic flowering plants, and a very abundant and varied tycho plankton, characterised by the association of *Volvox* spp with the rotifer *Conochilus hippocrepis* The *mud pans*, on the other hand, have a pH of more than 8 2 when full, and presumably their floor is too 'brak' when dry to allow the growth of abundant terrestrial vegetation The plankton is far more restricted than is that of the *grass pans*, phytoplankton is almost absent, and rotifers rare, the bulk of the organisms inhabiting such localities being crustacea

In the Lake Chrissie area the majority of the pans are permanent Chemical conditions are very variable and are reflected in corresponding differences in the fauna and flora The most interesting condition was met with in a series of pans, all less than a mile in diameter and perhaps 10 20 feet deep The water of these pans has a pH of about 9 0, is slightly salt (0 02 0 03 *N* Cl), coloured from pale yellow to deep sepia by humic material, and may be very turbid Such pans support practically no higher vegetation or phytoplankton and have a zooplankton composed almost exclusively of one or two species of Centropagid copepods and a large and remarkable Daphniid The largest pans, for example, Lake Chrissie itself, which is about three miles long, may support a rich growth of *Potamogeton Livingstonii* (Moss forthcoming publication) In striking contrast to these pans may be mentioned a pair of pans lying close together on the farm Weltevreden to the south of Lake Chrissie One of these, which is slightly alkaline, supports an exceedingly rich growth of *Melosira* and a few other algæ and is slightly alkaline, the other, which is just on the acid side of neutrality, contained large numbers of desmids and a very rich rhizopod and rotifer fauna

Naumann,[4] in his latest contribution to lake typology, characterises the *dystrophic* type of water as being on the acid side of neutrality, poor in electrolytes and containing considerable amounts of humic matter, while the *oligotrophic* type of Thienemann[5] is divided into *oligotrophic* (s str) on the acid side and *alkalitrophic* on the alkaline side of neutrality The more extreme type of permanent pan containing large amounts of humic matter must be considered as *dystrophic*, but differs from Naumann's characterisation not merely in alkalinity, but also in containing large amounts of electrolytes (chiefly sodium bicarbonate and sodium chloride with some calcium, magnesium, and sulphates), including accumulated phosphates, up to 0 006 mgm P_2O_5 per litre, which cannot be utilised owing to the lack of phytoplankton The poverty of the planktonic flora must be attributed to the combined influences of alkalinity, turbidity, and colour of the water as well as to the direct toxic action of the humic matter Since both acid and alkaline waters may be classified as *dystrophic*, it would seem better to abandon the term *alkalitrophic* type and to revert to Thienemann's earlier scheme, recognising, however, an alkaline as well as an acid phase in the *oligotrophic* and *dystrophic*, if not in the *eutrophic* type Other cases of *alkaline dystrophic* waters are probably recorded in the literature without their true nature being recognised, for example, Turner's Lake, Isle au Haut, Maine[6] Dr S C Ball also kindly informed us that very salt humic waters may occur in the lagoons of coral atolls when completely shut off from the sea In such a case a *salt dystrophic* lake may be formed supporting only a population of *Artemia*

Normal acid *dystrophic* waters also occur in South Africa, but are chiefly of artificial origin, for example, the various reservoirs on Table Mt from which the water supply of Cape Town is derived The Transvaal pans by no means exhaust the hydrobiological wealth of the country , on the Witwatersrand are found very acid waters (pH 3 7) contaminated with nitre cake from gold extraction works, which support a restricted fauna The alkaline vleis near Cape Town also deserve passing mention

A detailed report on the chemical conditions and planktonic life of all these localities is in preparation and will be published as soon as our collections have been worked out by the various systematists who have kindly undertaken to examine them Our very best thanks are due to Prof L T Hogben, of the University of Cape Town, who first directed our attention to the remarkable field offered by South Africa for this type of research , to Dr A W Rogers, director of the Geological Survey of South Africa, for bringing to our notice the Transvaal pans, to Prof J A Wilkinson, of the University of the Witwatersrand, who generously placed his facilities for chemical analysis at our disposal, and to Prof C E Moss and his staff, of the same University, and to Miss E L Stephens, of the University of Cape Town, for valuable botanical information

Vegetation Formulæ

THE value of floral formulæ in indicating at a glance the systematic position and affinities of a phanerogam has so long been recognised that no apology is needed for suggesting that a comparable means of expressing the general character of vegetation types is both eminently desirable and likely to prove of great value to the ecologist and phytogeographer At the present time the personal factor inevitably enters largely not only into the description of vegetation, but also into the interpretation of descriptions After some years of residence in the drier parts of India and Burma the *Acacia* thorn forest and *Acacia* scrub, both with an undergrowth mainly of grass, had become two of the most familiar types of vegetation, yet I was unprepared for the extraordinarily close comparison which is possible with large areas of the Bush Veld of Southern Rhodesia or with certain types of mulga scrub and mallee scrub which I found on visiting South and Western Australia Yet a vegetation formula, such as is now proposed, would have indicated the affinity at a glance It is essential that the formulæ shall be kept as simple as possible, so that they may be used by travellers and explorers with only a slight knowledge of botany, but will at the same time impart a valuable precision to their observations.

The formula depends upon two separate considerations:

(*a*) The enumeration of plants over a definite standard area.

(*b*) The recognition of four or five main groups of plants for this purpose.

It has long been the custom of forest officers to study their forests by 'sample plots' and of ecologists to base detailed descriptions on similar plots. It is proposed that one hectare be taken as the standard area Of course the enumeration may be carried out over any sized area and the results reduced to the standard area Thus a hectare is equivalent to 2 47 (roughly 2½) acres and is equal to 10,000 square metres, so that the enumeration of small plants may be made on the basis of a square metre It is necessary to have a large standard area to cover adequately tropical vegetation where there may be but one or two individuals of a particular species even in a dense equatorial forest, or the widely scattered vegetation of a semi desert

It is suggested that, for practical purposes, the types of plants to be enumerated may be considered as divisible into five broad groups trees (A from Lat *arbor*), shrubs (F from Lat *frutex*) herbaceous plants (H from Lat *herba*), grass (G from Lat *gramen*), and cryptogams (C) It is recognised that *herba* is not a very satisfactory word, but its use in the sense proposed (excluding grass) is already widespread in the adjective herbaceous The basal vegetation formula is thus

$$xA + yF + zH + x'G + y'C,$$

where x, y, z, x , and y are the numbers of individuals per hectare For broad descriptive purposes it will often be possible to ignore C entirely

For trees and shrubs the presence of more than one story may be indicated by duplicating the symbol thus

$$A + A' + F + F ,$$

whilst the general character of the trees or shrub may be indicated by suffixes such as e (evergreen), d (deciduous), c (coniferous) The average height of the vegetation is important and should be expressed in metres For all types of vegetation the letters a, b, c, d, etc , may be used to indicate dominants , x, y, z, etc , to indicate the absence of dominants or presence of numerous species To take a very simple example

$$150\ A^{c}a(30)$$

is the formula for a coniferous forest with one dominant (a), with an average height of 30 metres and averaging 150 trees to the hectare

It is significant of the lack of precision in many of our existing descriptions of vegetation that I have not exact figures for any of the types of vegetation described in my "Vegetation of Burma" (1925) and in the *Journal of Ecology* (1923), but supplying estimates, four types of vegetation may be selected to indicate the use of the formulæ

(1) *Indaing*
$$= 300A^{e}abx(20) + 50F^{e}y + 10^{4}(2Hz + 10Gmnz')$$
(2) *Diospyros* forest
$$= 200A^{e}bcdex(12) + 50F^{e}y + 10^{4}(Hz + 10Gmnoz')$$
(3) *Acacia* thorn forest
$$= 150A^{e}efx(7) + 100F^{e}y + 10^{3}(5Hz + 20Gmnz')$$
(4) *Acacia* scrub
$$= OA + 150F^{e}efy(2) + 10^{2}(2Hz + 5Gz')$$

TREES a = *Dipterocarpus tuberculatus*, b = *Pentacme suavis*, c = *Terminalia tomentosa*, d = *Diospyros birmanica*, e = *Acacia catechu*, f = *Tectona hamiltonii*

GRASSES m = *Andropogum contortus*, n = *A apicus*, o = *A serratus*

It is obvious that the four examples chosen form a continuous gradation (actually the result of decreasing moisture).

If the principle of vegetation formulæ is acceptable to ecologists, numerous refinements and extensions will be necessary, but the present outline scheme is put forward with the hope that it may induce a greater precision of description by travellers It is to be

noted that the formula is at least partially complete without the *naming* of the constituent species, it may also be noted that a formula can be drawn up from a study of scaled photographs, and even approximately in the case of forests from aerial photographs

Distribution of Temperature in the First 25 Kilometres over the Earth

SIR NAPIER SHAW, in his "Manual of Meteorology", gives on p 100 of vol 2 a very interesting diagram showing the distribution of temperatures in the upper air over the globe. As pointed out by Dr C W B Normand in his review of the book in the *Quarterly Journal of the Royal Meteorological Society* (vol 54, p 275, 1928), the diagram does not represent exactly the peculiarities of the distribution of temperature in the stratosphere over the tropical and sub tropical regions. An attempt has therefore been made to prepare a modified diagram, using all the data now available. It shows (Fig 1) the probable distribution of isotherms in the atmosphere up to 25 km in summer and winter over the northern hemisphere. The dotted lines are based on very few observations and are therefore mainly conjectural. The principal features of the diagram may be briefly summarised

(1) The stratosphere is not isothermal over any particular place, but above a certain level there is a tendency for the temperature to increase with height

(2) The coldest air over the earth, of temperature about 185° A, lies at a height of some 17 gkm over the equator in the form of a flat ring surrounded by rings of warmer air

(3) The surface of the tropopause has a relatively steep slope towards the pole between latitudes 30° and 50° in summer and between 25° and 45° in winter

(4) The ring of lowest temperature at the tropopause is displaced towards the summer hemisphere

(5) There is a ridge of high temperature in the tropopause between latitudes 20° and 40° N in summer corresponding to the ridge of high pressure at 8 km over those latitudes (see Sir Napier Shaw's chart of 8 km isobars in July, *loc cit* p 262)

The evidence for (1) and (2) comes from the results of sounding balloon ascents at Batavia, Agra and in the United States of America (Blair, *Bull Mt Weather Obs*, vol 4, part 4, pp 183 304, 1912). The rise of temperature with height in the stratosphere over these places cannot be considered to be due to insolation, as most of the Agra ascents and many of the American ascents began late in the day when the sun was low. Bemmelen has given strong reasons for believing that the rise of temperature in the stratosphere which he observed over Batavia could not have been due to insolation. The Agra and Batavia results indicate a temperature of about 220° A. at a height of 24 km, and the American results show about 230° A. at 25 km

The seasonal variation of temperature of the tropopause at Batavia and Agra is illustrated in Fig. 2 and shows (4) clearly. The height of the tropopause over

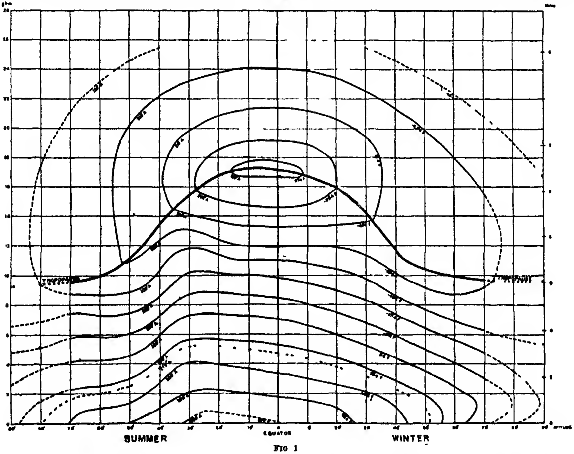

FIG 1

Batavia does not show such well marked variation as that of temperature, but the following figures taken from Bemmelen (*Proc Roy Acad*, Amsterdam,

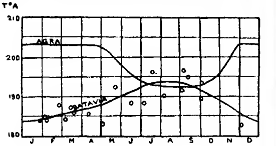

FIG 2 —The points marked in the figure refer to Batavia temperatures

vol 20, p 1313) show that the variation is similar to that which occurs over Agra but displaced by about six months

Heights of Tropopause over Batavia (km)

Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
17 8	17 6	17 3	17 0	16 5	16 2	16 0	16 5	17 0	17 4	17 6	17 7

The lower temperatures and greater heights of the tropopause in summer are presumably due to the stronger convection in the troposphere in that season

The persistent increase of temperature with height for at least 5 km above the tropopause in the tropics finds a natural explanation if we assume that the tropopause marks the lower limit of the ozone layer in the atmosphere K R Ramanathan

Meteorological Department,
Poona, India

Significant Figures in Speed Records

I had hoped that someone more competent than myself would have replied to Col O'Gorman's letter, in which, in Nature of Mar 30, he offered an apologia for recording Sir Henry Segrave's speed to 8 significant figures, but probably most readers of this journal do not consider that motor speed records form a subject with which they are intimately concerned It would, however, be regrettable if this silence led the general public to conclude that scientific workers are prepared to accept as valid a speed recorded to one hundred thousandth part of a mile per hour

Col O'Gorman commences his letter by admitting that the last figures are merely arithmetical residues, with which all will agree, but unfortunately in what follows he seems to attempt to justify the inclusion of these readings in the published value of the speed and to this objection may fairly be taken His first argument is based on the necessity for great precision in order that there may be no doubt whether a standing record has been beaten by a subsequent attempt or no Let us examine this argument a little more closely Sir Henry Segrave's mean time for the mile over his two runs was 15 56 sec, the automatic timing being carried to 1/100 sec, and the mile apparently assumed to be absolutely accurate A subsequent claimant to the record may do one of the following five things

1 He may beat the record by a substantial margin, in which case a statement to the nearest mile per hour would clearly be sufficient

2 He may beat it by a narrow margin. We will take the nearest margin which can be recorded, one-half of one hundredth of a second (the time being the mean of two runs each of which is measured to 1/100 sec) This will make his time 15 555 sec, and his speed 231 44 miles per hour (or if we give the arithmetical residues, 231 43683 m p h)

3 He may take precisely the same time to the half hundredth of a second as Sir Henry Segrave (15 56 sec) with a speed of 231 36 miles per hour

4 He may take one half hundredth of a second longer when his speed will be 231 29 miles per hour

5 He may fail to obtain the record by a substantial margin

Now in cases 2 and 4, to determine whether the claimant has obtained the record or not, it is amply sufficient to record the speed to 1/100th of a mile per hour The difference from the standing record in each case amounts to 0 07 or 0 08 mile per hour In case 3 no addition to the number of significant figures will serve to distinguish between the new record and the old It is difficult to find any support for 8 significant figures from these facts

Col O Gorman next points out that the speed published is not the true mean of the speeds obtained on the two runs over the measured distance, but the sum of the two distances divided by the sum of the two times It is not clear how this fact affects the question of the permissible number of significant figures which is governed solely by the accuracy with which the time and the distance can be measured One may further ask why, if it is wrong to round off to two decimal figures, it is right to stop at five figures? Why not publish a whole page of decimals?

It would perhaps be presumption on my part to suggest a line of defence which Col O'Gorman might have adopted, which could not be assailed on the scientific side He might have pointed out that these speeds to be accepted internationally must be worked out in the manner laid down by the international controlling body, and that any country which attempts a record and wishes its claim to be recognised must follow the prescribed rules The Royal Automobile Club, therefore, would be under an obligation to give the prescribed number of figures whatever this number might be It may publish a foolish statement, but no alternative is open except that of not claiming the record, and few people would wish to push the claim for scientific honesty to this length

The Spread of Scale Insects and their Parasites

Many years ago I was an industrious collector of scale insects and mealy bugs, especially in Jamaica I found them in great abundance on cultivated plants, and obtained many species When recently travelling in the Oriental tropics, I was struck by the relative scarcity of these insects, and the occurrence of various well known injurious forms only in small patches or isolated individuals Perhaps the difference was partly due to the relative poorness of my eyesight, but I could not help speculating on the causes which might lead to a diminution of scale insects on cultivated plants, aside from the operations of economic entomologists World wide commerce has spread the injurious Coccidæ over the earth, as they are so easily carried with plants In their native countries they are efficiently controlled by parasitic and predatory enemies In several well-known cases a plague has been abated by going to these countries and obtaining the natural enemies, which had failed to arrive with the first (accidental) importation of the coccids Thus, following the modern expansion of trade and rapid transit, there has been in many regions a great increase in the damage done by scale insects, at times reaching the magnitude of a calamity But by the same process,

gradually but surely, the natural enemies will also spread In the course of time, almost imperceptibly, they will gain the ascendancy, and the coccid plague will cease, never to return unless through the importation of a new sort of coccid Thus it may even happen in some cases that a rigid quarantine, after a pest has arrived, may be harmful, preventing natural enemies from following it These latter may, however, be brought in by entomologists, through special permission, provided they have been found and recognised

There is some proof that this is not mere speculation I wrote to Dr L O Howard, who has long paid special attention to the parasites of Coccidæ, and he directed my attention to a study he had made, comparing the scale insect parasites of the United States (Chalcidoidea) with those he had studied and described in 1880 There was no doubt that in the years since that date the parasite fauna had changed owing to the introduction of many foreign species, which had in some cases supplanted native ones Furthermore, the recent researches of Garcia y Mercet in Spain, and Silvestri, Masi, and Paoli in Italy, indicated the existence in great numbers, in the Mediterranean region, of Aphelinine parasites apparently unknown there seventy five years ago Last year, when I visited the Melbourne Botanic Garden (which has about 16,000 species of plants growing in the open), Mr St John informed me that there were not nearly so many coccids on the plants as formerly This may partly be due to native enemies, thus the Red Wattle bird keeps the fluted scale (*Icerya purchasi*) in check, yet I suspect it may also be due largely to the spread of foreign parasites

Similar-looking coccids may have quite different natural enemies The citrophilus mealy bug (*Pseudococcus gahani*), though an ordinary looking species, was not controlled in California by the many enemies of the native American mealy bugs Now, after an extended search, *Pseudococcus gahani* has been found apparently native in Australia, and two species of Hymenopterous parasites, a Dipterous parasite, two kinds of Coccinellid beetles, and a Chrysopa have been observed to keep it within bounds in that country These have now been taken to California, and there are already indications of favourable results California's plant quarantine would have prevented them from coming over accidentally, and in any case the deliberate work of the entomologists is infinitely superior to the slow operations of chance

Variation of the Intensities in the Helium Spectrum with the Velocity of the Exciting Electrons

Recently, Peteri and Elenbaas (*Zeits f Phys*, **54**, p 92 1929) have published curves of the intensity variations of the helium lines when the velocity of the exciting electron steam is altered We have been working on the same subject, and since our results do not agree with theirs, it seems worth while to give a preliminary account of them

We also use a photographic method of measuring the intensities, but the apparatus for exciting the light is different A narrow electron beam in helium at 0·024 mm pressure passes into a field free box and produces a narrow streak of light An image is thrown on to the spectrograph slit and runs perpendicular to it We integrate the intensity over the length of the spectrum lines and subtract the background which is due to secondary excitation In this way we completely avoid errors due (1) to secondary excitation, and (2) to the variation of the spatial distribution of the electron beam with the applied voltage

The results for the lines 3889 ($2^3S - 3^3P$) and 3965 ($2^1S - 4^1P$) are shown in Fig 1 The scale for the two lines is arranged for the maximum of the two curves to be equal The results of the Utrecht workers are shown dotted for comparison We cannot explain their curves except by the supposition that a large fraction of the light from their tube was due to excitation by secondary electrons

The interesting feature of our curves is the extremely different behaviour of the singlet and the

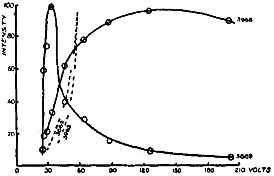

Fig 1 —Intensities in the helium spectrum

triplet lines This is a general characteristic of all the lines, though individual cases show minor variations The following conclusions may be stated

(1) For high exciting velocities, the triplets vanish in intensity compared with the singlets This has been predicted theoretically by Oppenheimer, and had previously been found experimentally by Hughes and Lowe (*Proc Roy Soc*, A, **104**, p 489, 1923), with whose results ours agree very well in general

(2) For low exciting velocities, the singlets are weak compared with the triplets This is a new result Since the normal state of He is a singlet state, this seems to indicate for low velocities a very close coupling of the spin of the exciting electron with the spins of the electrons in the atom

There is another interesting point of dissimilarity between the singlets and triplets We find that while the light of the triplets is confined closely to the electron beam, the light from the singlets tends to spread away from it This makes the intensity determinations of the singlets somewhat arbitrary We are not at the moment prepared to discuss the cause of this behaviour as the investigations are not yet complete

The Longitudinal Distribution of Photoelectrons

The new quantum mechanics has completely resolved the problem of the photoelectric effect. In fact, Wentzel (*Zeit für Phys*, **40**, 574, 1926 **41**, 828, 1927) and Beck (*Zeit für Phys*, **41**, 443, 1927) have succeeded in justifying theoretically the well known Einstein equation, and the more complete treatment of Sommerfeld has permitted the calculation of the dissymmetry of the photoemission, that is, the experimental fact that the forward emitted electrons are in a greater number than the backward ones. Sommer-

feld's theory is, however, a first approximation, valid only when the wave length λ of the incident rays is fairly large compared with the dimensions of the atomic radius. With these conditions, considering electrons emitted from the K level, the probability $P(\theta)d\theta$ of emission of a photoelectron at an angle comprised between θ and $\theta + d\theta$ is proportional to

$$\left\{1 + \frac{18}{5}\frac{v}{c}\cos\theta\right\}\sin^2\theta d\theta \qquad (1)$$

and the mean impulse σ acquired by the electrons in the direction of the propagation of the rays is given by

$$\sigma\frac{h\nu}{c} = \frac{18}{5}\frac{4}{10}\frac{h\nu}{c} = 1.44\frac{h\nu}{c}$$

Williams (NATURE, April 13, 1929) has demonstrated that this formula is in agreement with the experimental results, because recent experiments made in nitrogen and in oxygen lead to a value of σ ($\sigma = 1.40$), nearly equal to the theoretical one.

Equation (1) is, however, only a first approximation, and it remains to be determined what is the formula of distribution valid when Sommerfeld's approximation is not enough. We have made the calculation for the K level without any limitations for the value of λ. We have obtained a very complicated formula, that in a first approximation, when

$$\lambda \gg \frac{h}{2mc}$$

gives the (1), and in a second approximation leads to the following expression

$$\left\{1 + \frac{18}{5}\frac{v}{c}\left[1 - \frac{135}{56}\frac{RhZ^2}{mc^2} + \frac{45}{112}\frac{v^2}{c^2}\right]\cos\theta\right\}\sin^2\theta d\theta$$

where R, h, m, c, and Z are well known constants.

Substituting for those their values, we have

$$\left\{1 + \frac{18}{5}\frac{v}{c}[1 - 6.41 \times 10^{-5}Z^2 + 0.40]\cos\theta\right\}\sin^2\theta d\theta \qquad (2)$$

According to (2), in the second approximation we have a variation from Sommerfeld's value, depending upon the atomic number Z, but of little entity, and a greater variation from the velocity of the photoelectron in the opposite sense. The agreement obtained in the case considered by Williams remains also in the second approximation. In fact, for nitrogen ($Z = 7$) irradiated with rays of $\lambda = 0.6$, the ratio v/c is equal to 0.28, and formula (2) gives for σ quite the same value as formula (1) ($\sigma = 1.41$).

The deviations from the value of σ calculated by (1) are sensible for the heavier elements. In fact, if one obtains with $v/c = 0.1$, $\sigma = 1.40$ for argon ($Z = 18$), which is a value a little different from that of Sommerfeld, for krypton ($Z = 36$) one obtains $\sigma = 1.33$.

For very hard rays the effect of the second order, depending on the velocity, is more conspicuous. So if v/c is equal to 0.6, one obtains for argon $\sigma = 1.61$, and for krypton $\sigma = 1.53$. These values are not in agreement with those obtained by Auger for argon.

Further experiments may decide this question.

Details of the calculation will be published elsewhere.

Dragonflies in Folk-lore.

IN recent years NATURE has adopted the very interesting departure of taking notice, by review or otherwise, of contemporary novels which hold some special interest for science, either (as in the case of H. G. Wells's "William Clissold") because of the recognised biological outlook of the author, or (as in the case of Aldous Huxley's "Point Counterpoint") because of some exceptionally expressed criticism of modern science, its aims or its outlook.

This attitude might well be adopted also towards novels which contain accounts or records of the popular outlook in times past towards natural objects, whether living or inanimate. Recently it has been my good fortune to read a novel which has already been acclaimed as a modern masterpiece, namely, the late Mary Webb's "Precious Bane". It is full of quaint archaically expressed observations of Nature in the countryside. The time is about the end of the Napoleonic wars. The chapter on dragonflies (book 3, chap. v.) is well worth reading from this point of view alone, and I would like to ask readers of NATURE whether any of the expressions in the following passage are still in use in Great Britain:

We called the dragonfly the ether's mon or ether's nild at Sarn, for it was supposed that where the adder or ether lay hid in the grass, there above hovered the ether's mon as a warning. One kind, all blue, we called the kingfisher, another one with a very thin body the darning needle. Mother was used to tell Gideon that if he took dog's leave or did other mischief the devil would take needle to him and use the dragonflies to sew up his ears, so he couldna hear the comfortable word of God and would come to damnation. But I never could believe that the devil could have power over such a fair thing as a dragonfly.

I believe dragonflies are still quite commonly called 'devil's darning needles' in many parts of the United States of America, but whether the adder is still called the 'ether', or the dragon fly the 'ether's mon' or 'ether's nild' in any part of England or America I do not know. Perhaps some readers of NATURE could enlighten me.

The species called the 'kingfisher' would evidently be *Calopteryx virgo* L., while the 'darning needle' must have been either *Agrion puella* L. or some other common damsel fly, perhaps *Enallagma cyathigerum* Charp.

Periodic and Spiral Forms of Crystallisation.

IN a recent letter to NATURE (April 20, p. 603), Hughes has suggested that the interesting spiral markings on carborundum reported by Menzies and Sloat (Mar. 9, p. 348) may be a special case of periodic crystallisation. Hughes refers to a remark in a paper by Miss Henley and myself (*J.C.S.*, 2725, 1928) concerning the formation of spirals in Liesegang rings as anomalies caused by accidental external conditions.

The periodic crystallisation of thin films of sulphur described by Hughes was previously investigated by Fischer Treuenfeld (*Kolloid Z.*, 16, 109; 1915) and by Kohler (*ibid.*, 17, 10; 1915), and an account of this and other examples of the same phenomenon is given in Hedges and Myers' "Physico-chemical Periodicity" (Arnold and Co., 1926) on pp. 34-37.

Some months ago I carried out some experiments on the crystallisation of thin films of molten organic substances and found that crystallisation in concentric rings readily takes place with benzil, benzoin, benzophenone, menthol, *m*-dinitrobenzene, and acetanilide. The experiments were discontinued, but I hope to return to them shortly: at present, the observations made are in the main in agreement with the views expressed by Hughes on the cause of the phenomenon.

I have examined the specimens to see whether there is any indication of the occasional formation of spirals in place of the usual concentric rings. The accom-

panying photograph (Fig 1) clearly depicts the spiral growth of crystals This specimen was made in Sir Henry Miers' laboratory at Manchester in 1924 by allowing a thin film of potassium dichromate solution to evaporate on a warm microscope slide The structure differs from that of the specimen of sulphur in Hughes s illustration and from most of my specimens, in that crystallisation started from the periphery of the drop and travelled inwards, instead of beginning

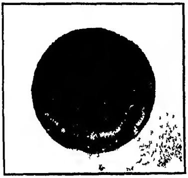

FIG 1 —Spiral crystal growth × 25 diameters

at a central nucleus and radiating outwards The specimen of carborundum described by Menzies and Sloat may have crystallised in this way

Where crystallisation starts from a central nucleus, I have not observed among the specimens an example of the immediate development of a spiral, but I have a specimen of camphorsulphonic acid, crystallised from ethyl acetate solution, in which a true spiral succeeds two concentric rings surrounding the nucleus of crystallisation Moreover, examination shows that a disturbance has been caused at the point where the spiral begins by the presence of another nucleus in the vicinity

There appears to be no doubt, therefore, that crystallisation does sometimes follow a spiral course to give a variety of periodic structure, and it seems probable that the markings on carborundum are to be explained in this way ERNEST S HEDGES

The Atomic Weight of Phosphorus

IN a recent issue of NATURE (Mar 9, p 390) mention is made of the fact that the English Commission on Atomic Weights adopts for the atomic weight of phosphorus the value 30 98(2), this being based on Aston's results with the mass spectrograph, whereas the German Commission adheres to the older and higher value 31 02, derived mainly from gravimetric analysis

The following results, obtained by the physico chemical method of density and compressibility as applied to phosphine gas, may therefore be of interest

Density L_0^{760} at one atmosphere, 1 5317

Density L_0^{760} at one half atmosphere, 1 5243

Assuming the compressibility factor to be a linear one, the value for $(1+\lambda)$ so obtained is 1 0097, which, in conjunction with the values for oxygen of 1 4290 for the normal density and 1 0009 for $(1+\lambda)$, leads to the molecular weight of 34 00(2) for phosphine and to 30·97(9) for the atomic weight of phosphorus

Further experiments are being carried out at the pressures of three quarters and one quarter atmosphere, to ascertain whether the compressibility can be taken as a linear function of the pressure Such results as have been obtained at one quarter atmosphere give the value $L_0^{760} = 1\ 5208$ for which $(1+\lambda) = 1\ 0096$ and P = 30 98(2) MOWBRAY RITCHIE

The Atomic Weight of Copper

WITH reference to the Research item in NATURE of April 27, p 660, that Messrs Richards and Phillips have recently found the atomic weight of copper to be 63 557 (Ag = 107 88), it may be interesting to note that the spectroscopic value given in my "Analysis of Spectra" (p 127) is 63 5569 ± 0 060, the 0 06 referring to maximum possible errors The probable error is much less The value obtained on spectroscopic data depends on the doublet separation and the $p(1)$ term These are known with very great accuracy in both silver and copper

W M HICKS

Quantum Geometry

DIRAC'S wave equation for the electron involves a Hamiltonian linear in the momenta p_k This fact seems to be of geometrical nature and suggests the introduction of a linear fundamental differential form

$$ds = \sum_k \gamma_k dx_k$$

with matrix coefficients γ_k in geometrical considerations

This linear ds is connected with Dirac's wave equation in the same way as the Riemannian ds^2 with the relativistic wave equation of the older theory

The matrix vector γ_k may be interpreted as an operator corresponding to the fundamental velocity, namely, that of light, and is connected with the Einsteinian $h_{\nu a}$ by the relation $\gamma_\nu = \sum_a h_{\nu a} \gamma_a^0$ where γ_a^0 are Dirac's constant matrices

Possibly other tensors of the second rank, like the energy tensor T_{ik}, or R_{ik} are to be replaced in the proposed 'linear geometry' by matrix vectors in the same way as g_{ik} is replaced by γ_k

The linear geometry seems to furnish a basis on which a uniform theory of gravitation, radiation, and quantum phenomena is to be constructed More detailed considerations on this subject will appear in the *Zeit f Physik* V FOCK

Early Use of Iron

THE early history of iron outlined in the address by Prof Louis (NATURE, May 18, p 762) has been carried much further back by discoveries in South Palestine, published in *Gerar* last year Furnaces were found dated to 1100 and 1175 B C, the earlier was 67 in × 36 in At the side of the furnace lay great hoes, 11 in × 5 in, plough socks, and a pick of 6 pounds weight, showing that iron was as commonly used then as now The earliest example was a knife of 1350 B C, and this accords with the date of the polished steel dagger of Tutankhamen This year another steel dagger, with cast bronze handle, has been found, of about 1300 B C, as it was snapped in two anciently without any bending, it could not be soft iron FLINDERS PETRIE.

University College, W C 1

Einstein's and other Unitary Field Theories An Explanation for the General Reader

By Prof H T H PIAGGIO

I

THE announcement of the publication of Einstein's new theory has aroused great interest even among those who do not usually follow the advances of science Unfortunately, this interest has been accompanied by a feeling that the new theory, like Einstein's earlier ones, is a mysterious mixture of metaphysics and mathematics, so obscure and paradoxical that the average man cannot possibly acquire any notion of what it is all about Indeed, a French author declared that " when two German professors meet, and each can understand what he says himself, but cannot understand the other, they are said to be talking Metaphysics If, however, the subject of discussion is so profound that they are unable to understand not only each other, but even themselves, it is called the Higher Metaphysics Now Einstein's Theory belongs to the Higher Metaphysics "

The purpose of the present article is to dispel such views By going back to the work of Newton and Maxwell we can trace the general nature of the ideas that have been uppermost in Einstein s mind It will be shown how the desire for unification of apparently different physical phenomena was the guiding force in each case Other attempts at unification of gravitation and electromagnetism will be explained and contrasted with Einstein's It is hoped that, by simple considerations concerning the meridians and parallels of longitude on the earth's surface, readers without any mathematical knowledge may be able to grasp the general nature of the principles underlying the new geometries

NEWTON AND GRAVITATION

When Newton (1642–1727) started to consider the subject of planetary motions, he found in existence fairly accurate knowledge of the facts, but only the wildest speculations as to the underlying causes Thus Kepler (1571–1630), by analysing the astronomical observations of Tycho Brahe (1546–1601), had found three laws of planetary motion One of these was that the orbits were ellipses with the sun in the focus Kepler even guessed that universal gravitation might have something to do with these laws, but he also considered them as partly due to a magnetic force set up by the sun's rotation Descartes (1596–1650) thought that space was filled with vortices of ether, and the planets were dragged round by these vortices like sand particles in a whirlwind

It was Newton's magnificent combination of physical intuition and mathematical power that enabled him to sweep aside these vague ideas, and to set up what we may call a unitary theory, which explained on a single basis effects hitherto believed to be due to more than one source He showed that gravitation alone, acting between every two particles of the universe with a force proportional to the product of the masses divided by the square of the distance between them, was sufficient to account for all the phenomena of planetary motion It is interesting to notice that at first Newton's theory of gravitation appeared to be disproved by the observed facts concerning the moon and the earth This caused Newton to put aside his ideas for several years When a more accurate set of observations was available the theory was vindicated Its substantial correctness is conclusively proved every year by the truth, to a very close approximation, of the astronomical predictions of the *Nautical Almanac*

MAXWELL AND ELECTROMAGNETISM

We now come to the twin sciences of electricity and magnetism The investigation of their mutual relationship was due to several investigators, among whom Faraday (1791–1867) takes a prominent place Then came Maxwell (1831–1879), who, in what are now well known as Maxwell's Electromagnetic Equations ", gave mathematical form to Faraday's ideas and extended them Maxwell's theories, which united electromagnetism and light, were criticised at the time, and even Lord Kelvin was of opinion that " up to the present the so-called Electromagnetic Theory of Light does not seem to have accomplished much " One term in Maxwell's equations (representing what is called a displacement current) seemed to owe its origin to an illegitimate union of mathematics and metaphysics Worst of all, there seemed no experimental verification of the consequences of the equations This was not forthcoming until after Maxwell's death, and was due to Hertz (1857–1894) The electric waves the existence of which was implied by Maxwell's equations were actually produced, and they may now be received every night by the millions who listen to radio concerts

EINSTEIN'S SPECIAL THEORY (1905)

Long after Maxwell's equations had been firmly established for a fixed system, there was grave doubt as to how they should be extended to a moving one In order to explain the results of the famous Michelson Morley experiment, FitzGerald and Lorentz introduced the remarkable hypothesis of a contraction caused by motion Einstein (1879–   ) showed that the phenomena could be accounted for on the basis of the hypothesis that the velocity of light and all other electromagnetic phenomena would be exactly the same for two observers who were moving with uniform velocity relative to each other This was based on the measurement of time by light signals, an idea which seemed fantastic in those days, but an equivalent idea, the fixing of time by electromagnetic signals sent out by radio from Daventry or Paris, has now become a commonplace in many households

Those who scoffed at the idea of time being any thing but an absolute quantity must now see that it is at least possible that the clocks regulated by

the radio signals from the Eiffel Tower, based upon observations at the Paris Observatory, might not agree exactly with those sent out from Daventry and based on observations at Greenwich This discrepancy, conceivable in any case, would become more so if France and the Eiffel Tower were moving away from Daventry with enormous velocity But the contraction of rods and the slowing down of clocks, to which so much attention has been directed, are (as pointed out by Eddington) only apparent Nothing really happens, except that each observer is unable to get an accurate idea of what length and time really are in the other system The only accurate way to take measurements in a system is to travel with it, and if this is impracticable, as in the case of an electron moving with a speed which is an appreciable fraction of that of light, our measurements of both space and time concerning the electron are slightly different from what they would have been if we could have travelled with it These slight differences are related to each other This is what we mean when we say that space and time form a four dimensional continuum

There is no need to try to imagine a fourth dimension, but calculations, to be accurate in the case of high velocities, must deal with time as well as with the three dimensions of space In this sense the theory united space with time, and so was a unitary one It also united electricity more closely with magnetism, for it showed that what appears to be a purely magnetic field in one system will appear to be a purely electric field in another system moving relative to the first Moreover, it united mass (inertia) and energy, showing that one can be transformed into the other This has since been confirmed in the case of the helium atom, the mass of which is slightly less than the sum of the masses of the nucleus and the electrons which compose it The discrepancy is made up by the potential energy stored up when the electrons and nucleus are packed closely together

In spite of this discussion of mass and energy, we can say broadly that Einstein's Special Theory was fundamentally an electromagnetic one, having no connexion with gravitation Its experimental basis was a slender one, and even such as it is, it has been called in question by Miller, who claims to have obtained, at great distances above sea-level, evidence of the ether-drag of which Michelson and Morley, at about sea-level, found no trace (In spite of the elaborate precautions against error that Miller took, there is a general disposition to reject his results) Perhaps the chief service rendered to science by the Special Theory was the help it gave in arriving at the general one, with which we will now deal

Physical Basis of Einstein's General Theory (1915)

In the dynamics of Newton, the same number, the *mass*, appears to measure three entirely different properties, namely, the quantity of matter, the inertia (or difficulty of setting it in motion), and the weight (the force exerted on it by the earth) Is this merely a marvellous coincidence ? Einstein thought not, and inferred that inertia and weight are probably two aspects of the same phenomenon, due to something in the nature of space (or rather of space time) Again, everyone knows the queer feeling of falling when a lift starts to descend, or of heaviness when a descending lift is coming to rest Weight, in fact, seems to alter when in a system, like a lift, which can be accelerated

This suggests a connexion with relative motion, which, for uniform velocity, was considered in the Special Theory These considerations led Einstein to seek hypotheses concerning space and time which would incorporate the results of his former theory and at the same time account for inertia and gravitation In other words, he was led to seek a new geometry

Abstract and Physical Geometry

How can there be a new geometry ? Most of us had it fixed in our minds that geometry was a fixed and unalterable science Did not Euclid, starting with axioms that were self evident truths, reach conclusions which will stand for all time and, moreover, can be verified by sufficiently careful drawing ? This is certainly what we gathered from Blank and Dash's "Geometry for Schools", but it rests upon a confusion of ideas

First of all, there are two distinct kinds of geometry, abstract and physical The first starts with certain *undefined* terms, such as point, straight line, and plane, and makes certain *unproved* statements, called axioms (or postulates), about them Then we deduce consequences from these definitions and axioms, which constitute abstract geometry The whole structure is purely a sort of building game, in which the definitions and axioms, taken more or less at random, furnish the bricks, and we see what we can build with them There is no necessary connexion with the physical world, and so it is meaningless to inquire whether the axioms are true or self evident To vary the metaphor, they are the rules of the game, and may be changed at will if we want to construct a new game Euclid's geometry in its ideal form, when it reasons entirely from the definitions and axioms (an ideal not realised in any school geometry), is one system of abstract geometry But so long as the science is only an abstract one, we are at liberty to start with a set of axioms quite different from those of Euclid We shall see later that by studying the properties of a sphere we can build up a system called Riemannian geometry, of which Einstein makes great use

We now come to physical geometry, the science that deals with the results of the draughtsman, the surveyor, and the architect, and expresses the properties of rulers, set squares, plumb-lines, and other physical objects Of course, Poincaré was right when he asserted that we can assume any system of geometry we like (and no doubt most of us prefer the simplest, namely, Euclidean), and then explain any observed physical phenomenon, however strange, by attributing it to some physical force However, Einstein preferred to proceed otherwise, and exercised his free choice of an

abstract geometry in such a way as to sacrifice some of the simplicity in the geometry to gain as much as possible in the physics For example, in his theory there is no need of a gravitational force to make a planet move in its orbit, for this orbit is as natural in his geometry as is a straight line in the geometry of Euclid and Newton This is what is meant by 'the geometrisation of physics', and we may define physical geometry as that one of the many possible systems of abstract geometry which is most successful in giving a simple account of physical phenomena The experience of draughtsmen and others shows that Euclidean geometry works very well indeed in ordinary terrestrial affairs, so physical geometry cannot differ very much from Euclidean

---

The Origin of Adaptations[1]

By Dr E J ALLEN, F R S

BY an adaptation is meant nothing more than a character of an organism, which has enabled a species to survive itself as such, or to survive until it is transformed into another species It is survival that gives the measure of the value of the adaptation Survival can only occur if the whole organism is adapted to the environment to an extent that suffices Organism and environment must be thought of as a unity, as interlocked and fitted closely to form that harmony which is Nature and life Organic evolution is a phase—the crowning phase, may be—of cosmic evolution The biological environment determines survival no less than the physical, and adaptation to both must be sufficient The environment is not fixed, but must be thought of as in a condition of perpetual flux and change This is true especially of the biological environment, for species once common may practically disappear, and years later may reappear abundantly with devastating effect on other organisms

The general physical conditions under which organisms live have been well discussed by L J Henderson in his book "The Fitness of the Environment" (1913) Henderson discusses the unique properties of water, carbonic acid, hydrogen, and oxygen, and shows how they are specially fitted for the purposes of organic life "There are no other compounds which share more than a small part of the qualities of fitness of water and carbonic acid, no other elements which share those of carbon, hydrogen, and oxygen" "None of the characteristics of these substances is known to be unfit or seriously inferior to the same characteristics in any other substance" "The fitness of the environment is one part of a reciprocal relationship of which the fitness of the organism is the other"

Darwin's answer to the question, how does the adaptation of organism to environment come to be, was based on three factors—heredity, variation, selection In ultimate analysis the fact of heredity depends on the cellular structure of organisms and the phenomenon of cell division When a living cell divides, its most essential substance, the germ plasm, separates into two portions which are almost equal But we cannot so easily obtain an insight into the problem of variation For simplicity's sake, consider first the formation of a germ cell from its mother cell in an organism which is developing parthenogenetically The researches of the colloid chemist have given us the picture In imagination enlarge the germ mother cell until you see the two phases, the liquid, the mass of molecular aggregates varied in size and shape, until you see the long, complex chains of atoms, building up the heavy molecules which form the aggregates, until you see the solar systems in miniature of protons and electrons which are the atoms—a seething, churning mass, active with the activity of cosmic forces, receiving matter and energy constantly from the surrounding medium, and giving them back The preparations for cell division begin, the molecular aggregates arrange themselves in new patterns, the separation of the cell into two parts ensues Is it a matter for surprise that the partition of pattern and of substance is not always, perhaps is never, exact? We cannot wonder that germ cells thus produced differ in small respects among themselves A few molecules more or less, a few atoms more or less, a few electrons even more or less, may mean large changes in the offspring into which the germ cell grows We are, I think, safe in concluding that lack of equality in the partition of the hereditary material is one important cause of variation If we think on similar lines of sexual development, where instead of one we have two germ cells uniting to form the zygote from which the offspring is developed, the probability of variation between parent and offspring, and between different offspring of the same parent, is obviously much increased

Weismann was the first to draw a clear and sharp distinction between true hereditary characters and modifications of the body or soma, produced by the direct action of physical changes in the environment, and to develop the conception of the continuity of the germ plasm The germ plasm is the transmitter, in unbroken continuity from generation to generation, of hereditary qualities The body or soma is its temporary guardian, perishing when the work of transmission has been done Blastogenic characters, as Weismann called the true hereditary characters, reappear in exactly the same form in the offspring as they show in the parent, provided both parent and offspring have grown up in the normal environment Few now question that the nucleus is the essential organ of the germ cell which is engaged in the transmission of hereditary characters Few

[1] Extracted from the Hooker Lecture, delivered before the Linnean Society of London on Mar. 14

also question that the chromatin of the nucleus is the bearer of definite factors or genes, or that these factors are distributed in linear order in the chromosomes which appear at the time of cell division In ordinary normal development, hereditary characters are determined by the factors in the germ plasm in response to stimuli furnished by the environment, for in the absence of a suitable environment no development at all takes place If the environment is normal the characters are reproduced in normal form

Hereditary *variations* are differences from the parental characters, which appear in the offspring, and are transmitted by the offspring to its descendants We can only study them when the environmental conditions, in so far as they affect the characters concerned, remain unchanged throughout the growth of both parent and offspring and this is the recognised basis of all breeding experiments These hereditary or blastogenic variations we now call mutations, and mutations, according to the most recent usage of the word, may be either large or small, it being quite impossible to distinguish them from any other variations by the factor of size alone In this respect the word mutation as now used does not convey exactly the same idea—it is not so limited—as Darwin's words 'sport' or 'monstrosity', and its meaning has been somewhat changed since it was first introduced by de Vries The modern view is that mutations are heritable changes in the characters of organisms, which are due to definite alterations of the factors or genes, situated in the chromosomes of the germ cells Contrasted with these mutations we have somatic modifications, the acquired characters of Weismann, the reaction of the organism to definite changes in the environment De Vries's term 'fluctuations' is now generally employed in the same sense, and has, I think, ceased to be useful

The variations or deviations revealed by the measurements of biometricians, which group themselves around a mean or modal value, according to the 'law of error', are probably in part small mutations which can be transmitted to descendants, and in part somatic modifications which are not so transmitted With adequate measurements for a series of consecutive generations, the statistical tests which the biometrician applies enable him to say whether or not any of these deviations are inherited, and to give a measure of that inheritance To take an example, it is frequently maintained that Johannsen's experiments with garden beans (*Phaseolus vulgaris nana*), which multiply by self fertilisation and from which he obtained what he regards as pure lines, have proved that individual differences as shown by these lines are not inherited, and that therefore they cannot provide material upon which natural selection can act Pearson, however, maintained, so long ago as 1910, that the pure line theory demands that the offspring shall be as highly correlated with the grandparent as it is with the parent, whereas Johannsen's own figures show that the coefficient of correlation between offspring and parent is higher than that between offspring and grandparent These experiments should be repeated with larger numbers of measurements

Mutations may be classified into 'combination mutations', those due to rearrangement of factors or genes already present, and 'alteration mutations' due to changes in the factors themselves Evidence is now forthcoming that the germ plasm itself can be acted on by physical and chemical forces in the environment in such a way that mutations are produced Heslop Harrison's work on the production of melanic forms in Geometrid moths was described (see NATURE, Jan 22, 1927, p 127) This work is of outstanding interest, not only on account of the fundamental importance of the results attained, but also for its perfect combination of acute and penetrating observations in the field with critical and long sustained experimentation Harrison has shown quite clearly that the germ plasm can be changed by chemical substances contained in the food of an animal, or in more general terms that the germ plasm can be altered by the environment Another important advance in the same direction has come in H J Muller's account (*Science*, July 1927) of his production of mutations in *Drosophila* by irradiating spermatozoa or oocytes with X rays When the correct dosage had been found, many mutations were produced, which on the whole were similar to those previously reported in *Drosophila*, such as 'white eye', 'miniature wing', and 'forked bristles' Most were recessive, but a number were dominant

One further point with regard to variations must be noted The possibilities of variation of an organism are strictly limited and circumscribed by the general physical and chemical properties of protoplasm The essential physiological processes, upon which the life and activity of organisms depend, are comparatively few Digestion, growth, sexual activity follow the same general lines throughout the whole animal kingdom It is probable that the physico chemical mechanisms alike of all muscular movement, of the movement of amœba by pseudopodia and of the movement of cilia, will fall into one general scheme Similarly, the transmission of the nervous impulse is being shown to proceed on essentially the same lines in animals of widely separated groups The essential physiological processes already function in the protista If the physiological processes are few and circumscribed, variations in structure and form will be limited also, recognising that form is "a product of an inner physiological activity" (Kusnetzov D'Arcy Thompson, "Growth and Form", 1917)

The last of the three principal factors on which Darwin based his theory of evolution was natural selection, or in Herbert Spencer's phrase, which Darwin adopted, "the Survival of the Fittest" Later, Ray Lankester suggested another formula, "the elimination of the unfit", which describes more correctly the meaning of the conception That natural selection, acting on heritable variations, is *a* factor in fixing adaptations is almost a

truism But whether it is the only factor, whether it is sufficient by itself to account for the living things we know, each fitting so perfectly its own little niche in its world, is a more difficult question The process is of necessity so slow But the time available is enormous, and geologists and physicists seem satisfied that it is to be reckoned in tens, if not in hundreds of millions of years We must consider also whether the mutations that occur are sufficiently diverse, for if adaptations are to be selected, mutations in the direction of those adaptations must occur The known mutations of *Drosophila* amount to some 400, but the mutations so far studied are, for practical reasons, those which are large and obvious There is increasing reason to think that they are outnumbered by small mutations which only long practice can detect Many mutations studied are slight colour changes, because they can be distinguished with remarkable precision by the practised human eye Correspondingly minute changes in size or shape would be very hard to detect, and to study them by breeding experiments and the methods of Mendelian analysis is not yet possible We can only form judgments about them by analogy with results from larger mutations There remains the statistical method of attack, by the study of mass populations of successive generations The method is efficient, active, and advancing, and it can only be lightly disregarded by those who have failed to grasp its meaning

Alternative or additional theories to account for evolution are favoured by many naturalists Darwin himself attached much importance to characters being inherited which had been produced by constant use or disuse in the parent This is a particular case of Lamarck's conception of "the inheritance of acquired characters", or, better expressed, of somatic modifications Some authorities consider that experimental proof of such inheritance is already available for example, MacBride cites the work of Kammerer and of Durkhen and Brecher, the latter work being supported also by Heslop Harrison On the other hand, Graham Kerr ("Evolution" London Macmillan and Co, 1926) advances strong arguments on the other side, and Goodrich ("Living Organisms", 1924) takes the same view "The real question Biology has to answer in future, as O Hertwig has pointed out, is not 'Are modifications inherited?' but 'How are new factors acquired?'"

Even if it could be proved experimentally, without possibility of question, that somatic modifications were inherited, we should only have advanced a little way towards an understanding of our problem The question *how* the soma influenced the factors in the germ cell would remain In this connexion Cunningham's suggestion that hormones provided a capable instrument is of interest, and might be followed up experimentally

The more elusive notions, which introduce the idea of some psychic or psychoid influence, controlling and regulating the processes of metabolism and organic growth, it is hard to distinguish from the animisms of primitive man, who finds a spirit on every mountain, a devil in every bush All these ideas contain a suggestion of purpose, some of them an idea of almost conscious purpose such as we know only in ourselves, or by analogy assume in higher animals, in each case associated with an elaborately differentiated nervous system They are brought into the story at the point where knowledge based on observation and experiment ceases, at the point where it seems to many of us more satisfactory to say frankly, I do not know

The idea of orthogenesis or nomogenesis (Berg, 1926), the idea that development takes place in a predetermined direction, is certainly unsatisfying in its elementary form An explanation of adaptations on these lines offers special difficulty, for the theory fails to provide the flexibility necessary to produce that constant adjustment of the organism to its ever changing environment which is imperatively demanded If, to reach the required adjustment, a predetermined direction of variations and of evolution is postulated in the organism, a predetermined evolution of the environment on parallel lines would surely be necessary That evolution proceeds according to laws of the same character as other laws of Nature, is the common basis of all modern evolutionary theory, and was held perhaps more strongly by Darwin, Huxley, and Weismann than it is by some writers of to day The physical laws in accordance with which the processes of growth are controlled, with results that we see in so many curious patterns, from the simple branching of a tree or of a nerve fibre to the elaborate spirals of a shell or of a growing plant, or again, the laws which lie behind the varied shapes, so curious and wonderful, of organisms and of their different parts,—these laws, and many others like them, still call for serious consideration and research This is the valuable feature of the theory of orthogenesis and in directing renewed attention to it, its followers make a valued contribution to biological thought

There are many other aspects of the problem of the origin of adaptations that might be considered, but it has seemed better to confine ourselves to the larger questions, even at the risk of saying nothing but what was already well known The outlook for biology to day is as alluring and as full of hope as it was in those years of joyful enthusiasm which followed the historic paper by Darwin and Wallace, communicated to the Linnean Society by Hooker in 1858 In whatever direction we look problems bristle, problems open to successful attack, and the old qualities, insight, patience, and determination, will get them solved But we must not limit the outlook, and all aspects of biological research must proceed hand in hand Botany, zoology, palæontology, the work of the systematist and of the field naturalist, the study of structure and the study of function, the work of the embryologist and of the experimental physiologist, of the geneticist and of the statistician, all are necessary, and none can succeed without the others

News and Views.

THE President of the Board of Trade has appointed a committee to report whether any, and if so what, amendments in the Patents and Designs Acts, or changes in the practice of the Patent Office, are desirable This committee may be regarded as the result of the suggestive report on the Reform of the British Patent System, issued by the British Science Guild in October last and reviewed in detail in NATURE of Nov 17, 1928 (vol 122, p 757) This report was the work of an expert committee of which Dr W H Eccles was chairman and Capt C W Hume, honorary secretary It immediately aroused the keenest interest throughout the country and even abroad, and was generally considered to be a very valuable document Nearly thirty professional institutions and organisations representing the industrial and business world appointed committees to consider the report, and a number of these are understood to have endorsed its findings in general terms, with reservations in matters of detail in some cases

AS no particular interest, to say the least, was taken in the British Science Guild report by the Board of Trade when it appeared, it is probably not too much to assume that the public attention since given to the report has now, after a lapse of seven months, led the President of the Board to appoint an official committee to consider the same subject The chairman is Sir Charles Sargant, a former Lord Justice of Appeal, and the members are Mr Horatio Ballantyne, a chartered patent agent and a director of Messrs Lever Brothers, Mr H A Gill, a chartered patent agent and member of several previous committees on patent matters, including the international conference of 1925 and the British Science Guild committee, Mr E H Hodgson, of the Board of Trade, Sir Herbert Jackson, Mr W S Jarratt, Comptroller General of the Patent Office, Mr Fearnley Owen, a solicitor, Mr J G Weir, a member of the Glasgow firm of engineers, and Mr James Whitehead, of the patent bar, who was chairman of the Dating of Patents Committee, 1927 The secretary is Mr R W Luce, a member of the non technical staff of the Patent Office We suggest that the absence of any representative of the electrical industry is to be regretted, since British industry is likely to be profoundly affected by electrical developments during the next decade, but perhaps the officials of the Board of Trade consider that the electrical aspects of the subject are sufficiently represented in the British Science Guild report

BY means of the Government grant of £100,000, and more than £180,000 collected by the *Times*, a very large sum is now available for the purchase of radium for Great Britain Prof F A Lindemann, in the *Daily Telegraph* of May 15, raised the question of justification for the present price of radium. The ordinary expectation is that when a chemical product is made the subject of large-scale operations, the price of the product will diminish With radium the reverse has happened, for when it was produced on a very small scale, the bromide of radium in a high state of purity could be sold, presumably at a profit, for about 32*s* per milligram of radium element content Large scale production was first attempted in America with the low grade ore carnotite, but the price was always a high one by comparison with that quoted above, and rose during the War to more than £30 per milligram of element Belgian production has brought the price down to £12, but the interests concerned have sold it for £10 per milligram where large quantities have been in question, and, on the other hand, they may charge £14, as stated by an official in a communiqué to the *Daily Telegraph* of May 25 Prof Lindemann's question remains a pertinent one, for whether it would pay to explore British territory for radium obviously depends on whether, with a find so rich as that in the Belgian Congo, production on a big scale would make a really big difference in the present selling price

THE retirement on May 20 of Mr W J Bean from the position of curator marks another milestone passed in the history of the Royal Botanic Gardens, Kew His loss to the establishment will be very great, for, in addition to his extensive knowledge of plants, he possessed considerable administrative ability and had the faculty of inspiring confidence and respect Mr Bean comes of Yorkshire stock and entered Kew as a student gardener in April 1883 His personality soon marked him out for advancement, and in 1888 he was given charge of the Temperate House Department His great opportunity came, however, in 1892, for in that year the late Sir William Thiselton Dyer began the reorganisation of the arboretum, and Mr Bean was transferred from the Temperate House to take charge of the work At that time the collections of trees and shrubs were weak in number of species, the general standard of cultivation was low, and really decorative subjects were not shown to advantage The work over a number of years was very arduous, but all who know the Kew arboretum of the present day will agree that Mr Bean is well repaid for his many years of hard work During the greater part of his career at Kew, Mr Bean has contributed to periodical horticultural literature He is also the author of "The History of the Royal Botanic Gardens, Kew" (Cassell, 1908), but is probably better known for his book "Trees and Shrubs Hardy in the British Isles" (John Murray, 1915), which has already been reprinted four times Mr Bean has for many years been a member of the Floral Committee of the Royal Horticultural Society, and the Society has awarded him the Veitch Memorial Medal and the Victoria Medal of Honour His services have on many occasions been requisitioned by public bodies at home and abroad, and in 1924 he was appointed a companion of the Imperial Service Order

THE Davy centenary celebrations at Penzance will take place on June 8, the arrangements having been made by the Royal Geological Society of Cornwall, the Royal Institution of Cornwall, and the Royal

Cornwall Polytechnic Society, the headquarters of which are respectively at Penzance Truro, and Falmouth At noon on that day the Mayor of Penzance, accompanied by members of the Town Council and of the three Cornish societies, will proceed to the Davy statue, upon which a wreath will be placed, luncheon will be served at the Pavilion at one o'clock, and at three o'clock a public meeting will be held in the same building, over which the Mayor will preside Addresses will be given by Dr J Symons, president of the Royal Geological Society of Cornwall, Mr J C Tregarthen, Sir Humphry Davy Rolleston, and Sir Ambrose Fleming, the last of whom will represent the Royal Institution of Great Britain, where for eleven years Davy worked and lectured so successfully An exhibition of Davy relics will be on view The Societies will be pleased to welcome anyone interested in the proceedings

THE seventh Annual Conference of the South Western Naturalists' Union was held at Torquay during Whitsuntide under the presidency of Dr F A Bather The Union covers the counties of Cornwall, Devon, Dorset, Somerset, Gloucestershire, and Wilts The meetings were held in the Pengelly Hall at the Museum of the Torquay Natural History Society, the president of which, Sir Francis Layland Barratt, received the guests The fine weather favoured excursions to Kent's Cavern, with Mr H G Dowie as guide, round Dartmoor, and to the chief points of geological interest in the neighbourhood of Torquay under the vigorous leadership of Mr G C Spence Sir John Russell delighted the members with an address on "The Conquest of the Waste Places", showing, chiefly by illustrations from the wheat belt of Canada and the irrigation of Australia and Egypt, how science has countered the pessimistic predictions of Sir William Crookes Mr F R Horne, of Seale Hayne Agricultural College, lectured on the succession of various woodland associations by grass land, and Mr J Walker read a paper on the moths and butterflies of the Torquay district The president's address, "Imagination and Fossils", showed how the controlled imagination can reconstruct the living form, habitat, and mode of life of vanished creatures quite unlike any now existing

ON May 15 a disastrous explosion, followed by fire, at the Cleveland Clinic, Ohio, was the cause of more than a hundred deaths among patients and staff The heavy mortality was due to gas poisoning, rescue work was much hampered by the dense brown choking fumes in the building, which, it was suggested, were bromine The first explosion appears to have occurred in the X ray department, and was probably due to the ignition of cellulose nitrate photographic film stored there In a statement made to Science Service, of Washington, D C, Dr Charles E Munroe, the chief explosives chemist of the U S Bureau of Mines, stated that, within less than a half minute after the explosion of such film, the resulting gases would be about one third carbon monoxide and one tenth oxides of nitrogen. These gases, produced in large quantities, spread through the building, and the brown fumes of the oxides of nitrogen were thought to be bromine The secondary explosion was probably due to the ignition of an explosive mixture of the carbon monoxide with air In investigations upon the effects of the fumes from smokeless powder explosions made by H C Knight and D C Walton at the Chemical Warfare Service's Edgewood Arsenal in 1925, it was found that experimental animals brought out of the explosion fumes, apparently unharmed, succumbed later to pulmonary œdema Since the fumes from smokeless powder are practically identical with those from cellulose nitrate film, this would account for the delayed poisoning effect shown by many of the victims

THE Linnean Society of London held its anniversary meeting at Burlington House on May 24, under the presidency of Sir Sidney F Harmer The following were elected officers of the Society for 1929–30 — *President* Sir Sidney F Harmer, *Treasurer* Mr H W Monckton *Zoological Secretary* Dr G P Bidder, *Botanical Secretary* Mr J Ramsbottom The Linnean Gold Medal for 1928–29 was handed to Dr J B Hubrecht, Counsellor of the Netherland Legation and son of the famous zoologist, for conveyance to Prof Hugo de Vries to whom the medal had been awarded in recognition of his great contributions to the advancement of botanical science In presenting the medal the president, Sir Sidney Harmer, paid tribute to the influence de Vries has had on biological thought since his thesis in 1870, particularly by his work on osmotic pressure, his theory of intracellular pangenesis, and his long series of studies on experimental evolution

LIEUT COL A T GAGE, having informed the Council of the Linnean Society of London that he wishes to resign his position as Librarian and Assistant Secretary at the end of October, Mr Spencer Savage has been appointed to succeed him Col Gage was formerly the Director of the Botanical Survey of India and Superintendent of the Royal Botanic Garden, Calcutta He entered the services of the Linnean Society as assistant to the late Dr B Daydon Jackson in 1924, succeeding him in office (though not with the special title of General Secretary) in 1926 Mr Savage has been clerk to the Society since 1911, with a break while on active War service He is well known to botanists by his bibliographical studies and to members of the Society as an authority on the Linnean collections and manuscripts

THE Hanbury Memorial Medal of the Pharmaceutical Society of Great Britain for "high excellence in the prosecution or promotion of original research in the Natural History and Chemistry of Drugs" has been awarded for the year 1929 to Prof Henry Hurd Rusby, professor of materia medica in the College of Pharmacy, Columbia University, New York The medal is purchased from a fund raised in 1876 to perpetuate the memory of Daniel Hanbury, F R S, who died in the previous year. His family name is perpetuated by the house of Allen and Hanbury, in which his father, Daniel Bell Hanbury, who survived him, was a partner His principal investigations were upon

the drugs of commerce of his time In 1927 the recipient of the medal was Dr T A Henry of the Wellcome Chemical Research Laboratories an authority upon the chemistry of the drugs and it is fitting that his successor to the award should be one who has specialised upon their botany and natural history So long ago as 1880 Prof Rusby accompanied an expedition organised by the Smithsonian Institution to New Mexico and Arizona where many new species of plants were discovered and in 1885 he was in Bolivia when some four thousand previously unknown species were found and described It was while exploring Para and Brazil that he discovered the plant *Cocillana* and first made known the medicinal properties for which it is now largely employed In addition to his explorations in Venezuela the rubber forests of the Madeira River and the forests of the lower Orinoco during the War he went on an expedition to Columbia in search of quinine yielding barks Nor did the passage of years blunt his zest for exploration for in 1922 he was in charge of the Mulford expedition which undertook a biological investigation of tracts of the Amazon basin In addition to the chair of materia medica he has the post of pharmacognosist to the Port of New York and with it the responsibility for the inspection of drug imports a task calling for ceaseless vigilance in the detection of ingenious adulterations He is at the moment engaged in a typically vigorous campaign to prevent the importation and use of decaying ergot from Russia Only twice before has the award gone to America—to J M Maisch in 1893 and to F B Power in 1913

AT the present time there is a great demand for underground cables suitable for carrying electric currents at very high voltages in towns and their neighbourhood A very large amount of experimental work in this direction has been carried out by cable manufacturers during recent years We learn from a paper by G Martinez which appears in the *Electrical Review* for May 24, that success is now almost assured by the invention of an oil filled cable In this cable there is inside the conductor a longitudinal duct carrying oil which is connected with reservoirs at the junctions at each end of a section When the conductors get hot the oil is forced by their thermal expansion into the reservoirs and when they get cool it is sucked back The conductor is insulated in the usual way, but owing to the diminished mechanical stresses on it the thickness of the insulation necessary is appreciably diminished The cable is armoured with hard brass strip over the lead sheath and is finally protected with waterproof cloth tape The working temperature of this oil filled cable can be much higher than that of the ordinary high voltage cable, and so it can carry a heavier load, while it can be safely laid directly in the ground There are no hollows inside these cables In ordinary cables the brush discharges that take place in a hollow are a frequent cause of breakdown It is claimed that it is possible to install underground cables of this new type up to pressures of 220 kilovolts We understand that two 132 kilovolt lines having a total length of 52 miles will be installed in London very shortly The installation is partly experimental but the makers have so much faith in the performance of their cables that they are taking the greater part of the financial risk

IT is expected that in a few weeks time the Brookmans Park Station the first high power station of the regional scheme of broadcasting in Great Britain will begin operation At first it will radiate only one programme but later on it is intended to radiate two simultaneously using different wave lengths It is probable that at first difficulties will be experienced by listeners especially those who are in the neighbourhood of Brookmans Park The foreign station listener in this district will have great difficulty in tuning out the local station The ordinary listener also may be unable to hear the programme from 5GB to which he has been accustomed The *Wireless World* for May 15 questions the wisdom of the policy of providing satisfactory crystal reception throughout Great Britain It suggests that this is probably being done at the expense of those who have invested in expensive valve sets These listeners have begun to think that they have a right to regard the continental stations as a source of entertainment however superior the quality of the home reception may be In the same paper there is an article on Getting ready for Brookmans Park describing methods of improving selectivity It is known theoretically that the selectivity of a receiving set can be improved either by diminishing the resistance of its tuned circuits or by increasing their number In the latter case a filtering effect is imposed on the incoming signals It is found in practice that the limit to which the resistance can be diminished is quickly reached We may increase the number of tuned circuits so as to filter out undesired signals but this would be expensive The most promising device is to use a tuned and variably coupled aerial transformer It is stated that in no other way can the selectivity of a set be so radically improved

EXTENSIONS of the building of the Royal Scottish Museum Edinburgh have permitted considerable expansion and rearrangement of the collections, while the Interim Report of the Royal Commission on National Museums by allaying the fear of fire permitted the progress of equipment and schemes previously held up Thus we read in the Director s type written Report for 1928 of the opening of a gallery of comparative ethnography, two new halls for natural history a civil engineering gallery and added exhibition space for minerals A beasts of prey hall and an architectural hall will be opened before long Still there are complaints of lack of space a printing press bought for exhibition has to be kept in store, while the consultation of reserve collections is hampered for want of storage accommodation. For all that, the collections grow the larger accessions include the Logan collection of British Lepidoptera, the late Robert Dunlop's fossils on loan from Dunfermline will be more accessible to students, a most useful collection of ceramics is lent by Lady Binning Among the numerous individual additions one notes the first specimen of the desert

wheatear to be found in the British Isles, the nest of a garganey duck—the first proof of its nesting in Scotland—and a self rescue apparatus presented by the Mine Safety Appliances Co of Pittsburg One learns without surprise that the museum grows in popularity Apart from the school classes and the lantern lectures to school children, the annual number of visitors has increased by 130,000 within the last eight years It is believed that visitors to the city are responsible for the numbers on week days, but that local people make up the large Sunday crowds Evening opening, so often clamoured for, appears here, as elsewhere, scarcely to warrant the additional cost of lighting and attendance

THE floating of globules of mercury on a water surface was described recently in letters to the Editor (Mar 16 and May 18) A correspondent reminds us that this effect was dealt with by Prof C V Boys in the second edition of his well known book on "Soap Bubbles and the Forces which Mould them" The description is as follows "One of the most beautiful bubbles of one liquid in another which can be produced is occasionally formed by accident If a basin of water containing a few pounds of mercury is placed under a violently running water tap the water and air carried down into the mercury cause mercury bubbles to form and float to the surface I have been able to float these into a second basin, where sometimes for a few seconds they look like shining balls of pure silver, perfect in form and polish When they break, a tiny globule of mercury alone remains, far more, however, than the liquid of a soap-bubble of the same size I have obtained mercury bubbles up to about ¾ inch in diameter M Melsens, who first described these in 1845, found the upper part to be so thin as to be transparent and of a slaty blue colour, a phenomenon which I have not noticed"

THE code devised at Strasbourg and adopted by international agreement for the telegraphic transmission of seismological information provides only for the data derived from the seismograms of individual stations (NATURE, Dec 22, 1928, p 968) There are occasions, however, when the sender of a report has already determined the epicentre of an earthquake and wishes to give its position For this purpose, a simple method has been adopted by the Meteorological Office and by the U S Coast and Geodetic Survey At the close of the report there will be added the word 'epicentre' and a group of five figures The first two figures give the latitude and the last three the longitude If the latitude is north and the longitude east, the number 2 is added to the middle figure, if south and east the number 4, if south and west the number 6, and if north and west the number 8 Thus, the figures 01779 would indicate that the epicentre is in lat 1° S, long 179° W

IN the January issue of the *Bulletin de la Société d'Encouragement pour l'Industrie nationale*, the Agricultural Committee of the society gives an account of the steps which have been taken during the past twenty years by the railway companies of France to encourage agriculture and the remarkable results obtained. The Paris Orleans company in 1903 began to distribute pamphlets, to organise lectures, discussions, and demonstrations, with the view of improving and intensifying production and increasing the possible markets for fruit, cereals, potatoes wines, cattle, milk, butter, cheese fowls, eggs, and honey Special officials were appointed to deal with the rapid transport of this produce to market The result of these efforts was remarkable in 1905 the company carried 250,000 tons of agricultural produce, and in 1907, 639,000 tons Other French lines have taken similar action with like noteworthy results

DR J H QUASTEL of Trinity College Cambridge, who is known for his work on reduction oxidation systems and for his studies of the activation of molecules by living organisms, has been appointed biochemist at the Cardiff City Mental Hospital

A VIOLENT earthquake was recorded at Kew Observatory commencing at 22 hr 51 min 19 sec G M T, on May 26 The epicentre is estimated to have been 4800 miles away but the initial impulse was not sharp enough to give any indication of the bearing

AT the annual general meeting of the Institute of Physics held on May 28, the following were elected to take office on Oct 1 next —*President* Dr W H Eccles *Honorary Treasurer* Major C E S Phillips, *Honorary Secretary* Prof A O Rankine Sir Ambrose Fleming, Sir James Jeans, and Sir Oliver Lodge were elected honorary fellows of the Institute

IT is announced in *Science* that the Agassiz medal for oceanography of the National Academy of Sciences of the United States has been awarded to Prof J Stanley Gardiner, professor of zoology and comparative anatomy in the University of Cambridge, and the Watson medal to Dr Willem de Sitter, director of the Observatory at Leyden and professor of theoretical astronomy in the University

THE fourteenth Annual Conference of the Museums Association will be held at Worthing on July 1-5, under the presidency of Sir Henry Miers The presidential address, on "Co-operation—the Association's Task", will be delivered on July 2, and will be open to discussion In connexion with the Conference there will be an exhibition of museum furniture and requirements The local secretary for the meeting is Miss Marian Frost, The Museum, Worthing

THE Rochdale Literary and Scientific Society has celebrated the jubilee of its formation by the publication of a volume of *Transactions* covering the years 1926-28, and by the presentation of his portrait to Dr J R Ashworth, in recognition of his services as honorary secretary since 1885 Dr Ashworth contributes a short article on "The Influence of Rain on Atmospheric Deposits", and an unusual and well-illustrated account of the very varied structure of the old pack horse tracks about Rochdale is given by Jas L Maxim

THE Council of the Association of British Chemical Manufacturers has decided to prepare and issue to its members a set of model safety rules for use in chemical

works The Works Technical Committee has been actively engaged for some months on the preparation of these rules, and a small booklet of provisional rules has now been presented to members of the Association A set of explanations of these rules is in preparation by the Association, the address of which is 166 Piccadilly, London, W 1

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in the Electrical Engineering Department of the Sunderland Technical College—The Chief Education Officer, 15 John Street, Sunderland (June 5) Assistant Examiners in the Patent Office—The Secretary, Civil Service Commission, Burlington Gardens, W 1 (June 6) A principal engineering inspector under the Engineering Inspectorate of the Electricity Commission—The Secretary, Electricity Commission, Savoy Court, Strand, W C 2 (June 8) Lecturers in, respectively, engineering, chemistry, and physics, and a mechanical workshop instructor and an electrical instructor, each at the Constantine Technical College, Middlesbrough—The Director of Education, Education Offices, Middlesbrough (June 10) An assistant lecturer in Nature study and horticulture at Stranmills Training College, Belfast—The Principal, Stranmills Training College, Queen's University, Belfast (June 10) A principal of the Government Commercial Institute, Calcutta—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S W 1 (June 12) An assistant lecturer in the Mathematical Department of the Derby Technical College—The Secretary, Education Committee, Becket Street, Derby (June 14) A director for the Harcourt Butler Institute of Public Health, Rangoon—The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S W 1 (June 15) A scientific assistant under the Imperial Bureau of Soil Science—The Director, Imperial Bureau of Soil Science, Rothamsted Experimental Station, Harpenden (June 19) An assistant lecturer in mathematics in the University of Sheffield—The Registrar, The University, Sheffield (June 19) A bacteriologist at the Antitoxin Establishment of the Metropolitan Asylums Board, Sutton—The Clerk, Metropolitan Asylums Board, Victoria Embankment, E C 4 (June 19) A senior plant introduction officer, an assistant plant introduction officer, an assistant plant pathologist, a weeds officer, an assistant mycologist, an assistant plant geneticist, and two assistant agrostologists under the Commonwealth of Australia Council for Scientific and Industrial Research —F L McDougal, Australia House, Strand, W C 2 (June 20) An assistant Government analyst, Hong Kong—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 (June 30) A research assistant in dyeing in the University of Leeds—The Registrar, The University, Leeds (July 1) A zoologist on the scientific staff of the *Discovery* Committee—The Secretary, *Discovery* Committee, Colonial Office, S W 1 (July 15) A senior secretary on the central administrative staff of London University—The Principal, University of London, South Kensington, S W 7 A lecturer in library routine and practical cataloguing in the School of Librarianship, London University—The Secretary, University College, Gower Street, W C 1 A laboratory steward in the physics department of the University College of Hull—The Secretary, University College, Hull

Our Astronomical Column.

THE TOTAL SOLAR ECLIPSE OF MAY 9 —*Harvard Announcement Card*, No 87, announces that Prof H T Stetson, who was stationed at Alor Star, Kedah, experienced some interference from high cirrus clouds, but succeeded in measuring the illumination of the corona. He found it equal to 0 15 candle at 1 foot, or to 1 candle at 2 58 feet As the brightness of the sun has been given as equal to 5000 candles at 1 foot, it is about 33,000 times as bright as the corona

A DOUBLE STAR OF THE TYPE OF GAMMA VIRGINIS —Mr C Luplau Janssen discusses the orbit of the star Burnham 12304 in *Mon Not. Roy Ast Soc* for March He shows that the distance, which increased from the discovery of the duplicity in 1832 up to 1910, is now decreasing, and that an approximate orbit can now be deduced That which he gives is of the type of Gamma Virginis with very large eccentricity (0 95) and very close approach at periastron, which he calculates will take place in 1976 The period is 177 2 years, and the semi major axis 2 81″ The hypothetical parallax is 0·089″ It is important to follow the star carefully during the approach to periastron.

HISTORICAL RECORDS OF METEORIC SHOWERS —Prof W J Fisher, of Harvard College Observatory, Cambridge, Mass., has issued a circular, and distributed it amongst astronomical and other scientific institutions, asking for old accounts of abundant meteoric displays He intimates that though many descriptions were found by Newton, Quetelet, Herrick, and others, there must be numbers of additional records which have never yet been brought into the light and suitably investigated That this may be accomplished, and that a thorough discussion of all the available results, ancient and modern, may be submitted to examination and deductions made, seem desirable It is therefore hoped that persons having access to ancient works containing accounts of long past meteoric exhibitions will search them out and send copies of them to the Harvard Observatory so that they may receive due consideration.

With new data gleaned from old catalogues and chronicles, and the whole comprehensively treated, there is no doubt that our knowledge might receive important additions of interesting kind From Russian and Japanese sources some useful details have already been received, and the research promises good results if the subject is amply worked up and supported as it undoubtedly deserves.

Of the display of Leonids in November 1766 nothing is apparently known more than mere rumours can convey Dr Dick says the meteors of 1799 were seen by all the inhabitants of Cumana, the oldest of whom asserted that the great earthquakes of 1766 were preceded by similar phenomena. Further careful inquiry might elicit important details.

Research Items

Food of the Great Horned Owl.—A short account of the more striking habits of this owl (*Bubo virginianus*) appears in the *Canadian Field Naturalist* for April. In the poplar savanna of Manitoba where the author, Ralph D. Bird, studied the owl, he estimated that one nesting pair was present in every square mile of suitably wooded country, the presence of good hunting grounds being apparently a decisive factor in the selection of the site. The birds when disturbed have been known to attack man, and the author describes a concerted attack upon himself which had serious enough consequences. An examination of 112 food pellets showed that as a staple diet rabbits headed the list, then followed voles, pocket gophers, ground squirrels, and occasional birds taken especially after the spring migration. The association of prairie and woodland mammals in the diet suggests a wide hunting range on the part of the owl. Although the nests were not far from farmyards, only one domestic fowl was found to have been taken, and game birds did not average as many as two per nest. The conclusion is that the bird is a decided benefactor to humanity, through its enormous destruction of rodents, which injure crops and are second only to fire as a factor in checking the spread of the forests.

The Genus Phellia.—Dr. T. A. Stephenson's account (*Trans. R. Soc. Edin.*, vol. 56, 1929) of the British species of *Phellia* fills a lacuna in our knowledge of British sea anemones. In 1858 P. H. Gosse collected from a 'rock called Proudfoot at the entrance to Wick Bay in Caithness', the original specimens of *Phellia gausapata*. The author visited this rock in 1926, and collected thirteen examples of the species, and has given an account of their external characters and internal anatomy. He has examined three other species which have been regarded as belonging to the genus *Phellia*, and shows that two of them—*P. murocincta* and *P. picta*—are Sagartias, and that the other—*P. brodricii*—should be placed in a new genus, *Cataphellia*. The genus *Phellia* is defined for the first time on a valid basis and its relationships determined; it is removed from the Sagartiidæ and placed in a separate family, the Phelliidæ—with *P. gausapata* as the type species. The patterns developed on the disc and tentacles in the Phellias and other sea anemones are analysed, and their value as an indication of relationship discussed, especially in respect of species the relationships of which are difficult to determine. The paper is illustrated by text figures and by finely executed drawings in colour which have been admirably reproduced.

Genetics of Primula Kewensis.—In 1899, *Primula Kewensis* appeared at Kew as a natural hybrid between *P. floribunda* and *P. verticillata*. The cross was then successfully made, but has never been repeated, the few plants obtained in later attempts being either like the mother (*floribunda*) or tetraploid *Kewensis*. The original diploid hybrid plants first bore seeds in 1905, producing the tetraploid form. Owing to errors in the early work on this form, it has long been a cytological and genetical misfit. In a paper by the late W. C. F. Newton and Miss C. Pellew (*Jour. of Genetics*, vol. 20, No. 3), which will become a classic, the various problems regarding its origin and genetical nature are solved, and it is brought into line with other cases in recent genetical literature. The fertile *P. Kewensis* is shown to be a tetraploid mutation arising in somatic tissue of the sterile diploid hybrid, and not due to a transverse fragmentation of the chromosomes as formerly supposed. Usually the diploid hybrid is highly sterile, but on the three occasions in which it is known to have set seeds, these gave rise to fertile tetraploid plants. The third lot of such plants grown at Merton was the largest, numbering 287 plants, of which 261 were of the ordinary tetraploid type, while the remaining 26 showed much variation, which was generally associated with the presence of 35 or 37 instead of 36 chromosomes. There is also variation in mealiness and shape of the leaves. Several other cases are now known in which a tetraploid form is produced in the crossing of two diploid species, but *P. Kewensis* differs from these in that the tetraploid condition first arises in somatic tissues. By crossing it with the diploid parents, various triploid or near-triploid forms have been obtained and studied. This paper is an excellent example of the necessity for cytological studies in the investigation of any complicated genetical situation, but various problems regarding the descendants of *P. Kewensis* remain to be attacked.

Sodium Accumulation and the Earth's Age.—In the *Am. Jour. Sci.* for April 1929, Prof. A. C. Lane directs attention to yet another source of error in this much discussed method of estimating geological time. It has been customary in estimating solvent denudation to take several analyses of the river water and average them to get the average composition, and then multiply this by the total run-off. This neglects the fact that generally speaking the greater part of the run-off of a river is in floods, and that in time of flood the amount of sediment is greater and of dissolved matter much less than when the river is normal or low. From work by W. D. Collins on the Colorado River and by L. Nys on the Meuse and the Ourthe, Lane deduces that it would not be safe to take the solvent denudation of the lands by river waters at more than five-eighths of that usually adopted (for example, by F. W. Clarke in his well-known "Data of Geochemistry"), and he thinks there is a fair possibility that it may be no more than two-fifths. Making allowance for other factors and for the slow denudation of small continents in times of peneplanation and marine transgression, it is not difficult to bring the figures for the age of the earth by solvent denudation into agreement with the longer periods obtained from the lead ratios of radioactive minerals.

Limestones and Limestone Soils of the East Indian Archipelago.—In *Communication* No. 14 of the Geological Institute of the Agricultural University of Wageningen, Holland, Prof. J. van Baren has presented in English the results of his investigations during the last thirteen years on the weathering of limestones and the formation of limestone soils in Java and other islands of the Dutch East Indies. Detailed qualitative mineralogical analyses are given for 21 rocks and for two mechanical fractions of 46 soils derived from them. Other soil data include colour by Lovibond's tintometer, mechanical analysis, hygroscopic coefficient, maximum water capacity, and reaction measurements by several methods. Full chemical analyses are given for a dozen soils and their underlying rocks. It is concluded that the properties of the soils are determined primarily by the composition of the limestone rock. Although the rainfall is important, the present knowledge of agricultural climatology is totally inadequate as a basis for the classification of soils and soil-forming processes. The analogies that have been drawn between the red limestone soils of the tropics and other red soils,

such as the Mediterranean *terra rossa* are strongly criticised The red colour shows nothing beyond the presence of some colloidal iron oxide of unknown origin and gives no evidence that the soil has been formed in a humid tropical climate It is claimed that the careful collection of facts must proceed for many decades before generalisations on the relation of soil to climate can have any value Prof van Baren appeals especially for detailed and systematic mineralogical research on the relation of the soil to the parent rock He has been able to distinguish minerals formed within the soil from those derived from the parent rock or introduced by the action of volcanoes water or wind The fuller study of such newly formed minerals should reveal some of the chemical processes within the soil Again it is shown that apatite is rarely present in either soils or rocks and cannot be the source of the phosphoric acid in these soils Prof van Baren s detailed notes photomicrographs and bibliographies on the minerals and organic remains identified will prove of great value in extending this type of work

REFRIGERATION CONSTANTS —Supplement No 65 to *Communications* from the Physical Laboratory of the University of Leyden contains reprints of the papers communicated by Drs Keesom and De Haas to the Institut International du Froid on the entropy temperature and total heat entropy diagrams of methane ethylene, nitrogen hydrogen and helium The whole of the experimental facts available have been used in constructing the diagrams and have been supplemented where necessary by thermodynamic relations and the law of corresponding states Copies of these diagrams may be obtained by those interested in refrigeration through the Institut International du Froid

DIFFRACTION OF LIGHT —The April number of the *Physical Review* contains a paper by Profs M E Hufford and H T Davis which is illustrated by a very beautiful pair of photographs of diffraction patterns These were produced by passing mono chromatic light from a small source through two circular holes and the one from the smaller aperture shows some seventy clear concentric rings in the original The radii of these have been measured up carefully and have been compared with the radii computed by an extension of the classical wave theory of diffraction by a circular aperture which was given by Lommel calculated and observed values are in good agreement As the authors point out an investigation of this nature would have been considered to be of purely academic interest a few years ago whereas at the present time it is of con siderable value in defining the regions in which wave theory and quantum theory are individually appli cable It is to be regretted that the detail of the photographs, exceptionally good as it is is insufficient to show the presence of some secondary fringes that should theoretically be present

BRIDGE STRESSES —The issue of the *Journal of the Royal Society of Arts* for May 3 contains the Trueman Wood lecture delivered by Sir J Alfred Ewing on the results of the work done during the past six years by the Bridge Stress Committee of the Depart ment of Scientific and Industrial Research It has been found that the passage of a locomotive over a bridge produces a deflection at the centre which oscillates between limits determined by the weight of the locomotive and the intensity of the hammer blow it strikes on the rails due to the movement of unbalanced parts of its mechanism Some of the lighter engines still in use weighing 15 tons per axle deliver a blow equivalent to a further 15 tons, when some of the more modern ones weighing 20 tons per axle only deliver a blow equivalent to a further 5 tons The subject is too complex to allow simple rules for the calculation of the stresses produced to be formu lated

ARTIFICIAL VERSUS NATURAL ILLUMINATION —In a paper on the cost of lighting industrial buildings which appears in the *Journal of the Franklin Institute* for February L L Holladay discusses some of the problems which arise when the electric light can be purchased at a price not exceeding about 0 7 of a penny In several cases he proves that artificial light is more desirable than daylight from the eco nomical point of view It is pointed out that natural light whilst costing nothing out of doors can only be delivered at a certain definite cost indoors The cost and maintenance of the windows and the lighting shafts has to be taken into account In the winter time the thermal losses through the windows are appreciable and increase the heating costs In making the comparison between the running and overhead costs of a building built for artificial lighting and one built for utilising the daylight also when possible it is assumed that both buildings have similar ventilat ing and heating apparatus It is assumed that for seven months of the year the inside of the building is maintained at 65° F and that the air is completely changed twice every hour The costs of washing the windows at least twice every year and cleaning the lamps at least six times are taken into account The heat loss due to the windows is generally offset by the saving they effect on the cost of the electric light The author recommends therefore, that industrial buildings should be built with simple side windows A windowless building requires a shaft about two feet wide for ventilation It is not economical to incur heavy expenses for lighting shafts or windows in the roof For dwelling houses we must have windows to enable us to see outside but in factories the glass of the windows is often obscured The conclusion is that when artificial illumination can be obtained very cheaply it would be well for the architect to take this into account when designing the building

THE TESTING OF PORCELAIN INSULATORS —The initial and maintenance costs of the large number of porcelain insulators required for high tension overhead distributing systems have made it necessary to apply rigorous tests to them before they leave the factory They are usually tested in accordance with the standard specification or with one which follows it very closely in essential details Specifications based on the individual opinions of consulting engineers are now very rare In a paper read to the Institution of Electrical Engineers on April 11, B L Goodlet dis cussed the technique of porcelain insulator testing The three basic electrical tests are the dry and the wet spark over voltage and the puncture voltage The fundamental mechanical and physical tests are for mechanical strength, ability to withstand a tempera ture cycle, and the test for porosity In addition, seven other tests, including corona tests, fog tests, and tests to determine 'fatigue under vibration, are sometimes specified The six fundamental tests are generally considered to be sufficient If the physical laws which govern the effects produced were better known it is highly probable that the required tests could be much simplified and appreciable economies effected The influence of the atmospheric humidity on the spark over tests is known to few physicists. Curiously enough, an increase in the humidity of the atmosphere up to about 75 per cent, at 40° C, in creases the voltage at which a flash occurs The wet

spark over voltage test is made with artificial rain As the rate of precipitation is increased the spark over voltage falls rapidly until a rainfall of about 3 mm per minute is reached after which a further increase in the intensity of the rainfall has little effect on the voltage at which spark over occurs The angle of the rainfall has a considerable effect on the result and so also has the resistivity of the rain which is a very variable quantity It is found that fog troubles only occur in districts where a considerable amount of solid matter in a finely divided state is suspended in the atmosphere

RADIO RECEPTION IN A TUNNEL —Some interesting experiments were recently made by Dr A S Eve of McGill University, and several well known radio engineers on reception in a tunnel on the Canadian Pacific Railway The results are printed in the *Proceedings of the Institute of Radio Engineers* for February The tunnel is $3\frac{1}{2}$ miles long and passes through Mount Royal near Montreal Preliminary experiments made in 1926 indicated that the penetration of radio waves into the tunnel was a function of their frequency If the wave length was less than 100 metres the radio waves died away within a few hundred feet of the mouth of the tunnel More exact experiments made in 1928 bring out the fact that the wires cables and rails leading into the tunnel play an important part in the reception by the receiving set The mouths of the tunnel were blocked and the cables were earthed The results showed that the effect of the cables and rails was also a function of the frequency The experiments show that more energy enters through the tunnel mouth than was at first suspected The effects of the rails and cables were due to a variety of causes which involve wave antenna effects and re radiation Curves are given showing graphically the results obtained and details are given of the geology of the region Amongst the conclusions arrived at are that short waves do not penetrate rock or soil to any appreciable extent that cables and rails conduct long waves better than short waves that insulated wires and cables act as wave antennæ and that a very appreciable amount of energy enters through the tunnel mouth Further work is required in a tunnel with no wires or rails leading into it

PULVERISED FUEL IN POWER STATIONS —In a paper read to the Institution of Electrical Engineers on April 18, Mr R A Chattock discussed the use of pulverised fuel in electric power stations He claims that as the result of the experimental work carried out during the last few years at the Birmingham electrical power station, it has been proved that the use of pulverised fuel gives a higher combustion heat efficiency in the boilers than is obtained by mechanical stokers He points out that for pulverised fuel equipment the capital cost is greater than for mechanical stokers, but, as boilers can be used of far greater capacity than those equipped at present with mechanical stokers, there is a considerable economy effected in the cost of boilers and boiler house In the second series of tests made at Birmingham, the equipment consisted of four large coal driers of the rotary type which were fired by small furnaces These driers reduce the total moisture in the coal from 20 per cent to 6 per cent without driving off any material part of the volatiles contained in the coal The dry coal was conveyed by elevators and conveyors to bunkers in the boiler house From thence it was fed to four large motor driven mills each capable of pulverising 12 tons per hour The mills are air swept and the fuel is caught in cyclone collectors and stored in bins over the boiler From these bins it is delivered by special feeders to the six burners installed in each boiler furnace Two of these boilers have been in operation for a year with a combustion heat efficiency of about 85 per cent These experiments have led the Birmingham Corporation to adopt boiler units having an evaporative efficiency of 200 000 lb of water per hour for the new Hams Hall Station Unit pulverisers will be used for the boilers each of which will have five mills four to run and one to be kept in reserve New developments are in progress but satisfactory results extending over several years have been obtained both in America and on the Continent

PREPARATION OF SUBSTITUTED DIPHENYLAMINES —The preparation of substituted diphenylamines is often a matter of some difficulty and it is therefore interesting to note that a new method is given by A W Chapman in the *Journal of the Chemical Society* for March As previously shown *N* arylarylimino aryl ethers [R C (OR″) NR] are converted quantitatively by the action of heat into acyl derivatives of the corresponding diphenylamines [R CO NR R″] and on treatment with alcoholic potash these acyl compounds are readily hydrolysed to the corresponding diphenyl amines in yields of about 80 per cent

SOLUBILITY OF IODINE IN SOLUTIONS OF HALIDES — The *Journal of the Chemical Society* for March contains an account of experiments carried out by Carter and Hoskins which appear to show that the solubility of iodine in solutions of halides is the result of a tendency to form polyhalides and the opposing salting out effect The latter effect is considerable with bromides and chlorides but negligible with iodides and with the halogen acids Attention is directed to the fact that in their investigation of the tri iodide equilibrium Brönsted and Pedersen used potassium chloride solution as solvent and assumed that all the dissolved iodine was present in the free state No allowance was made for the effect of polyhalide formation and hence the mass law expression deduced by Bronsted and Pedersen is incorrect The corrected value for the equilibrium constant in this case is approximately the same as when the solvent is water

BENZENE RING —The April number of the *Proceedings of the Royal Society* contains a full account of Dr Kathleen Lonsdale s investigation of the crystal structure of hexamethylbenzone $C_6(CH_3)_6$ which as was indicated in a letter from her to NATURE on the same subject (Nov 24 1928 p 810) is of great interest from the way in which it confirms current ideas of the structure of the benzene ring This particular molecule, unlike many other aromatic compounds, exists as a separate entity in the crystal, which is triclinic and easily deformed The X ray evidence is definite that the molecule is in the form of a ring and that its nucleus is similar both in size and shape to the six carbon ring of graphite The X ray measurements also show that the carbon atom of the methyl group lies in the plane of the benzene ring so that at least three of the valencies of the aromatic carbon atom must be coplanar There is unfortunately no new information to be had concerning the elusive fourth bond except that it must be disposed so as to give the ring as a whole a centre of symmetry, which seems to rule out Kekulé s static model with its three double bonds The carbon atoms in the methyl groups, as would be expected from their aliphatic nature, resemble the carbon atoms in diamond rather than those in graphite, the methyl group itself, to use Dr Lonsdale's analogy, acts towards X rays very like an electron shuttlecock, if we picture a single atom as a tennis ball

In the Yellowstone with Princeton [1]

By Prof O T JONES, University of Manchester

IN the issue of NATURE of Nov 5, 1927, Mr E B Bailey gave a brief account of the 'Summer School of Geology and Natural Resources', which has been organised by Prof R M Field, of the University of Princeton, N J I was privileged last summer to be the guest of the Summer School in a tour through some of the characteristic regions of the United States, my fellow guests being Mr W J Johnston, of the Canadian Geological Survey and Prof W A Parks, of Toronto

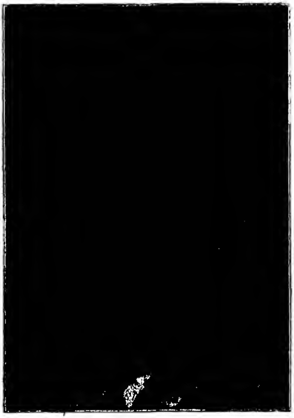

FIG 1 —Section of lower part of sediments near Red Rock Photograph by Prof O T Jones.

We started from Princeton on June 21, and returned on Aug 2, and in the course of the tour we visited the Yellowstone National Park

Within its area of 3344 square miles, this Park numbers many remarkable features, and among them the great canyon which has been carved by the Yellowstone River on its way to join the Missouri is one of the most interesting After leaving Yellowstone Lake the river winds through a flat floored valley before plunging in succession over the Upper Fall (108 ft) and the Lower Fall (309 ft), where the canyon commences About 20 miles lower down, the Yellowstone is joined by the Lamar, an important tributary flowing in a wide, flat floored valley

In the course of the 1926 excursion, Prof Field observed from near Artist's Point some sediments in the opposite wall of the canyon about half a mile below the Great Fall, and with a kinematograph camera and telephoto lens obtained a clear record of these deposits In August 1928 we visited the locality and examined the sections in detail Our examination led to the discoveries in regard to the remarkable history of the canyon which are briefly summarised below [2]

The sediments which Prof Field had previously observed lie in a narrow 'in and out' channel which passes behind a prominent pinnacle on the canyon wall known as the Red Rock, and consist of more than 187 feet of alternations of blue muddy silt, yellow sand, and conglomerate, the coarser deposits having a calcareous or tufaceous cement (Fig 1) The base of the channel lies about half way down the canyon wall, which at this point is about 800 feet high Dr Elwyn Perry and other members of the Summer School observed also a small thickness of sediments within 50 ft of the bottom of the canyon and within about 100 yards from the foot of the Great Fall, and one of us noticed on the west side of the canyon, where it is drenched by the spray of the fall, a patch of blue stratified material which appeared to be similar to the silt near the Red Rock On our return to the east we discovered that this exposure had been visited nearly sixty years ago by Dr A C Peale, during the preliminary survey of the Park by F V Hayden and his assistants Dr Peale described this material as a blue mud, and there is little doubt that this and the sediments low down on the opposite side of the canyon are relics of the same series as that more fully preserved near the Red Rock We found, too, that the east wall of the canyon, between the Upper and the Lower Fall, is composed in large part of cross bedded sands capped by a tough conglomerate with tufaceous cement

According to the prevalent opinion, the canyon was eroded in postglacial times, and it has been regarded as evidence of the enormous amount of denudation that has taken place since the Glacial Epoch Colour was lent to this view by the distribution of the terraces which surround the Yellowstone Lake and extend down into the Hayden Valley towards the Yellowstone Falls These terraces are composed in part of resorted glacial deposits which occur around the Yellowstone Lake and in the Hayden Valley, and are therefore clearly of postglacial date It appears also that the conglomerate between the Upper and Lower Falls has been interpreted as an extension of these terrace deposits, and it was so regarded by E De Martonne, who figured the section in the *Annales de Geographie* (vol 22, 1913, Pl II B, facing p 136). This was also the interpretation adopted by Mr W H Holmes in his report on the geology of the Park attached to Hayden's 12th Annual Report on the Territories, 1878 As this conglomerate occurs on both sides of the present canyon, it was argued that the canyon must be of later date than the Yellowstone Lake terraces, and therefore postglacial Our examination disclosed, however, that a pre existing canyon had been at some period filled to the brim with sediments, and the relation of these to the glacial deposits seemed to indicate that not only the erosion of the canyon but also its subsequent filling had taken place before the advent of the glacial period, and that the canyon was a much older feature than had been previously supposed.

The fine muddy silts which form a considerable proportion of the sedimentary succession in the canyon recall lake deposits, and the occurrence of several

[1] Based on a lecture entitled "The History of the Yellowstone Cañon (Yellowstone National Park), U S A delivered before the Geological Society of London on Jan 9

[2] A more detailed account appears in the *Amer Jour of Science*, March 1929

layers of silt following immediately upon conglomerate inevitably suggests the establishment of lakes in the canyon at successively higher levels, and their subsequent filling with deposits beginning with fine sediments and ending up with coarse sands and gravels. Such lakes could only come into existence if the canyon had been dammed below this point subsequent to its erosion. What then was the agent which impounded these lakes in the canyon? The study of the geological maps in the United States Folio (1896) suggested the possibility that great flows of lava had entered the Yellowstone Valley from the north from the direction of Gardiner, and had flowed against the direction of the drainage into the Lamar Valley and the canyon. On the geological map of the Canyon and Gallatin Sheets several small masses of basalt and trachytic rhyolites have been mapped the relation of which to the flanks of the valley suggests that they are relics of flows which must originally have been of wide extent and filled the lower Yellowstone Valley to a depth of more than 1500 ft.

The suggestion that arises naturally from the study of the geological map is, however, contrary to the interpretation of certain of these flows which is embodied in the description of the Folio which was published in 1896. The summary in the Folio of the geological and volcanic history of the region is due to Arnold Hague. The igneous rocks were described by Iddings in Monograph 32, Part II, and in this monograph reference is made to the account of the physiography of the Park by Hague in Monograph 32, Part I. It appears, however, that this part of the monograph has never been published, and we are dependent upon the brief summary of the geology of the Park which accompanies the folio.

Hague's view of the volcanic history of the Park is embodied in the following table:

Pleistocene	Glacial drifts, etc.
Neocene	Basalt
	Rhyolite
	Basalt
	Canyon Conglomerate
	Basalt
	Andesitic flows and breccias
	Trachytic rhyolites
	Basic breccias
Eocene	Acid breccias
	Pinyon Conglomerate
	Unconformity
Cretaceous	Laramie formation

Fig. 2.—Section near Tower Falls showing two basalts with intervening conglomerate resting on andesitic breccias. Photograph by Dr. M. B. Hodge.

The rocks to which special attention is directed are the trachytic rhyolite which was assigned to a period during the accumulation of the Neocene volcanic breccias and the two basalt flows with the intervening canyon conglomerate which were believed to underlie the rhyolite. Since the canyon conglomerate yielded fragments of bones which were identified by Prof. O. C. Marsh as belonging to the skeleton of a fossil horse of Pliocene time the rhyolites must, according to this view, have been erupted at a late stage in the Pliocene period and the erosion of the canyon through the rhyolites must have occurred at a still later period. As this interpretation of the relation of the basalts, canyon conglomerate and trachytic rhyolite to the main rhyolite seemed to be at variance with the distribution of these rocks as shown on the geological map, Prof. Field and I decided to investigate this problem further.

Fig. 3.—Drawing of section near Tower Falls by W. H. Holmes. From Hayden's 12th Annual Report of the Territories, 1878.

In various places on the route between Gardiner and Camp Roosevelt, which lies near the junction of the Yellowstone and Lamar Valleys, there are masses of

basalt and trachytic rhyolite which are obviously perched on narrow shelves on the valley sides and their situation is such that these lavas must have been poured out on to the floor of a pre existing valley

The most convincing evidence of the relation of the basalts to other rocks in the canyon is, however, obtained near the Tower Falls south of Camp Roosevelt, where Tower Creek drops into the Yellowstone Above Tower Falls the 'canyon' is a fairly wide valley with terraced slopes Near Tower Falls the river swerves to the west and enters a very narrow canyon with almost precipitous walls of andesitic breccia which has been eroded into a striking series of pinnacles or 'needles' This is the 'second canyon' of earlier observers, and is probably of postglacial origin Its rim is formed by a sheet of basalt with remarkably regular columnar jointing, this sheet is easily accessible on the road on the west side, where it rests on a conglomerate On the east side the basalt overlies a conglomerate about 100 feet thick, underneath which is another band of columnar basalt (Fig 2) This striking section is among those drawn by W H Holmes, and a comparison of recent photographs with the sketch made more than fifty years ago demonstrates the remarkable accuracy of that artist (Fig 3)

If the east side of the second canyon be examined for about a mile below Tower Falls the upper basalt can be traced as a continuous band, but the lower basalt is only present at the north end and the south end, and is not visible in the intervening space, where also the conglomerate is reduced to about one quarter of its thickness (Fig 4) This behaviour of the lower basalt and the conglomerate as seen from the west side of the canyon is due to the fact that the lower basalt and the lower part of the conglomerate pass behind a screen of the andesitic breccias which form the lower wall of the canyon In other words, the basalt and conglomerate series occupy an old valley, and the existing canyon has been eroded on the flank of that valley through the basalts and conglomerate into the underlying andesitic breccia On the roadside south of Tower Falls the flank of the old valley stands at a still higher level, so that only a few feet of conglomerate separate the upper basalt from the andesitic breccias, ultimately it cuts out from below the upper part of the conglomerate, and the upper basalt then comes to rest on the andesitic breccias that formed the flank of the old valley There is here convincing evidence that the basalts and conglomerate have filled in a valley which formerly continued in the line of the wide part of the canyon above Tower Falls

FIG 4 —Section in canyon below Tower Falls showing upper basalt and upper part of conglomerate resting on andesitic breccias Photograph by Prof O T Jones

In the same line about two miles farther north stands the striking feature known as Junction Butte The capping of the butte is basalt, while the lower part of it is composed of trachytic rhyolite Both here and in other places farther down the canyon, the relation of the basalts to the trachytic rhyolites appears to indicate that these two rocks belong to the same general period of eruption A narrow outcrop of trachytic rhyolite is in fact represented on the geological map directly on the course of the buried canyon more than a mile south of Junction Butte

Holmes has also given a drawing of a sheet of basalt lying on conglomerate about half way down the wall of the canyon, four miles above Tower Falls Again, basalt overlying in places the canyon conglomerate is mapped on the floor of the wide Lamar Valley for a distance of 20 miles above Junction Butte

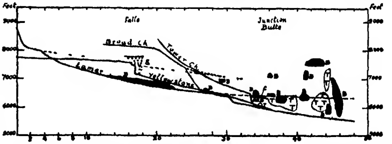

FIG 5 —Longitudinal profiles of Yellowstone and its principal tributaries showing also the lava flow relics in relation to the profiles The black masses labelled B are basalts, the areas marked T are trachytes C indicates the canyon conglomerate near Tower Falls and S the sediments near the Yellowstone Falls.

There is no doubt, therefore, that lava flows entered the Lamar Valley and penetrated for several miles into the canyon, and that near Tower Falls this filling of the older canyon is by a fortunate circumstance still preserved, and it confirms the suggestion made above that the damming of the canyon may have been due to lava flows

If we inquire further into the distribution of the basalt relics that now lie in the flanks of the lower Yellowstone canyon—the 'third canyon' of previous

authors—we find that they rise in places to a level of between 7800 ft and 8000 ft, whereas the highest level attained by the sediments near the Yellowstone Falls is a little above 7800 ft The lava surface stood, therefore at a height sufficient to cause the filling of the upper end of the canyon to its very brim

We turn now to a consideration of the longitudinal profile of the Yellowstone River and its principal tributaries The Lamar Valley profile shows clearly three cycles of erosion—the earliest cycle is only represented by a portion near the head of the valley the second cycle extends down to within about five miles of Junction Butte where the valley of the third cycle begins In the Yellowstone there are three or perhaps even four cycles represented (Fig 5)

There is some doubt whether the part of the valley above the falls or the portion between the two falls should be assigned to the first cycle but it is immaterial in this connexion The main canyon belongs clearly to the second cycle and the third canyon to the third cycle, the second canyon being probably due to a later and postglacial cycle The greater part of Tower Creek pertains to the second cycle and at present hangs conspicuously above the second canyon The profile of Broad Creek which enters higher up the main canyon on the east side is related as to its middle portion to the first cycle and as to its lower portion to the second cycle Evidences of these cycles can also be traced in the transverse profiles of the various canyons If now we project on to these profiles the outcrops of the basalt and trachytic rhyolite relics we find that these descend at their lower ends to within about 100 feet of the river level in the third canyon and at their upper ends attain increasingly greater heights downstream

It follows that these lava flows entered the canyon when the third cycle of erosion was far advanced

Since the main canyon which pertains to the second cycle was eroded through the rhyolitic rocks it is obvious that a great interval of time separates the eruption of the rhyolites and that of the valley basalts which occupied the valleys of the third cycle These considerations render it unthinkable that the basalts and conglomerates near Tower Falls were in existence prior to the eruption of the rhyolites Moreover, there is reason to believe that the surface of the rhyolites had been reduced by prolonged erosion to a peneplain before the initiation of the first cycle of erosion The canyon cycle of erosion thus commenced a very long time after the eruption of the rhyolites, and as a result it is assumed, of successive uplifts, rejuvenation brought about the erosion of the main canyon and later of the third canyon While the latter cycle was far advanced, eruptions of basalt and trachytic rhyolites dammed the canyon and near the falls it was filled to the brim with sediments Erosion was thus arrested and the canyon became a fossil canyon

Since the lava eruptions of the Upper Pliocene the greater part of the lava dam has been removed, leaving only relics here and there as witnesses to the former extent of the lava floods The erosion of the dam allowed of the removal of the sediments and the resurrection of the canyon. The original canyon is therefore an extremely ancient feature, dating probably from the Middle or Lower Pliocene

In conclusion, it gives me great pleasure to put on record the remarkable accuracy of Mr Holmes's observations and his deductions made during the short period when he was examining the geology and physical features of the Park more than fifty years ago

Mineral Industry of New South Wales

THE Department of Mines of New South Wales has issued a very useful volume entitled The Mineral Industry of New South Wales written by E C Andrews and the staff of the Geological Survey and edited by F S Mance Under Secretary for Mines, who contributes two introductory sections Such a work was long overdue in 1901 a similar work entitled The Mineral Resources of New South Wales was produced by Mr Edward F Pittman at that time Government Geologist of New South Wales This book contained a mass of useful information and was in such demand that it has been out of print for many years When Mr Pittman's book was written the most important mineral products of New South Wales were gold copper and tin whereas to day lead zinc and coal are of far greater importance

The general trend of mineral production in the State has been markedly upwards and the value of these productions has risen tremendously The total value of the metals and minerals produced in the State of New South Wales to the end of 1927 is given as close upon 445 million pounds sterling out of which the decade 1918 1927 has contributed no less than 155½ million pounds sterling and there is every evidence that the upward trend is likely to continue

The present work covers satisfactorily the whole field of mineral production it commences with a few brief sections of a general character followed by a description of the occurrences of metals and metallic ores ranged in alphabetical order the only serious exception to this statement may be found in the fact that the four metals silver lead zinc and cadmium are all lumped together mainly for the reason that the ores of these metals are generally found intimately associated Of course by far the most important deposit of these minerals in the State of New South Wales is in the Great Broken Hill deposit one of the most important in the world not only on account of its magnitude, but also because the intimate admixture of ores occurring there has stimulated the ingenuity of inventors to devise processes which have since been applied successfully to deposits in all parts of the world

The third part of the book consists of a description of the occurrences of non metallic minerals also arranged in alphabetical order The term non metallic' minerals is used in its ordinary acceptance compounds of the elements which the chemist would speak of as metals of the alkalis and the alkaline earths being in accordance with ordinary everyday usage spoken of as non metallic substances The work is a very complete one and will no doubt satisfactorily fulfil its object of presenting to the reader a brief but accurate and authoritative description of the mineral wealth of New South Wales

University and Educational Intelligence

CAMBRIDGE —The Director of the Observatory has, with the consent of the Vice Chancellor, reappointed Dr W M Smart of Trinity, as chief assistant at the Observatory for five years

The Sudbury Hardyman Prize at Emmanuel College, offered to a graduate of less than M A standing, has been awarded to A H Wilson for a dissertation on 'Quantum Mechanics Special dissertation prizes have been awarded to C B Allsopp (physical chemistry) and J G A Griffiths (chemistry)

SIXTY NINE 'land grant' colleges and universities have been established in the United States under a series of Acts, beginning in the year 1862, for the granting of land for financing education in agriculture

and the mechanic arts The sixtieth annual report of the Bureau of Education on these institutions (*Bulletin* No 14, 1928) shows that from small beginnings they have by degrees become leading factors in higher education, enrolling, as they do, more than two fifths of all the university and college students in the United States Land grants now provide only a small fraction of their total revenues In 1926-27 the land grants and other federal aid amounted to only four million dollars out of receipts amounting in the aggregate to 137 million dollars Twenty six of them with receipts amounting to 78 million dollars are now combined land grant colleges and State universities Agriculture attracts only a small and diminishing number of students In 1927 only seven and a half per cent of the resident students in the 52 institutions attended by white students were pursuing agricultural courses, while twenty per cent and five per cent were students of engineering and home economics respectively In the 17 negro colleges, out of 7018 students enrolled in regular courses, 965 were studying agriculture, 1672 trades and mechanic arts, and 1630 home economics A comprehensive national survey by the Bureau of Education of the land grant colleges is now in progress

The annual conference of the Association of Teachers in Technical Institutions was held in Liverpool during the Whitsuntide holiday In his presidential address, the new president, Mr A E Evans, of the Battersea Polytechnic, pursued two main arguments which deserve special and serious attention, particularly in view of the educational reorganisation which is now proceeding The first was that local and regional inquiries into the question of education and industry, and the setting up of occasional committees such as those for engineering and salesmanship, are not, in themselves, sufficient to solve the problems which have already received the attention of such national inquiries as those made by the Malcolm and Emmott Committees Both these bodies saw the necessity of establishing a small national committee the duty of which would be to co ordinate local and regional effort and to act as a clearing house for suggestions made towards the solution of the many problems now being presented No concerted national action is possible without such a body, and, until it is set up, only piecemeal attempts at advance can be made While welcoming the recently appointed committee on salesmanship, Mr Evans insisted that production is the first necessity if our industrial problems are to be solved, new methods and new processes must be developed and devised, and new links made between the operations underlying production and the creation of power Mr Evans's second argument was one with which readers of Nature are already familiar In spite of the lip service paid to the new conception of education with which our scientific and industrial civilisation is concerned, there is still a great tendency for educationists to regard with distrust schemes and curricula which deal with the application of science to industry, and to preserve, therefore, an attitude of remoteness from the everyday world They forget, in their adoration of poets and artists and philosophers, the scientific workers, engineers, builders, and architects from whom technical institutions are handing down the means of lightening the burdens of mankind Among resolutions dealt with by the Conference was one on the position of the junior technical school in the educational system It was the result of a lengthy inquiry made by the Association which included special attention to the way in which these schools have been able to satisfy the demands of industrialists for employees able to adapt themselves to the changing needs of industry

Calendar of Patent Records

June 1, 1818—The first French aeronautical patent was that granted to P C Verger on June 1, 1818, for a dirigible airship The ship, in the shape of a fish, was propelled by manually operated fans and was caused to rise or descend by a weight which could be moved along the length of the ship According to the patent specification, successful flights had been made in which the airship had been driven and manœuvred with ease, but there is no other record of these flights The ship bears a close resemblance to that proposed by Pauly and Egg, which had been patented in Great Britain three years earlier

June 4, 1872—Vaseline was patented in the United States by R A Chesebrough, of New York, on June 4, 1872, the word being used for the first time in the specification of this patent It was decided in the British courts that the word became one descriptive of the substance on the lapse of the patent rights in Great Britain, and could not be registered as a trade mark

June 5, 1787—William Symington's steam engine, which was patented on June 5, 1787, was originally intended for a road carriage, but its chief claim to importance lies in the fact that it was used by Patrick Miller in the first practical attempts at steam navigation in Great Britain, a small double hulled paddle boat, with the paddle wheels placed between the two hulls and originally driven by man power, being successfully propelled by it on Dalswinton Lake in 1788 In the following year a larger vessel of the same type was propelled on the Forth and Clyde Canal at a speed of 5 miles an hour, but after a few trials the experiments were abandoned, and were not resumed until the *Charlotte Dundas*, with a new engine, was launched in 1803

June 5, 1854—James Bowman Lindsay was the first to propose a definite scheme for connecting Britain and America by wireless telegraphy His invention for a method of transmitting telegraphic messages by electricity through and across water without submerged wires, the water being made available as the conducting medium, was patented on June 5, 1854 Signals were successfully transmitted across the River Tay (a distance of about ½ mile), and Lindsay calculated that with two stations, one situated in Cornwall and one in Scotland, and two correspondingly disposed stations in America, communication could be obtained across the Atlantic

June 7, 1821—The use of the rocket for the killing and capturing of whales was patented by Sir William Congreve and J N Colquhoun on June 7, 1821 The specification includes a description of the rocket-bomb, which was afterwards re invented in America and became one of the most deadly weapons used in whale fishing

June 9, 1840—It was Thomas Edmondson who first thought of issuing railway tickets in their present form His patent, dated June 9, 1840, had for its object the printing of "cardboard tickets in such a manner that each ticket should bear a progressive number or figure and thus, by being delivered in successive rotation to the passengers, the way bills would be readily made out, a most perfect check could be kept upon all clerks or other officers engaged in receiving money, and a daily or weekly return could be readily made merely by noting the opening and closing numbers of the tickets delivered" The invention comprised a printing machine for printing the cardboard blanks with the proper letterpress and successive numbers, and a dating machine which was put into operation by pushing the end of the ticket into the apparatus.

Societies and Academies

London

Linnean Society, May 2.—**H. H. Haines**: Some aspects of the New Forest, with special reference to the changes wrought by direct or indirect human agency. The poverty of the reproduction of trees and the poor aspect of the young growth is due chiefly to the grazing, browsing, and trampling of domestic animals, as also is the entire composition of parts of the vegetation. The first evident results of excessive browsing is the gradual reduction of the underwood to thorny, prickly, or otherwise distasteful species. The herbaceous flora and fauna are affected by grazing, but also very largely by collectors and the direct action of man in clearing and draining. The impoverishment of the fauna and flora of the open heaths is partly accounted for by too much and too severe burning.—**F. S. Russell**: The Great Barrier Reef Expedition and its aims. The expedition is based on Low Island, forty miles north of Cairns, North Queensland, and situated eight miles from the mainland and midway between the coast and the great barrier itself. The shore party is undertaking an ecological survey of the island and adjacent barrier reef, studies in the growth of coral, and life histories of economic products, and experimental work on the feeding habits of corals are being carried out in the laboratory. The sea work entails a complete seasonal survey of the chemical constituents of the sea water and of the plant and animal plankton, together with physical observations such as temperature and transparency (see NATURE, Jan. 19 and May 18).—**G. Tandy**: The vegetation of the Great Barrier Reef. There is a mangrove swamp to windward (with *Rhizophora mucronata* the dominant) and a more or less vegetated cay of coral sand to leeward as is found on many islands north of Low Island. The formation depends on the South East Trade Wind, which is fairly constant here from April to November. In early morning it will be at S.S.E. and light, but as the day goes on it will shift to E.S.E. or even E. and freshen. The heaviest seas are thus on the north side of the mangrove island, and the drift of the coral shingle is driving the mangrove back. On the lee side of the swamp, however, they are extending in a westerly direction.—**H. W. Pugsley**: A revision of the British *Euphrasiæ*. The British species of *Euphrasia* were first studied by the late F. Townsend, who published a monograph in 1897, adapted from the larger work of Prof. E. von Wettstein of the preceding year. The relationship of the generic subdivisions, as given by Wettstein, is open to criticism.

Paris

Academy of Sciences, April 22.—**Jean Baptiste Senderens**: The preparation of the ether-oxides of the aromatic alcohols by the catalytic action of the alkaline bisulphates. Benzyl alcohol and phenylethyl alcohol are readily converted into the corresponding ethers by the action of sodium bisulphate. Mixed ethers, such as $C_6H_5 - O - CH_2(C_6H_5)$, can be prepared in a similar way.—**J. Herbrand**: Some properties of true propositions and their applications.—**Bertrand Gambier**: Moutard equations with quadratic integrals.—**Ragnar Frisch**: A general formula of the mean.—**Arnaud Denjoy**: A class of analytical functions.—**H. Mineur**: The rotation of the local (star) cluster.—**P. Lejay**: A chronograph recording the ten thousandth of a second and its application to the measurement of the irregularities of astronomical pendulums. A development of the method described in an earlier communication for recording the passage of a pendulum through the vertical without using contacts.—**J. Barthoux**: Badakchan. An outline of the physical and geological features of this Afghan province.—**L. Décombe**: Electrified spherical pellicles and the Stark effect.—**Henri Chaumat**: The calculation of electrostatic machines.—**J. Vuillermoz**: The reversible electromotive force of electrolysis.—**H. Weiss** and **E. Vellinger**: The measurement of the interfacial tension between mineral oils and aqueous solutions. The influence of the degree of refining and of the degree of alteration of the oils.—**S. Piña de Rubies**: The arc spectrum of samarium. Measurements made at the normal pressure between 2750 A. and 2200 A.—**R. Soulillou**: The separation of the various spark spectra of antimony. The spark lines of antimony can be split up into three groups, probably Sb II., Sb III., and Sb IV.; the last two named are perfectly homogeneous, but the first, which is rich in lines, appears to consist of two sub-groups.—**D. Chalonge** and **M. Lambrey**: The continuous spectrum of the hydrogen tube. The influence of the following variables on the intensity of the continuous spectrum of hydrogen has been studied: the pressure of the hydrogen, the intensity of the discharge current, the dimensions of the tubes. The results suggest that it should be possible to use these tubes as standards of intensity in the ultra-violet.—**F. Joliot**: A new method of studying the electro-chemical behaviour of substances in very dilute solution. The velocity of deposition of the substance under examination is determined by measuring the increase in the optical density of a gold or platinum electrode transparent to light, a photoelectric cell being used for the light measurement. Details are given of the determination of the potential of the deposit of bismuth on a gold electrode, the quantities deposited being less than 10^{-8} gm.—**E. Rinck**: The equilibrium in the liquid state between potassium, sodium, and their bromides. The law of mass action, $(Na)(KBr)/(K)(NaBr) = c$, has been verified, and for temperatures from 900° C. to 1000° C. the constant c does not vary appreciably with the temperature. From this it follows that thermal effect of the reaction $Na + KBr \rightleftharpoons K + NaBr$, which at the ordinary temperature is −9.5 cal., is nearly zero at 800°–1000° C.—**F. Bourion** and **Ch. Tuttle**: The cryoscopic determination of the molecular equilibria of resorcinol in aqueous solutions of potassium chloride.—**Jean Calvet**: The corrosion of aluminium. Three specimens of aluminium were used in these experiments, one purified by Hoopes method (99.94 per cent Al), and two commercial metals (99.75 and 99.18 per cent Al). The extra pure aluminium (Hoopes) showed a marked increase of resistance to attack by solutions of hydrochloric, nitric, sulphuric, and phosphoric acids.—**Jean Lugeon**: A method of investigating the atmosphere by means of the disturbances of the electromagnetic field at the time of the passage of a crepuscular band.—**A. P. Dutertre**: The discovery of fossil bones of fishes in the Devonian of the Boulonnais. An account of a new species of *Ganorhynchus* (*G. Rigauxi*) found in the limestone of Ferques at Beaulieu (Pas de Calais). This is comparable with that which has been described and figured by R. H. Traquair under the name of *G. Woodwardi*, and appears to be the only representative of the genus *Ganorhynchus* in Europe.—**A. Paillot**: Bacterial symbiosis and humoral immunity in the Aphides.—**Armand de Gramont**: The application of binocular vision to fixing direction.—**Jean Timon-David**: The action of bromine on insect oils. Figures are given for the hexabromide figure (Hehner and Mitchell method) of several insect oils, and a rough classification is attempted.—**H. Wünschendorff** and **Ch. Killian**: New observations on the

metabolism of *Ustulina vulgaris* —Mme Phisalix Some comparative properties of antirabic sera from vaccinated animals and natural antirabic sera

GENEVA

Society of Physics and Natural History, Mar 7 —**P Balavoine** Observations on ice The water from melted ice is always slightly turbid, this is not a sign of impure water, but is due to the calcium salts crystallised during the solidification failing to redissolve Ice, moreover absorbs ammonia from the surrounding air and water from melting ice may contain ammonia without the original water having been contaminated —**Ed Parejas** Geological observations in Corsica (3) The red deposits of Caporalino This formation occurs at the base of the Neojurassic limestones of Caporalino The latter are mixed with thin layers at their base In the absence of any characteristic fauna, there are as good grounds for correlating the red deposits of Caporalino with the red Oxfordian Argovian of the median Prealps as with the Upper Cretaceous all the more that they appear to lack the Foraminifera usual in the Upper Cretaceous —**A Liengme** The effect of intracardiac injections of adsorbent carbon in the guinea pig and white rat Intracardiac injections of carbon in the form of Indian ink in suspension in physiological serum are innocuous Intracardiac injections in doses of 4 milligrams or more per kilogram of live weight of Merck adsorbent carbon, in suspension of 1 per cent in physiological water cause immediate death Smaller doses produce total loss of muscular tone with clonic shocks in the posterior limbs After several hours of severe discomfort the animal returns to its normal condition Doses of Merck carbon eight times the lethal dose are innocuous if first mixed with a sufficient quantity of fresh human or guinea pig serum **L W Collet** and **Ed Paréjas** The geology of the Hockenhorn The unfolding of the Morcles Doldenhorn nappe has produced a crystalline wedge which has broken its sedimentary covering has scraped it in part, and has even penetrated the opposite side of the layer —**L W Collet** and **G Rosier** A new crystalline wedge in the Inner Faflertal (Lotschental) By the discovery of a new crystalline wedge in the Inner Faflertal the authors point out a correction required in the geological map of the Jungfrau of L W Collet and Ed Paréjas **G Rosier** A granitic mylonite of the Baltschiederlucke, the Bietschhorn massif There is at the Baltschiederlucke a zone of granitic mylonite connected with a plane of over lapping The mylonite contains lenses of crystalline schist of unknown origin, it is composed of albite and microcline cemented by a fine material, consisting for the most part of crushed quartz The microcline, not twinned, can only be identified by Fedorof's method —**A Falconnier** The stratigraphy of the Sequanian in the anticlinal chain of Noirmont, Creux du Cruaz near Saint Cergues The Sequanian there comprises three divisions (1) The lower, with marls and limestones containing *Astarte vocetica*, *Perisphinctes Streuhensis*, *P Fontannesi*, 35 metres, (2) middle reef facies, 60 metres, (3) upper, limestone marl with *Perisphinctes inconditus*, and *P Lothari*, 20 to 30 metres It corresponds with the horizons of the Geissberg, Wangen, and of Baden below the Argovian of the Jura It is defined by zones with *Peltoceras bimammatum* and *Perisphinctes Achilles* of Haug —**J Pilloud** The presence of the upper Lias, the Gault and the Barremian at Voirons (Préalpes externes, Haute Savoie) The discovery of fossils has enabled the author to determine the presence at Voirons of the Gault (zone with *Leymeriella tardefurcata*), of the Barrémian (limestones with Desmoceras), and of the upper Lias (zone with *Lioceras opalinum*) —**R Wavre** The moments of inertia of the terrestrial ellipsoid The author gives a new formula for the constant of precession of the equinoxes, and he extends that of Poincaré to the whole of the equipotential surface exterior to the planet

ROME

Royal National Academy of the Lincei, Feb 17 —**G Scorza** Riemannian matrices With the help of the theory of algebra, together with the results already obtained by the author concerning Riemannian matrices, Rosati's fundamental theorem of matrices may be deduced readily from his observations on the pseudo axes of such a matrix Rosati's statement with regard to the indices of what he calls minimum invariant varieties is contained in propositions already established in the author's earlier publications —**R Marcolongo** The geometrico mechanical investigations of Leonardo da Vinci These investigations are classified into the following groups on lunes and on the quadrature of plane figures limited by circular arcs, on the transformations of solids into equivalent solids under given conditions, on the problem of incidence or Alhazen's problem, on the centres of gravity of plane and solid figures, on the construction of mathematical instruments Leonardo discovered and demonstrated the theorem of the meeting point of the axes of a tetrahedron but it does not appear that he showed this to be the barycentre of the tetrahedron For the centre of gravity of a semicircle he not only gave an approximate calculation, but he also used the method of decomposition into elementary sectors, thus reducing the problem to that of the graphic composition of a system of parallel forces With slight variations, his precision compasses are still sold, and he designed also a parabolic compass **A Amerio** New method for measuring the velocity of sound in liquids In this method, use is made of the very sensitive property of the ear which allows it to determine the direction of origin of a sound when this lies in the horizontal plane passing through the ears —**S Franchi** The importance of the San Remo and Imperia sheets of the 1 100,000 geological map of Italy for the solution of questions of Alpine and Apennine geology —**A Comessatti** The curves of Galois (1) —**T Boggio** Riemann's homograph for the hyper surfaces of a curved space —**S Cherubino** Decompositions in sums of squares of definite and semi definite polynomes —**E Bompiani** The elements of the second order of curves of a surface In previous notes the convenience of associating, with an element of the second order of a curve traced on a surface of ordinary space, two quadrics termed asymptotic osculatory quadrics of the element, was indicated Considerations analogous to those evolved in these notes point to the possibility of associating with such an element two new quadrics, of which the equations are now given —**N Moushkhelichvili** The problem of the torsion of isotropic elastic cylinders —**A Masotti** The dynamic actions in a system of rectilinear vortices —**G B Lacchini** The limits of visibility with refractors of small dimensions —**A Carrelli** Broadening of lines by resonance (2) Experimental results are given which, in conjunction with those of the author's previous communication on this subject, show that the widening of a spectral line in emission varies as the square root of the concentration of the vapour, and that the distribution of the intensities follows an exponential law These conclusions were derived by Holtzmark on the basis of the theory of absorption founded on the mutual action of similar resonators —**Angelina Cabras** Functional operations of mathematical physics represented as rational

functions of the symbol of derivation - **B Rossi** The Raman effect and negative absorption The Raman effect is usually regarded as an experimental proof of the induced emission or negative absorption postulated by Einstein in his deduction of Planck's formula Closer examination of this interpretation reveals difficulties Thus, if Einstein's induced emission resembles a Raman effect of the second species, it should possess a frequency double that absorbed or emitted spontaneously by the atom Exact analysis shows that the corpuscular theory of light renders it possible to unite the Raman effect and the phenomena of absorption and emission (spontaneous and induced) in a coherent scheme according to which the Raman effect of the second kind is considered as a super elastic impact of a light quantum with an excited atom and induced emission as a modification of the probability that an atom will emit a radiation of given frequency as a result of the presence of other quanta of the same frequency - **G Malquori** The system, $Fe(NO_3)_3 - HNO_3 - H_2O$ at 25° Study of this system gives results which exclude the existence of the acid salt $Fe_2O_3\ 4N_2O_5,\ 18H_2O$ and indicate the presence in solutions highly concentrated as regards nitric acid of the solid phase $Fe(NO_3)_3,\ 6H_2O$ —**D Bigiavi** and **S Stefanic** Action of diazotates on azoxyphenols When treated with bromophenyldiazonium hydroxide, *a* benzeneazoxyphenol yields directly the corresponding hydroxyazo compound, whereas its β isomeride gives a diazo ether, which is able to undergo coupling with β napthol and also rapid transformation into the isomeric hydroxyazo compound —**V Montoro** The supposed sesquioxide of molybdenum According to Guichard (1901), molybdenite is converted into the compound Mo_2S_3 when heated in a carbon crucible in the Moissan furnace for four minutes by an arc carrying 900 amperes at 50 volts X ray examination of a number of specimens of molybdenite partially desulphurised in this way shows however, that these consist of mixtures of the disulphide with solid solutions of carbon in molybdenum This result confirms Parravano and Malquori's conclusion drawn from an investigation of the equilibrium of the reduction of molybdenite by hydrogen, that no molybdenum sulphide exists which is less rich in sulphur than the disulphide —**L Passerini** Investigations on spinels The compound $MgCr_2O_4$, obtained by calcining a mixture of the nitrates of the two metals at about 800°, and $NiFe_2O_4$, similarly obtained from the corresponding hydroxides, crystallise in the cubic system with a lattice structure of the spinel type For $MgCr_2O_4$ the side of the unit cell is $a = 8\ 290 \pm 0\ 005$ A, the volume of the cell $v = 569\ 72 \times 10^{-24}$ c c, and the calculated density 4 49, for $NiFe_2O_4$ the corresponding magnitudes are $8\ 340 \pm 0\ 005$ A, 580 09 $\times 10^{-24}$ c c, and 5 268 respectively —**C Antoniani** and **G Fonio** Investigations on the interchange of the phosphoric acid of the soil with arsenic acid When soil which has been treated with sodium phosphate is afterwards treated with dilute arsenic acid solution, the phosphate anion is replaced to some extent by the arsenic anion —**G Mezzadroli** and **E Vareton** Action exerted by an oscillating metallic circuit on the germination of seeds Experiments with beans, wheat, barley, and beet show that the presence of an oscillating circuit with a single coil, 30 cm in diameter, capable of catching natural cosmic waves of wave length about 2 metres, exerts a favourable influence on the germinating power of seeds, the time of germination being reduced, in some cases, by one half —**M Cassinis** and **L Bracaloni** Hydremic curves —**B Aloisi** Hæmolytic poisons and alterations of the liver

Victoria Institute (at Central Buildings, Westminster), at 4 30 —Sir Ambrose Fleming Nature and the Supernatural (Presidential Annual Address).

Royal Society of Edinburgh, at 4 30 —Prof. W C M'Intosh On Abnormal Teeth in certain Mammals, especially in the Rabbit.—Dr I Sandeman Bands in Hydrogen related to the Fulcher System.—J A V Butler and W O Kermack The Action of Salts of Polynuclear Bases on Colloidal Suspensions and on the Electro-capillary Curve.—Sir Thomas Muir The Theory of Skew Determinants and Pfaffians from 1891 to 1919

Royal Institution of Great Britain at 5 —General Meeting

British Psychological Society (Education Section) (at London Day Training College) at 6 —Miss E M Terry Individual Difficult Children

TUESDAY June 4

Institution of Gas Engineers (at Institution of Civil Engineers) at 10 A M —Annual General Meeting (continued on June 5, 6 and 7).

Royal College of Physicians of London at 5 —Dr H H Dale Some Chemical Factors in the Control of the Circulation (Croonian Lectures) (I)

London Natural History Society (at Winchester House E C), at 6 30 —H J Burkill The Yorkshire Derwent

Illuminating Engineering Society (Annual General Meeting) (at Royal Society of Arts) at 7 —Dr J F Crowley Some Further Applications of Synchronously Intermittent Light for Revealing Moving Machinery

WEDNESDAY, June 5

Entomological Society of London, at 8 —Dr H Scott An Entomological Excursion into Basuto Land

THURSDAY June 6

Royal Society at 4 30 —Prof E A Milne The Structure and Opacity of a Stellar Atmosphere (Bakerian Lecture).

Institute of Pathology and Research (St. Mary s Hospital), at 5 —Prof W Bulloch The History of Bacteriology

Royal College of Physicians of London at 5 —Dr H H Dale Some Chemical Factors in the Control of the Circulation (Croonian Lectures) (II)

Chemical Society at 8 —F Challenger L Klein and T K Walker The Production of Kojic Acid from Pentoses by *Aspergillus Oryzæ* —Prof T M Lowry and G Jessop The Properties of the Chlorides of Sulphur Part II Molecular Extinction coefficients —M S. Lesslie and E E Turner The Isomerism of Derivatives of 2 phenylnaphthylene 1 8-diamino —Prof T M Lowry and F L Gilbert Studies of Valency Part XIII Further Experiments on the Molecular Structure and Configuration of the Quadrivalent Derivatives of Tellurium

FRIDAY June 7

Genetical Society (at Linnean Society) (Annual General Meeting), at 3 —Prof D E Lancefield The Genetics of *Drosophila obscura* —Dr C Stern Some Recent Work on *Drosophila*

Philological Society (at University College) at 5 30 —Dr C T Onions The Supplement.

Geologists Association (at University College) at 7 30 —Dr A K Wells Dr A. Brammall and others Discussion on The Value of Petrographic Character as a Criterion of Age

Royal Institution of Great Britain at 9 —C Leonard Woolley Excavations at Ur 1928–29

CONFERENCES

June 5 to 8

South Eastern Union of Scientific Societies (at Brighton).

Wednesday June 5 at 2 45 —W C Wallis Brighthelmstone of Early Times.—Sir Arthur Smith Woodward The Willett Collection of Chalk Fossils.

At 8 —Sir Arthur Keith Southern Englishmen of the Pre Roman and Roman Period (Presidential Address).

Thursday June 6 at 11 A M —A H Allcroft Archæological Address —A D Cotton The Importance of the Study of Systematic Botany

At 12 —J H Pull The Blackpatch Excavations.—G Morgan The Etiology of Sphæroblasts or Wood nodules

Friday June 7 at 11 A.M —H Dewey The Denudation of the Weald —Dr G P Bidder Death (Address).

At 12 —E A Martin The Brighton Rubble Drift, and Cliff Formation —A. Griffith Some Sussex Birds and Insects

At 8 —Reginald A Smith Early British Art (Public Lecture).

Saturday June 8, at 10 30 A.M —Prof H J Fleure Regional Survey Address.

At 11 30 A.M —D Edwards Town and Regional Planning.

June 6 to 15

International High Tension Conference (at Paris)

June 11 to 22.

Institution of Electrical Engineers.—Summer Meeting in France

PUBLIC LECTURES.

FRIDAY May 31

Chelsea Physic Garden, at 5.—H. V Taylor Supplies from the Vegetable Kingdom and the Public Health (Chadwick Lecture).

MONDAY, June 3.

King s College, at 5 30.—Prof P Karrer Organic Chemistry (Succeeding Lectures on June 5 and 6.)

FRIDAY, June 7

King s College, at 5.30 —Prof. H. Wildon Carr The Philosophy of Leibniz. (Succeeding Lectures on June 10, 12, 14, 17, and 19)

SATURDAY, JUNE 8, 1929

School Science

THOSE in touch with educational circles have been aware for some time past of a growing dissatisfaction with the scope and treatment of school science The Report of the Committee of the British Association upon Science in School Certificate Examinations[1] thus comes at an opportune moment, and will be welcomed by all who realize the difficulties of the present position It is not an easy matter to probe to the root of the widespread feeling that all is not well with science in the schools, but at bottom there seems to be a conflict between utilitarian and æsthetic ideals Many teachers recognizing that the majority of their pupils will have to work hard for a living, feel that they must be given instruction of immediate practical value others emphasize the importance of training young people to appreciate to the full the serene joys of the intellectual life These two aims are not necessarily incompatible and their reconciliation might be effected with reasonable ease, were not the situation rendered almost hopelessly rigid by the incubus of examinations

There are in England and Wales eight examining bodies which conduct First and Higher School Certificate examinations taken by boys and girls at the ages of 16 and 18, or thereabout, respectively Through the activity of the Secondary School Examinations Council, these several examinations have been closely equated, and there is now little variation among them in syllabus and standard This uniformity is in many ways a good thing, but the disastrous result of a comprehensive yet stereotyped examination system has been to stifle originality in teaching, and to raise the list of examination successes into a fearful idol, to be at once worshipped and dreaded The effect upon science has been particularly devastating, owing to the special circumstances Science is a comparative new comer to the school curriculum, and a mere half century's experience has proved insufficient to enable teachers to work out the most suitable and efficient means of teaching it Yet, while still in this immature state, school science is becoming petrified by examination requirements, and the evil habit of 'cramming' is likely to establish itself firmly unless immediate steps are taken to prevent the catastrophe

The Committee not only points out the danger, but makes valuable suggestions for avoiding it It favours a scheme whereby schools may arrange

[1] British Association Reprints No 23 Report on Science in School Certificate Examinations Pp 443 532 (London British Association, 1928) 1s

their own plan of work, and examine their own pupils in association with independent boards of assessors Such a scheme is already in operation in certain technical schools, where a national certificate is awarded under the joint supervision of the Board of Education and the Institution of Mechanical Engineers, and a similar scheme has been adopted by the University of London for the examination of the twenty-two training colleges allotted to it If a system of this kind were generally adopted, with adequate safeguards, teachers would have far more freedom to elaborate methods and courses of work suited to particular needs, and school science would have the opportunity of advancing on the lines of true culture

Present conditions are responsible for a further regrettable tendency in elementary science teaching, namely, a concentration upon formal chemistry, physics, and, to a less extent—principally in girls' schools—botany Although something may be said for such a study at the stage of the Higher Certificate, it is very doubtful whether boys and girls of 14 to 16 really derive any great permanent benefit from a diluted form of academic science The 'theory' of chemistry and physics, and even of botany, is in fact not appropriate to the general education of the middle school A few bright pupils may benefit, but teachers and examiners alike realize that most of the candidates are drowned in a boundless sea of definitions, laws, and hypotheses, of a depth to them unfathomable

Still another conspicuous defect in school science is the infrequency with which biology forms a part of the regular routine Whatever we may regard as the primary aims of teaching science to boys and girls, we must certainly include among them that of imparting an elementary knowledge of the phenomena of life It is therefore extremely disconcerting to find that many, if not most, of our children may pass through the schools without receiving any instruction whatever in biology There are, of course, explanations of this remarkable state of affairs In the first place, the majority of science teachers have specialized in chemistry or physics, or both, at the universities, and are thus content, in general, to teach those subjects only, at any rate, no active demand for biological work is likely to proceed from teachers of the exact sciences unless a stimulus is applied from without Secondly, it has been—and is—maintained that biology has too recently emerged from the purely descriptive stage to lend itself to the inculcation of scientific method, whereas chemistry and physics may be very easily adapted to this end Lastly, we are reminded that biology is based largely upon chemistry and physics, and that logic consequently demands a study of at least the elements of the two latter sciences as a necessary preliminary to biological work It is clearly an urgent matter for the biologists to show how these difficulties can be removed

Such are the principal facts relating to the present condition of science in schools It remains to consider them in relation to the strife between æsthetic and utilitarian ideals which we believe to be the real cause of the prevailing controversy Since modern civilization depends for its very existence upon the application of scientific knowledge, no one will deny the importance of teaching young citizens a modicum of scientific facts Moreover, technical occupations absorb increasingly large numbers of workers, and must continue to do so as long as civilization persists it may thus be of direct practical and financial value to a boy or girl to get elementary technical instruction at as early an age as possible These two points are, in brief, the arguments of the utilitarian school, and they undoubtedly have much weight If they carry the day, they will tend to preserve the existing scheme of formal chemistry and physics, and to exclude biology until biological callings have increased to such an extent as to offer wide and immediate prospects

Even those teachers, however, who most strongly urge the utilitarian aims agree that science, as part of a general education, should do more than impart useful information There is, in fact, an almost universal feeling that the æsthetic side of science is ultimately the most vital, but opinions differ as to the degree and manner in which this aspect is to be emphasized Stern disciplinarians, who themselves experience an austerity of pleasure in fundamental scientific philosophy, make superhuman efforts to transmit some shadow of this pleasure to restive school certificate sets, the rare occasions on which their labour gets the full appreciation it deserves are a sufficient recompense for many failures It is a commonplace that such teachers are usually regarded with no little reverence by their pupils in after years, but the reverence is rather for the man than for his teaching

There are, again, those teachers who strive 'to make science easy', and in doing so run dangerously near the borderline of insipidity scientific facts, as such, are of no greater educational worth than the date of Waterloo or the names of Henry VIII's wives To know how an electric bell works is not necessarily to be educated It is seductively

attractive to make one's science course a series of superficial explanations of devices and phenomena, and to imagine that one is revealing the beauties of science

This has been the chief criticism levelled at 'everyday science', 'science for all', or 'general science', but it is a criticism easily disposed of, since it rests upon a misunderstanding The advocates of general science' have been envisaged as those who would replace the very real (if limited) benefits of formal science by the illusory returns of a shallow smattering Nothing could be farther from the truth 'General science', as properly interpreted by the Committee, is an attempt to make children see science steadily and to see it whole, to enable them to assimilate scientific principles and scientific method by a consideration of phenomena from the point of view of every relevant branch of science and to increase their capacity for intellectual pleasure by opening to them the inexhaustible treasures which science discovers in the world of everyday life The 'general scientists', in fact, are thorough going supporters of the æsthetic aim, though sometimes they disguise their real sentiments by pointing out the immediate practical value which the course they suggest may possess It is true that a scheme of 'general science' may include lessons on severely practical topics, but the whole spirit of the course is to relegate the purely utilitarian aim to a definitely lower place

Unfortunately, 'general science' has to fear two extremely serious perils The first is that it can so easily be transformed into a grotesque caricature, becoming, indeed, the smattering which it strives to avoid The second is that it is incomparably more difficult to teach than the formal chemistry or physics or botany at present in vogue If it is to achieve its purpose, the first essential is to dispel the notion that 'general science' is a soft option, to be welcomed for the sake of weaker candidates, but otherwise to be disparaged This difficulty in teaching will, we fear, be very troublesome to overcome, but examining bodies may do something by encouraging schools to take general science, and by allowing a wide choice of questions in the papers

Specialization at the later stage, that of the Higher Certificate, is probably inevitable Yet we admit surprise at the qualified blessing which the Committee gives to the Higher Certificate Examination, for we cannot bring ourselves to believe that it is good for boys and girls of 16 18 to devote three quarters of their school time to the study of only two or three special subjects We should like to see a broader basis for the examination, with a less intensive treatment Similar remarks apply to the university scholarship examinations, which demand what is practically degree knowledge from the candidates, and do more to sophisticate adolescent education than any other single factor E J HOLMYARD

The Place of Science in our View of History

The History of British Civilization By Dr Esmè Wingfield Stratford Vol 1 Pp xv + 574 Vol 2 Pp viii + 575 1332 (London George Routledge and Sons, Ltd , New York Harcourt, Brace and Co , Inc , 1928) 42s net

ON several occasions the pages of NATURE have afforded evidence of the growing importance taken by science in the writing and teaching of history It is in fact at the root of the difficulty which was dealt with recently in one of the leading articles How to secure that our political leaders and one might well add leaders of all other kinds—should approach their business in a scientific spirit? There are, of course, many ways by which the change will come, and is coming, but it may be doubted whether any way will affect a larger number of persons than that of infusing the ordinary teaching and view of history with some notion of the part that science has played in the process For we all learn some history Not only at school but also in after life so far as we do any serious reading at all, it is of a historical kind floods of memoirs and biographies are being constantly poured out by the press

Here is the main source of intellectual influence which is playing upon the more thoughtful sections of the public, it is here that science must make its way It is therefore an interesting study—more interesting every time—to measure the space which science occupies in works of general scope, especially when they purport to talk of civilisation as a whole, and, most of all, of modern civilisation Such a book has just appeared in Mr Wingfield Stratford's "History of Civilization", which has had a remarkably good press and promises, if he can induce his publishers to produce a cheaper edition to have a powerful influence in forming British opinion about its own past It has all the elements of sound popularity for an English public, a vigorous full blooded style, a freedom of personal judgment, an absence of pedantry or the apparatus of learning, a readiness to admit national crimes and defects, and a glorious ending on the right side, with the British Commonwealth of

Nations standing for the cause of humanity, and encompassed by the greater League of all nations

It is a capital and most interesting book, well deserving its success But we are looking at it here from the special point of view of science, and in that respect it marks an advance, and yet, even perhaps more strongly, shows where the next advance must follow Some six or eight short sections out of 1300 pages are given to an account of the men of science themselves, who, except Roger Bacon, are justly appreciated, and the right place of science, in first accelerating and then controlling the Industrial Revolution, is well indicated This is something to be thankful for, much more and in a better spirit than in the books of our youth, where we were lucky if we found Newton mentioned at all, even as Master of the Mint

It is still very inadequate, however, and we should like to make the inadequacy patent to Mr Wingfield Stratford and any other open minded writer of books on history by two considerations, one of a particular and the other of a general kind To take the particular example first He gives us pages of a highly amusing and instructive kind on the progress of Mr Bernard Shaw to fame, his shameless self advertisement, his gibes and clever plays He does not do this on account of his socialism, for it does not appear that the author is a socialist He does it because of its personal interest and because in the end Mr Bernard Shaw did attain the notoriety at which he aimed No doubt also it is one of the reasons why we find the book so interesting Now just at this time one of the greatest pieces of scientific construction in the history of mankind was going on, the development of the new astronomy which has given us the amazing view of the universe which fills the mind of all who have approached it with a fresh unquenchable curiosity and the profoundest admiration for its creators It happens that the two most prominent names in this army are Englishmen, Jeans and Eddington, and their work must have a lasting influence on the way we both think and act Yet in the book before us there is not a word about it

That is one of many cases which might be quoted from a book in which the general spirit of the author is quite favourable to science If these things are done in the green tree—— ? The general criticism connected with this is more intangible and may not carry conviction so readily to every mind This book, and most surveys of modern history, end on a note of poignant resignation, not of despair but of horror and uneasiness, of hope against hope We believe this tone to be largely due to the divorce of the literary mind from science The literary mind being personal, sensitive, and often ephemeral, is naturally obsessed by the suffering and tragic conflicts of the War It is right that we should have these things brought prominently before us A heartless science would be worse than untutored savagery But it is essential that those who aim at putting forward a general view of human progress, which is what a history of civilisation must mean, should have regard to the dominant and lasting factors

On this view, what is the most striking fact about the world towards the end of the nineteenth century and the beginning of the twentieth, above all in the throes of the War ? Surely its stability in spite of conflict, its recovery in spite of stupendous loss Were a stranger from Mars to visit this planet without a knowledge of what we have gone through in the last fifteen years, he would not report a scene of desolation or decadent idleness or internecine strife, but a hive of industry, a network of intercourse, a fertility of invention, and a range of thought which, on inquiry, would appear far to exceed anything in the human record The black spots, such as parts of China and Russia, would also on inquiry be found to be precisely those places where the organisation, provoked and carried out by scientific thinking, were the least developed

It is curious that this, which will certainly be the most commonplace observation about twentieth century civilisation by the historians of the future, is at present so rarely made It is due no doubt to the political and still more the literary preoccupation of the bulk of contemporary historians The League of Nations is gradually but with difficulty fighting its way into the pages of history and the everyday thinking of mankind But the foundations of the League, which lie much more in the cultural, economic, and scientific region than in the declarations of statesmen, have still to be dragged into the daylight The activities of commerce and transport, the agreements as to disease, hygiene, slavery, and the like, above all the supreme constructions of the mind, such as the new cosmogony instanced above, are all international and—in the broad sense—scientific, and, until the historians come to their work with a mind awake and to some extent instructed on this side, justice will not be done to the most vital aspects of the modern world Above all books, a 'history of civilisation' should give due place to these things, for what is modern civilisation if we leave out science ?

F S MARVIN

Statistical Mechanics

Statistical Mechanics the Theory of the Properties of Matter in Equilibrium Based on an Essay awarded the Adams Prize in the University of Cambridge, 1923–24 By R H Fowler Pp viii + 570 (Cambridge At the University Press, 1929) 35s net

THE motion of a given conservative dynamical system is a problem which can be reduced to the consideration of the properties of the functions defined by its Hamiltonian equations of motion These equations are themselves deduced by allowing infinitesimal departures of the system from its actual course In an endeavour to base the laws of thermodynamics on mechanical grounds, Maxwell, Boltzmann, and Clausius were led to consider assemblies of similar systems, each possessing its own configuration and velocities Even were it possible to describe minutely the configuration at a given time of each member of an assembly consisting of a large number of such systems, it is doubtful whether our senses would be acute enough to appreciate the implications of such a description

There is, however, another direction in which such inquiries may be pursued, namely, in an investigation of the law of distribution at a given instant of all the systems among the various possible configurations and velocities The number of systems which fall within given infinitesimal limits of configuration and velocity will in general depend not only on the generalised co ordinates and momenta, but also on the time Where this dependence does not involve the time, we have statistical equilibrium The problem which is now of paramount interest is the search for the normal or time average properties of such an assembly The only method of finding these averages which is amenable to exact treatment appears to be an identification of them with averages taken over the accessible phase space of many dimensions by means of which the configuration and velocities of the assembly may be described

The average value of statistical mechanics may be regarded, as indeed they were by Boltzmann, Gibbs, and Planck, as values of maximum frequency of occurrence Mr R H Fowler prefers to obtain them by assigning 'weights' rather than probabilities, a method which leads to a more rigorous mathematical treatment As the immediate object is to treat statistical problems from the point of view of the classical quantum theory, this theory is regarded as fundamental, and classical systems are introduced as the limit, for large quantum numbers, of quantised systems This unusual procedure is justified by the remark that the laws of quantised systems cannot be obtained from those of classical systems The rules for assigning weights and the definition of normal properties as averages over the accessible phase space are of course the crux of the whole matter, they may even be looked upon as a postulation of the solution No attempt is made to disguise this logical hiatus, and it would seem that some such gap must always arise in the application of a mathematical theory to the physical world It is, indeed, an advantage that the crucial assumptions should not appear in a more subtle way

The rules for weighting are as follows

(i) To each element of phase space of a classical system is attached a weight proportional to its extension, namely,

$$(dp_1 \quad dq_s)/h^s$$

(ii) To each mechanically possible stationary state of a non degenerate quantised system is attached a weight unity

(iii) To each state of a degenerate system is attached a weight equal to the number of different stationary states of some non degenerate system which coalesce under adiabatic transformation in the limit to form the given state of the degenerate system

No general proof has been given that the weight of a degenerate system so defined is unique, nor is a general rule available for counting the non degenerate states This can scarcely be called a defect of the method, but is rather a limitation on our present state of knowledge These weights are adiabatic invariants in the sense of Boltzmann A simple example of an adiabatic invariant was given by Einstein in 1911, namely, the ratio of the mean kinetic energy of a simple pendulum to its period when the string of the pendulum is shortened infinitely slowly

Having arranged a system of weighting, the next step is to calculate average values This is done by constructing partition functions, which in the simplest cases are power series, the coefficients of which are the weights The average values are expressed as contour integrals involving these partition functions, and these integrals are then evalued by the method of steepest descents This is an extremely elegant and powerful mode of attack, and it is significant that the parameter ϑ which presents itself in the application of the

method can be interpreted as a function of the absolute temperature T, the actual relation being $\vartheta = e^{1/k}$, where k is Boltzmann's constant Gibbs considered assemblies of classical systems canonically distributed in phase, that is, those in which the index of probability is a linear function of the energy and containing a 'modulus of distribution' analogous to the temperature The partition functions are the generalisation for quantised systems of the phase integrals of Gibbs

After applying the above considerations to obtaining the statistical distribution laws of perfect gases, crystals, radiation, etc, the relation of thermodynamics to the equilibrium theory of statistical mechanics is established by showing that thermodynamical laws are true for the assemblies considered An extremely interesting and searching criticism is given of the method originated by Boltzmann and extended by Planck of introducing entropy by relating it to probability, a method which is claimed to be "obscure or misleading and certainly unnecessary" The author's argument is cogent and deserves to be read with care, but it is certainly surprising that the method has passed so long unchallenged

From this point the theory is developed in numerous aspects Nernst's Heat Theorem imperfect gases, thermionics stellar interiors, to mention a few of the topics treated Dr Lennard Jones has contributed an interesting numerical survey of intermolecular forces The author's object has been throughout to develop a consistent theory completely, and this object has certainly been achieved The bearing of the new mechanics has been summarised in the last chapter, the important result being found that the accessible phase space of the classical theory must be cut down to states appertaining to a selected group of wave functions

The leading comprehensive treatise in English on the statistical mechanics of an assembly of classical conservative dynamical systems is that of J W Gibbs, published in 1902 Since that date mechanical ideas have travelled far, and in the light of the new mechanics we have now to talk of a classical quantum theory Mr Fowler has written a worthy successor to the work of Gibbs, and it is to be hoped that, when the time is ripe, it will be followed by a treatise based entirely on the new mechanics Until that time arrives the present volume must remain the most authoritative source of information on the subject as a whole

L M MILNE THOMSON

Statistics in Biological Research

Statistical Methods for Research Workers By Dr R A Fisher (Biological Monographs and Manuals No 5) Second edition, revised and enlarged Pp xii + 269 (Edinburgh and London Oliver and Boyd, 1928) 15s net

WITH the increasing application of statistical methods to new fields of work, the problem of the handling of small samples has become more and more important It is true that the larger the sample the more trustworthy are the inferences which can be drawn from it, but there are certain problems, whether biological or industrial, in which the time and cost involved in obtaining even a moderately large sample would be quite prohibitive This need for a development of small sample theory has emphasised the importance of placing the methods of inference on a clearly defined and logical basis For loose thinking and careless interpretation are both easier and more dangerous when dealing with small than with large samples The aim of the statistician must be to bring the simplifying assumptions of theoretical analysis into correspondence with the varied and complex situations of practical work

Dr Fisher sets out in the introduction to this book, of which a second edition has been published recently, what may be termed his statistical philosophy It may not perhaps be easy to follow at a first reading—perhaps not before his mathematical papers published elsewhere have been read and if necessary interpreted in more familiar terms—but a grasp of the ideas involved is essential to a clear understanding of his methods These are perhaps, after all, more like those criticised than he will allow, but the line of approach is somewhat different His aim has been to develop on systematic lines a series of tests appropriate for use in a great variety of problems This has involved a very considerable extension of theory, based in several cases upon a most elegant use of the geometry of multiple space These proofs are not, of course, given in the present book, which is primarily intended for biological research workers, but the practical applications of the methods to a variety of problems are given with numerical illustrations, and the necessary probability tables

To discuss how far the author has achieved his object of putting clearly before the research worker the means of applying statistical tests, would require perhaps a reviewer who is a non mathematical biologist There is one criticism, however, which must be made from the statistical point of

view A large number of the tests developed are based upon the assumption that the population sampled is of 'normal' form That this is the case may be gathered from a very careful reading of the text, but the point is not sufficiently emphasised It does not appear reasonable to lay stress on the 'exactness' of tests, when no means whatever are given of appreciating how rapidly they become in exact as the population sampled diverges from normality That the tests, for example, connected with the analysis of variance are far more depend ent on normality than those involving 'Student's' z (or t) distribution is almost certain, but no clear indication of the need for caution in their applica tion is given to the worker It would seem wiser in the long run, even in a text book, to admit the incompleteness of theory in this direction, rather than risk giving the reader the impression that the solution of all his problems has been achieved The author's contributions to the development of 'normal' theory will stand by themselves, both for their direct practical value and as an important preliminary to the wider extension of theory, with out any suggestion of undue completeness

A last chapter on the principles of statistical estimation has been added to this edition It provides a good illustration of the application of the ideas contained in the introduction and else where, although perhaps it may prove stiff reading for the biologist

Our Bookshelf

The Works of Aristotle Translated into English under the Editorship of Dr W D Ross Vol 1 *Categoriæ and De Interpretatione*, by E M Edghill, *Analytica Priora*, by A J Jenkinson, *Analytica Posteriora*, by G R G Mure, *Topica and De Sophisticis Elenchis*, by W A Pickard Cambridge Pp iv + 652 (Oxford Clarendon Press, London Oxford University Press, 1928) 15*s* net

This substantial volume is the first of a series to be added to the well known Oxford translations, which is to include the whole of the extant works of Aristotle The six treatises of which this book consists constitute Aristotle's immense contribution to what became known later as the science of logic The translation faithfully reflects the nature of that contribution

One might gather from the statements made in many a compendium of the history of philosophy that Aristotle worked out a systematic treatment of logical science This is not the case All the same, he was the real founder of logic as a distinctive discipline, and it was he who made the wonderful discovery of the nature of syllogistic inference His work is set forth in this translation in a manner which will not only satisfy the scholar, but will also make it accessible to educated readers who cannot pretend to be scholars The four con tributors to the volume have worked under the general editorship of Dr W D Ross, whose guidance and inspiration each of them in turn gratefully acknowledges

The Statesman's Year Book Statistical and His torical Annual of the States of the World for the Year 1929 Edited by Dr M Epstein Sixty sixth Annual Publication Revised after Official Returns Pp xxxii + 1448 (London Macmillan and Co, Ltd, 1929) 20*s* net

This valuable year book has again undergone a thorough revision and incorporates the latest official statistics up to the time of going to press The lists of books of reference have also been revised Notable events have occurred in many States during the year, such as the establishment of a central government with new capital in China, the transformation of Albania from a republic to a monarchy, and the restoration of the temporal sovereignty of the Pope These and other events are duly noted, but the list of separate States now remains the same, and there have been few terri torial readjustments during the year The intro ductory tables include several of world production of selected commodities In one respect the value of the book could be enhanced that is by the inclusion year by year of more tables of this kind There is the usual section on the League of Nations The coloured maps show the City of the Vatican (on a large scale) and the Peru Colombia boundary adjustment The size of the book has been slightly reduced, mainly by the condensation of the index, which does not, however, impair its value

The Annual Register a Review of Public Events at Home and Abroad for the Year 1928 Edited by Dr M Epstein Pp xiv + 316 + 166 (London, New York and Toronto Longmans, Green and Co, Ltd, 1929) 30*s* net

This well known work of reference has now reached its hundred and seventieth volume, a length of life which alone expresses its value It continues on the lines of previous issues The first part, consisting of about 300 pages, is a survey of the history of the world during the year As usual, this survey is conspicuous for its completeness and lucidity Nothing of importance seems to be omitted In the second part of the book there are a chronicle of events which do not fall within the scope of the historical survey, and obituary of some hundred or more eminent men of all nations The retrospect of achievements during the year devotes nine pages to a record of science, which is little enough compared with literature and finance, but the scientific chapter is nevertheless an excellent survey of the year's progress The public documents given in full this year are the Kellogg Pact, the Convention of the Pan American Union, the Agree ment with Transjordania, and the Anglo Chinese Treaty

New Evidence of the Action of Sunlight on Aurora Rays

ON Mar 15 last I received information from the State Telegraphic Department that earth currents were disturbing the telegraphic service Believing that we should have an aurora in the evening, I warned my four photographic stations, Oslo, Kongsberg, Tömte, and Oscarsborg, to be ready for action immediately after sunset Using the excellent type of direct vision spectroscope described by Lord Rayleigh,[1] I was able to localise an aurora arc in the northern sky during the twilight, long before it was possible to distinguish it visually

The photographic work began as soon as the sky had become dark enough, and a long series of photograms were taken simultaneously from two, three, or four stations during the whole night, among these are 14 quite successful ones from two stations, 38 from three stations, and 12 from four stations I led the work from my station Oslo, but was obliged to go home about midnight G M T Before going away I asked my excellent collaborators, Wesöe and Tveter, to continue until the dawn and keep a good look out for sunlit aurora rays, which might probably appear in the late hours of the night Their perseverance was richly rewarded At 2 h 40 m G M T, three hours before sunrise, there suddenly appeared in the north-east long bluish pale aurora rays which developed

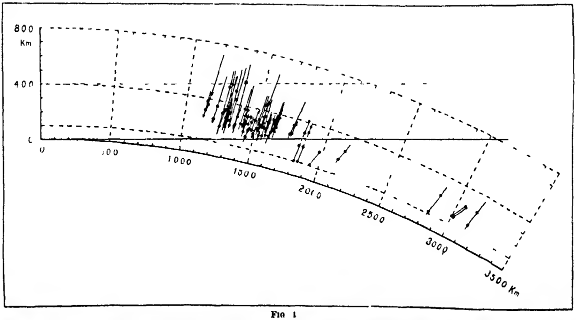

FIG 1

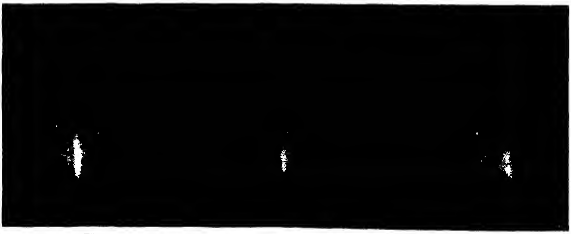

TÖMTE OSLO KONGSBERG

FIG 2 —Photographs of aurora taken simultaneously at the places indicated under them

[1] On Visual Observations of the Aurora Line in the Spectrum of the Sky at Night *Gerlands Beiträge zur Geophysik*, vol 19, pp 292 297

westwards and continued until 3 h 30 m G M T Meanwhile, at the station Oscarsborg, where Hafnor was working, the sky had become overcast, but the other three stations were now taking simultaneous photographs as fast as possible one after another, and a large number of successful photograms were secured At Oslo the photographs were taken by Tveter, at Kongsberg by Busengdal junior, and at Tomte by the Antarctic explorer Carsten Borch grevink

The measurement and calculation of those sunlit aurora rays have been made by my assistant Wesöe and myself and their position relatively to the earth's shadow calculated Also the other not sunlit aurora rays of the same night have been treated in the same manner

On the accompanying diagram (Fig 1) is seen the position of all the rays of the night of Mar 15–16 compared with the position of the earth's shadow The figure represents a vertical section of the earth, and the tangent to the earth's surface is the boundary between the sunlit and dark atmosphere For each point of an aurora ray the position in the vertical plane through the centre of the earth and the sun is marked by a small circle On each aurora ray two points are calculated and combined with a straight line representing the ray This line is continued beyond the points as far as the photographs indicate If the ray passes out of the photographic field it is marked by an arrow, and if the foot or summit can be seen on the photograph no arrow is given

FIG 3 —The rays as seen from Kongsberg Oslo and Tömte are marked by the letters K C and T Corresponding points have the same number

The high rays were all lying in sunshine, and their lowest points, which have been measured with great care, are situated near the boundary between sunlit and dark atmosphere Some of the rays have their summits nearly 700 kilometres above the earth, and all lie far to the north, some even in the zenith of Tromsö and northern Finland The measurements are particularly trustworthy on account of the long base lines, 46 68 km from Oslo to Tömte, 65 70 km from Oslo to Kongsberg, and 105 14 km from Kongsberg to Tömte The results have further been controlled by calculating the height in choosing either Oslo—Tömte, Oslo—Kongsberg, or Kongsberg—Tömte as base lines

In contrast to these high rays, lower rays are seen to the right on the same diagram, they lie in the dark part of the atmosphere Thus some of the same general features are seen here as on the diagram published in my communication to NATURE of Jan 19, 1929 A new and extremely interesting phenomenon was, however, observed with certainty on that night for the first time Some of the rays consisted of two luminous parts, one situated in sunlight and another in darkness and connected by an invisible part, stretching from the boundary of the sunlight and downwards These rays are indicated on Fig 1, the invisible part being dotted On Fig 2 are seen the photographs of the rays at 3 h 16 m 29s G M T

The constellation Auriga with the star Capella are clearly seen on the photographs A sketch of the situations of the principal ray is seen on Fig 3 On the right border we have chosen the corresponding points 1, 2, 3, 4, 5, 6, and with the different base lines the following heights were found in km

Base line	Point 1	Point 2	Point 3	Point 4	Point 5	Point 6
Oslo Tömte		161	202	314	363	
Oslo Kongsberg		151	211	323	368	
Kongsberg Tömte	100	157	214	316	361	409

The lowest point of the upper part was found to be at about 296 km and the highest point of the lower part to be at about 223 km above the earth's surface, calculating the height of the boundary between sunlit and dark atmosphere at the situation of the ray, we found it to be 275 km

Thus the bundle of corpuscular rays causing the aurora ray at first illuminates the upper sunlit atmosphere, then the illumination ceases at the beginning of the dark atmosphere but begins again lower down, when the density of the air is great enough to excite luminosity The action of sunlight may be a direct one, as mentioned in my former note, or an indirect one in forming a tail which becomes luminous where it is penetrated by the bundle of corpuscular rays

CARL STÖRMER

Oslo

A Property of Superconducting Metals

IN a recent article by Kapitza (*Proc Roy Soc* A, **123**, 342, 1929) it is suggested that (1) superconductivity is a general phenomenon, which can exist in all metals, but (2) is "masked by an additional resistance which does not disappear in most metals at low temperatures" This additional resistance is supposed to be due to "structural and chemical imperfections of the metal" Regarding (1), it appears that the superconductors have a peculiar hitherto unnoticed property, which will be presented in more detail below Because of this, I am inclined to believe that (1) is incorrect (to all practical purposes) and that one could with equal right say that ferromagnetism is capable of existing in all metals, but is masked by other effects in some As to (2), it would seem that, since the conductivity in the superconducting state is of an entirely different order of magnitude from that of the conductivity of any normal metal, the additional resistance disappears owing to the short circuiting, by the pure superconductor, of the impurity or structural imperfection In the system non superconductor + impurity, the two resistances are not of such greatly different orders of magnitude, and so the impurity may have a quite marked effect on the resistance

If one plots relative resistance against temperature, for the various metals (excluding bismuth), with the aid of the tables given by Onnes and Tuyn (*Comm*, Leyden, Supp No 58), then the curve is as follows (1) At low T, for non superconductors, approximately horizontal, with a finite intercept on the resistance axis, (2) at higher T, convex toward the temperature axis, and (3) at still higher T, linear in T over a large range of temperature In an analogous fashion to Kapitza's one can extrapolate the two linear parts (1) and (3) to intersection, and obtain a 'critical temperature' When one plots this critical temperature against atomic number, the curve resembles somewhat that of the plot of the Debye characteristic temperature Θ against atomic number, although the connexion, if any, subsisting between these two temperatures is by no means obvious The striking fact that is observed is that in the case of superconductors, including the newly discovered ones, tantalum and thorium, the critical temperature lies quite low, and probably lower than in the case of non superconductors That is, the temperature coefficient of

relative resistance for part (3) of the curve is more nearly $\frac{1}{3}$ for the superconductors than for the other metals. For the same part of the curve, at any given temperature, that metal is most likely to become a superconductor which has the greatest relative resistance. One cannot say that every superconductor has a low characteristic temperature, that of tantalum being at 243° K (F. Simon, *Zeits f. Phys. Chem.*, **129**, 334; 1927). No superconductor as yet discovered has, however, a high critical temperature, and this fact seems to be more than a chance coincidence.

A superconductivity model which gives a qualitative picture of most of the facts is easily set up. One may think of a crystal as composed of two systems interacting with each other, namely, (1) the lattice with its characteristic vibrations and (2) the electron system, considering the lattice ions at rest. In case (2), which includes electronic interaction, one may theoretically solve a Schrödinger equation and obtain eigenvalues and eigenfunctions. The system (1) may then be considered as a perturbation acting on (2). One can assume that in the superconducting state the lattice has not sufficient energy to impart it in the form of kinetic energy to the electrons, but that the latter may only change their magnetic energy. Probably, also there is no net exchange of momentum between electrons and lattice. There subsist then, no inelastic collisions and no elastic collisions with loss of momentum, so that no resistance can enter.

As to the influence of the magnetic field and its parallelism with that of the temperature, one can be guided by the Heisenberg picture of ferromagnetism. At $T=0$, in a vanishingly weak external magnetic field, the elementary magnets (electron spins) all point in the same direction. If energy is imparted to the system, either because of an external field being applied or the temperature being increased, then some spins will now be 'antiparallel'. It is assumed that the first excited kinetic energy level lies quite high for the superconductors, so that the magnetic energy cannot be converted into kinetic energy. This marks the essential difference between superconductivity and ferromagnetism, as in the latter case the kinetic energy levels lie so close together (probably) that magnetic energy may be converted readily into kinetic energy and the system will come to equilibrium when as many spins as possible are parallel (consistent with the temperature agitation), while in the former case such a balancing between spins and temperature agitation is not possible.

This picture is advanced only tentatively, to account for the sharpness of the transition temperature and the parallel effects of magnetic field and temperature. Whether it is right or not will only be known when it becomes possible to correlate, at least qualitatively, the value of the transition temperature with other properties of the metal, and to explain the connexion of superconductivity with the character of the resistance curve. JAMES H. BARTLETT, jun.

Zurich, April 27.

MR. BARTLETT brings up in his letter a very interesting view to explain the disappearance of the residual resistance at the threshold temperature in supraconductors. As this residual resistance is produced by impurities or structural imperfections, it is suggested that it can be short circuited by the perfect (healthy) paths of the conducting metal, which suddenly acquire an abnormally high conductivity of quite a different order from that observed in ordinary metals.

This picture, however attractive it is at first glance, presents some difficulty on comparison with experimental data. If we take, for example, the measurement by Meissner of the resistance (*Phys. Zeit.*, p. 725; 1926) of very good crystals of gold, cadmium, and zinc, in which the residual resistance is many times smaller than in ordinary wires, this makes it possible to estimate the value of the ideal resistance at a low temperature more accurately, and it appears that at 4.2° K the ideal resistance cannot be of a greater order than 10^{-6} of that observed at 273° K, and if we extrapolate the ideal resistance to 1.3° K, we find it to be less than 10^{-7} or 10^{-8}. Only the upper limit can be fixed from present experiments, and the actual ideal resistance may be any number of times smaller. This order for the upper limit of resistance corresponds to that fixed by present measurements for all supraconductors (except lead, where it was proved to be less than 10^{-12}). Thus there is no experimental evidence "that the supraconductive resistance is of any entirely different order" from the ideal resistance of a metal at a correspondingly low temperature.

According to Mr. Bartlett's view, this low ideal resistance of the healthy spot of the crystal must short circuit the bad spots which contribute the additional resistance even for non-supraconductors, and this does not agree with experimental evidence; for most of the metals the additional resistance remains practically constant in the range of the lowest temperature. On the other hand, McLellan, Niven, and Wilhelm (*Phil. Mag.*, p. 678; 1928) find that although 2 per cent of cadmium added to lead increases very much the residual resistance, the lead still remains a supraconductor. In this case it seems to me there is very little room left for the healthy undisturbed crystal lattice, as in a line of atoms, on an average, a cadmium atom will be separated by only 3 or 4 atoms of lead.

The sketch of the theory of Mr. Bartlett is very interesting, and it will be most important to see it worked out and tested by experiment. It seems to me that at present the greatest difficulty which meets any theory of supraconductivity is to account, not for the high value of the conductivity, but for the suddenness of the phenomenon. This is especially difficult, since the experiments definitely indicate that no structural or thermal phenomenon occurs at the threshold temperature, and I fail to see how Mr. Bartlett accounts in his theory for the suddenness of the appearance of supraconductivity. In any event it is evident that, according to his views, the mechanism of supraconductivity must take place in the healthy paths of the metal, and we must expect that the threshold temperature will be independent of the kind of impurity and a constant for any given supraconductor. This does not seem to be strictly the case; for example, in indium in different specimens the threshold temperature was found to be different (Tuyn and Kamerlingh Onnes, *Com.*, Leyden, No. 167*a*, p. 6).

On my view, which was supported by the evidence obtained in experiments on change of resistance in magnetic fields, the phenomenon of supraconductivity is accounted for by the sudden disappearance of the disturbances produced by imperfections in the metal which are the reason for the additional resistance. The advantage of this view is, first, that as the change must take place only in local spots in the metal, no change in the general state of the metal will be required, as actually observed (possibly, if the impurities amount to several per cent, such a change may be experimentally traced). Secondly, we should expect that the threshold temperature would vary with different impurities introduced in the metal. It is evident that on this suggestion it is practically inevitable that all metals at low temperatures will become supraconductors, if the influence of the impurity can be eliminated. I do

not think that there is any experimental evidence that the supraconducting metals form a separate group of elements like the ferromagnetic group or are exceptional in some other ways. We find the supraconducting metals in four groups of the periodic table. They have either a cubic or most irregular lattice; some of them belong to the transition group of elements, and we have amongst them the metals of the highest and lowest melting point. All the special relations between resistance and temperature for supraconductors pointed out by Mr. Bartlett are found by a more minute analysis of experimental data to apply also to some non-supraconductors. The special significance which Mr. Bartlett attaches without any theoretical justification to the fact that all supraconductors have a characteristic temperature below 243° K, probably is no more significant than the fact that the atomic weight of every supraconductor is higher than the 115 of indium, because this happens to be the lightest supraconductor.

Finally, the very important recent discovery made by de Haas (NATURE, Jan. 26, p. 130) that the eutectic alloy of gold and bismuth can become a supraconductor, must be considered very carefully. The details of the experiment are not yet known, but from the point of view which I am defending, the explanation of the phenomenon may be that in a mixture of gold and bismuth one of the metals absorbs more readily the impurities of the other, and this purification may be of such a nature that it allows one of the components to become a supraconductor.

All these considerations no doubt cannot be regarded as final proof of my suggestion, but they offer a definite application of the hypothesis and give a quite fresh experimental line of attacking the problem of supraconductivity.

Mass and Size of Protein Molecules

By means of a method which utilises the measurement of sedimentation equilibrium and sedimentation velocity in strong centrifugal fields at constant temperature, a systematic study of the mass and size properties of the molecules of various proteins has been carried out in this laboratory during the last five years. Our work has been rewarded by the discovery of a most unexpected and striking general relationship between the mass of the molecules of different proteins and the mass of the molecules of the same protein at different acidities as well as of a relationship concerning the size and shape of the protein molecules.

It has been found that all stable native proteins so far studied can with regard to molecular mass be divided into two large groups: the hæmocyanins with molecular weights of the order of millions and all other proteins with molecular weights from about 35,000 to about 210,000. Of the group of the hæmocyanins only two representatives, the hæmocyanin from the blood of *Helix pomatia* with a spherical molecule of weight 5,000,000 and a radius of 12·0 $\mu\mu$, and the hæmocyanin from the blood of *Limulus polyphemus* with a non-spherical molecule of weight 2,000,000, have been studied so far.

The proteins with molecular weights ranging from about 35,000 to 210,000 can, with regard to molecular weight, be divided into four sub-groups. The molecular mass, size, and shape are about the same for all proteins within such a sub-group. The molecular masses characteristic of the three higher sub-groups are—as a first approximation—derived from the molecular mass of the first sub-group by multiplying by the integers *two, three*, and *six*. The molecules of the first and fourth sub-group are spherical, with a radius of 2·2 $\mu\mu$ and 4·0 $\mu\mu$ respectively, while the molecules of the second and third sub-group are non-spherical. Ovalbumin and Bence-Jones's protein belong to the first sub-group; hæmoglobin and serumalbumin belong to the second sub-group; serum globulin belongs to the third sub-group. Rhodophyceæ phycocyan, Cyanophyceæ phycocyan, Rhodophyceæ phycoerythrin, edestin, excelsin, amandin belong to the fourth sub-group in the neighbourhood of their isoelectric points.

The molecules of most of the proteins of the fourth sub-group are easily disaggregated with increasing pH. Thus R-phycocyan at a pH of 4·6 belongs to the fourth sub-group, but at a pH of 6·8 belongs to the third sub-group; that is, its molecules are disaggregated into halves and have lost their spherical symmetry. C-phycocyan at a pH of 4·6 belongs to the fourth sub-group, but at a pH of 6·8 about one-third of its molecules are disaggregated into halves, at the same time losing their spherical symmetry; at a pH of 12·0 the molecules of this protein are probably all reduced to the mass and shape of the protein molecules of the first sub-group, thus regaining their spherical symmetry. R-phycoerythrin at a pH of 4·6 belongs to the fourth sub-group, but at a pH of 11·0 about one-fourth of its molecules are reduced to the first sub-group. Edestin belongs to the fourth sub-group from its isoelectric point pH 5·5 to about pH 10. At a pH of 11·3 a considerable amount of molecules belonging to the second and third sub-group are present together with the normal molecules belonging to the fourth sub-group.

Although not more than 11 different proteins belonging to the group which displays these regularities have as yet been studied, it would seem very improbable that the relationship between the molecular masses and sizes were incidental. Perhaps the most striking proof of the close relations between the different proteins is the fact that one and the same protein may, according to the pH to which it is brought, appear with the molecular mass, size, and shape of another protein.

When looking for an explanation of these unexpected regularities, it would be well to bear in mind the fact already brought out by many bio-chemical experiences, namely, that Nature in the production of organic substance within the living cell seems to work only along a very limited number of main lines. The great variety appears in the specialisation of details. Thus it would seem that the numerous proteins are all built up according to some general plan which secures for them only a very limited number of different molecular masses and sizes when present in aqueous solution. By varying the constituents of the different proteins (different percentage of different amino acids, etc.) the chemical and electro-chemical properties may be varied sufficiently to enable the cells to make use of them for their different purposes.

The experimental data upon which the above conclusions are based have to a large extent been published in the *Journal of the American Chemical Society*. Part of the material is unpublished. The investigations have been carried out in co-operation with R. Fåhraeus, J. B. Nichols, N. B. Lewis, E. Chirnoaga, F. Heyroth, B. Sjögren, T. Katsurai, A. J. Stamm.

Rate of Decay of Polonium in Different Points of the U S S R

THE half period of a radioactive element characterises the rapidity with which it decays If the classical theory of the spontaneously exploding atom be accepted this rate should be the same at any point of the earth's surface

In order to verify this assumption, measurements of the half period of polonium have been made during the past two years Polonium was chosen for this purpose, as the most convenient radioactive substance for observations of this kind, because it is easily obtained in a pure state, its half period can be directly observed ($136\ 5 \pm 0\ 3$ days), and it is also the last radioactive member of the uranium series

In these experiments polonium was deposited electrolytically on accurately polished gilt brass discs of 75 mm diameter to avoid the possibility of the oxidation of metallic surface Discs having small rims were supplied with round covers which safely protected the active layer from mechanical effects The process of carrying out the experiments was as follows The discs were carefully measured by means of a compensating electrometric set which allowed their activity to be determined through the magnitude of the ionisation current with an accuracy of 0 2 per cent The set itself was verified by means of a uranium standard Just after this measurement the active discs were packed, sealed up and sent by post to a number of places, where they were kept according to instructions in the Local Weights and Measures Offices which are under the management of the Central Chamber of Weights and Measures

After an interval of about five months, packets containing the discs were returned to Leningrad and were immediately measured for the second time The half period was calculated according to the formula expressing the rate of decay $I_t = I_0 e^{-\lambda t}$, and to the equation $T = \log 0\ 5 \times I/\lambda$ where I_0 is the initial activity before sending to the points I_t, the activity after the receipt in Leningrad, t, the time between two measurements, λ, the radioactive constant, and e the base of natural logarithms

The determinations of the half periods were made at eighteen points corresponding to eighteen towns, namely, Murmansk (1), Archangelsk (2), Leningrad (3), Vologda (4), Kazan (5), Moscow (6), Samara (7), Kursk (8), Saratov (9), Charkow (10), Rostow/Don (11), Odessa (12), Astrachan (13), Krasnodar (14), Wladikaukas (15) Tiflis (16), Baku (17), Erivan (18)

The most northern point was Murmansk (68° 59 N) and the most southern one was Erivan in Caucasus (40° 11 N)

All the points were distributed through a distance of 3000 km along the meridian The results obtained show that the rate of decay of polonium is far from being equal in all points The value of the period changed from 125 6 days (Tiflis) to 181 6 days (Krasnodar) A significant reduction for Astrachan gave the value 127 8 days The average least square error of the observations did not surpass 0 7 per cent

From the results obtained we reach the conclusion that, taking into consideration the absence of influence of the metal, which could only reduce the value of the half period, local conditions had an influence upon the rapidity of radioactive decay

To verify our assumption, the determinations of the half period were repeated for all eighteen discs after they had lain about five months in Leningrad The values of the period thus found varied from 137 2 to 139·5 days, which is not outside the limits of observation errors On the accompanying diagram (Fig 1) curve A shows the values of the half period in different places, and curve B the values of the half period in Leningrad

The experiments described are preliminary only, and the investigation will be undertaken on a larger scale with the view of determining without any doubt the influence of local conditions upon the rate of decay of radioactive elements

This phenomenon can be easily explained, if we admit Perrin's theory assumption of the existence of an external source of radiant energy which produces the radioactive decay of atoms If we admit the existence of this source in the centre of the earth,

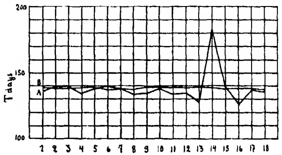

FIG 1

the rapidity of the decay must be influenced by the quantity of radioactive substance which is included in the great bulk of the basic rock The greater the quantity, the less must be the decay in this place because of the absorption of radiant energy, causing the radioactive decay of heavy atoms, by radioactive elements in the underlying layers

In favour of this assumption also, we have the fact that the greatest deviations of the period occur in places with disturbed tectonics, that is, in the places situated in Caucasus and the region adjoining it, on its northern boundary

Thyroid and Temperature in Cold-blooded Vertebrates

THIS problem which Prof Huxley discusses in NATURE of May 11, p 712, is a very intriguing one To me it appears to have more difficulties than Prof Huxley allows for He begins by saying that "it is well known that the thyroid is concerned with temperature regulation in homothermic animals" In my recently published book, "Fever, Heat Regulation, Climate, and the Thyroid Adrenal Apparatus", I have reviewed the very scanty and contradictory literature on this subject, and one could scarcely say that the relationship of the thyroid gland to heat regulation has been previously either well known or well understood I dare scarcely hope that my own views on the problem as set forth in a book published only a year ago have already been assimilated so completely as to have become a commonplace of scientific literature

In the book mentioned I directed attention to the difficulties of the problem discussed by Prof Huxley In warm blooded animals a change of the thermal environment from heat to cold stimulates the thyroid and adrenal glands to increased activity, and there is a rise in general metabolism Exposure to heat produces the opposite effect it induces a resting condition in the thyroid and adrenal glands and the metabolism is lowered The resting condition of the

thyroid gland is indicated *inter alia* by an accumulation of colloid in the thyroid vesicles Now in cold blooded animals exposure to cold produces a fall both in the temperature of the tissues of the animal and in the metabolism, while heat raises both One might expect that a fall in the temperature of the animal as a whole would diminish the activity of its organs, including the thyroid gland In that case the interesting conclusion would follow that in the course of evolution the response to an environmental stimulus in a specific group of cells has been completely reversed although the cells have not changed their specific character

Prof Huxley's suggestion is that the thyroid of cold blooded animals, like that of warm blooded animals, is stimulated by cold and inhibited by heat This would imply that while the temperature of the animal as a whole falls and the activity of its organs diminishes, one particular organ—the thyroid gland—has a greater functional activity at a lower temperature than at a higher temperature One cannot exclude *a priori* such a possibility because it appears to be paradoxical But it requires more convincing evidence for its support than Prof Huxley adduces from his own experiments The statement attributed to Adler that in tadpoles low temperature caused hypertrophy of the thyroid gland both in growth and functional activity is open to the criticism that in warm blooded animals increased functional activity does not manifest itself by hypertrophy

In conclusion, it may be pointed out that the whole problem is further complicated by the fact that in warm blooded animals the adrenal gland plays a very important part in the heat regulating mechanism, this gland acting synergically with the thyroid gland There is a striking parallelism between the development of the heat regulating mechanism and the evolution of the adrenal gland as expressed in the changing anatomical relationship of the two histogenetically distinct tissues which in the mammals form cortex and medulla This must be taken into account when differences in the heat regulating mechanism of cold blooded animals is being discussed

Variation of Latitude with the Moon's Position

IN NATURE of Jan 26, 1929, p 127, Prof H T Stetson has described a variation of latitude with the moon's position, and in the *Comptes rendus de l'Académie des Sciences* of July 30, 1928, A Gougenheim has described a variation of latitude with the

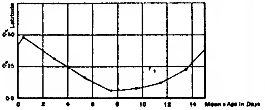

FIG 1

age of the moon In October and November 1926 a series of observations of the latitude of Dehra Dun (India, Lat. 30° N) were made with a prismatic astrolabe, which show a clear relation between the latitude and the age of the moon (Fig 1), but no relation at all between latitude and moon's altitude (Fig 2) The variation with the moon's age was about one third of that found at Algiers, and was apparently in phase with it

The fact that the astrolabe at Dehra Dun shows no variation with moon's altitude does not of course

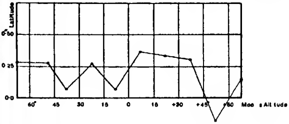

FIG 2

invalidate deductions made from Prof Stetson's more precise and extended series, but it seems surprising that the fortnightly variation (if it truly exists) should be larger and more easily measured than the daily variation

Each point in Fig 1 represents about 10 series of observations, each lasting about two hours and giving apparent probable errors of 0″ 3

Survey of India, Dehra Dun

A New Titanium Band System

THE dominant feature of the *M* type stars is the very extensive group of titanium oxide bands beginning in the blue region of the spectrum and continuing far to the red The group of bands occurring in the blue green region has been analysed (see Christy and Birge, NATURE, 122, 205 , 1928), and shown to be due to a $^3P - ^3P$ transition of neutral titanium oxide

Bands in the red portion have been observed by many investigators and especially by P W Merrill, who found that those of the λ7054 λ7700 region are particularly intense in *M* type spectra Twenty bands, including in all 46 heads, extending from λ7990 to λ6270, and partially overlapping the above group, have now been assigned to a new system The lower level is the same as that of the former system in the blue green This, and the fact that both systems appear in absorption in stellar spectra, show that the two are resonance systems The frequencies of the heads of the new system are given by

$$\left.\begin{matrix}14172\ 2\\ 14105\ 8\\ 14030\ 8\end{matrix}\right\} + (862\ 5n' - 3\ 84n'^2) - (1003\ 8n'' - 4\ 61n''^2)$$

with an average residual of 1 cm $^{-1}$ As shown by the formula, the mean separation of the heads is 70 7 cm $^{-1}$ The mean separation of the lower levels of the blue green system was shown indirectly to be about 70 cm $^{-1}$ (see *Phys Rev* , May 1929), indicating that the upper level of the new system is single Each of the three heads of the more intense bands has a clearly marked secondary head at about 10 cm $^{-1}$ to the red These latter heads are formed presumably by the *Q* branches Since transitions between singlets and triplets are very uncommon in band spectra, the upper level is in all probability a ^3S

The values of ω_0'' and $\omega_0''x''$ (that is, 1003 8 and 4 61) are believed to be somewhat more accurate than those published previously, and are based on the mean separation of levels as found from both systems Using the new values and assuming a linear extrapolation, the heat of dissociation for the lower level is found to be 6 74 volts The total energy resulting

from the dissociation at the other two levels is also about 7 volts There are still a few bands in the region λ6270 to λ5600, overlapping both systems, which remain unassigned Their general appearance is different from that of the bands in either analysed system

Mimicry

THE objections to natural selection and chance variation raised by my friend Prof E W MacBride in NATURE of May 11, are those expressed by Asa Gray and answered by Darwin, when in 1867 he sent the advanced sheets of "Variation of Animals and Plants under Domestication" to the great American botanist The creative power of natural selection is explained by a metaphor

"If an architect were to rear a noble and commodious edifice, without the use of cut stone, by selecting from the fragments at the base of a precipice wedge formed stones for his arches, elongated stones for his lintels, and flat stones for his roof, we should admire his skill and regard him as the paramount power Now the fragments of stone, though indispensable to the architect, bear to the edifice built by him the same relation which the fluctuating variations of organic beings bear to the varied and admirable structures ultimately acquired by their modified descendants"

Now apply Prof MacBride's argument to Darwin's metaphor Why are certain stones selected ? Because they are the fittest" Certainly 'How do we know that they are the fittest ? Because they are selected" Obviously absurd

Again referring to 'chance' or 'accident', Darwin wrote 'The shape of the fragments of stone at the base of our precipice may be called accidental, but this is not strictly correct for the shape of each depends on a long sequence of events, all obeying natural laws But in regard to the use to which the fragments may be put their shape may be strictly said to be accidental"

With regard to birds as enemies of butterflies, the necessities of space prevent me from doing more than refer Prof MacBride to the publications of the Entomological Society of London, where he will find much evidence of serious attacks as well as numerous isolated examples

In reply to Dr Carter's interesting letter, I would point out that the behaviour of an insect eating animal may suggest processes essentially similar to the simpler reactions of man A chameleon once stung by a honey bee would never touch another The association and memory were perfect after a single lesson It must be remembered, too, that mimicry is especially characteristic of forest butterflies where the alternation of sunlight and shadow renders the imperfect resemblance of a flying insect far more effective than it would be in uniform light or shade

Oxford, May 24

Another Species of Monœcious Oyster, *Ostrea plicata* Chemnitz

IT was noted by me in 1926 (*Proc Roy Phys Soc*, vol 21, Part 2, 1926) that the different species of *Ostrea* can be grouped into two categories, the monœcious and the diœcious I also enumerated several fundamental points of difference between them morphologically and physiologically Later in 1928, J H Orton in NATURE, Mar 3, 1928, put more emphasis upon the distinction of the two categories

There are more than sixty species of *Ostrea* distributed all over the world The greater part of them are diœcious, while the recorded species of the monœcious oyster are not many The first four species given below have already been recorded as having every character of a monœcious species

I here introduce one more species of the monœcious category which has not yet been recorded as such, namely, *O plicata* Chemnitz, or *O plicatula* Gmelin, the latter being probably the synonym of the former There are therefore five species now known to be monœcious *Ostrea*, as follow

O denselamellosa Lischke, the Japanese species
O edulis Linn, the European species
O lurida Carpenter, the British Columbian species
O angasi Sowerby, the Australian species
O plicata Chemnitz

The present species is found on the east coast of Japan It is by no means very rare, yet it has not attracted much attention of biologists or laymen, as its size is always rather small The species can attain sexual maturity in one full year, showing 'white sick' and 'black sick' stages, as is typical for the monœcious habit The size at maturity is only three centimetres in the longest diameter Even the largest specimen rarely attains more than six centimetres

Television Inventions

IN NATURE of April 27, p 637, a notice appeared of a book by Mr C Francis Jenkins, of Dayton, Ohio, entitled 'Radiomovies Radiovision, Television" With some difficulty I have obtained a copy of this book from America, and find in it, in a picture which appears to be on page 74 (though no paging is given), a description copied from a journal of July 25, 1894, ascribing to C Francis Jenkins an apparatus for transmitting pictures by electricity, under the name of the Jenkins' Phantoscope This is identical in all essentials with the method of television proposed by G R Carey, an American, and dated 1875 according to "La Television Electrique", by A Dauvillier, published much later, in 1928, by *La Revue Generale de L'Electricite*, of Paris, while an illustrated description of Carey's method also appears in a copy I possess of *Design and Work* for June 25, 1880

These discrepancies in dates are worthy of notice, as is also the suggestion in "Television", by Alfred Dinsdale (editor of the *Television* magazine), published so recently as 1928, that Baird's transmitter was the first means by which real television was achieved, a means illustrated by apparatus at present on view in the Science Museum, South Kensington, in which the picture was formed piece by piece by passing light through staggered apertures in rapidly revolving discs, but which was, according to Dauvillier's very comprehensive survey of television inventions, actually patented by Nipkow, a German, so long ago as 1884, some forty two years before the arrangement was attributed to Mr J L Baird, that is to say, actually five years before Mr Baird appears, from "Who's Who", to have been born

Down House and Darwin

DOWN HOUSE, the home of Darwin from 1842 to 1882, now vested in the British Association in custody for the nation, was formally dedicated to the public access on June 7 A distinguished company of members of the General Committee of the British Association, representatives of Darwin's family and of societies to which he belonged, and other invited guests, listened to the short ceremony at which Sir William Bragg, president of the Association, was in the chair, and Sir Arthur Keith was the principal spokesman

It will be remembered that Sir Arthur Keith, at the conclusion of his presidential address on the present position of Darwinism, at the Leeds Meeting of the Association in 1927, put forward a plea for the preservation of Down House This was promptly answered by Mr Buckston Browne, F R C S, who (in brief) bought the property, gave it to the Association with a generous endowment, has fully restored the whole house, and has brought back the ground floor as nearly as possible to its condition in Darwin's time, presenting many appropriate objects of art from his own collection Truly a noble benefaction, and one which imposes new and welcome duties upon an Association which should prove itself peculiarly fitted for discharging them The nearest parallel to them is found in the Association's action in 1842, when it saved Kew Observatory from being diverted from scientific use, and sustained the burden of its maintenance for thirty years Down House, however, will be no burden, but a very honourable trust

FIG 1 —Darwin's house at Down, Kent

Those whose minds find no appeal in the sentiment underlying the establishment of this memorial to one of the greatest of all leaders of research cannot be otherwise than an insignificant minority To the many it will mean more than a little to recapture, as they still may, the atmosphere in which Darwin, in the words of the inscription now erected beside his entrance gate, ' thought and worked for forty years " They may view the ' old study ' in which the " Origin of Species " was written, and others of his rooms, restored with much of his own furniture and articles of use, which have been sent back to their place by members of his family and other generous donors They may pass through his gardens (in the restoration of which the Association has no small task before it), they may follow him around the Sand Walk and still enjoy, as he did, the view across the pleasant valley towards the Sow Wood, as yet untouched by the builder or any other modernising influence save the gentle intrusion of a golf course, and here is indicated a further justification for the preservation of the property A pamphlet issued by the Association for distribution to visitors quotes a description of the neighbourhood as intensely rural and quiet though only sixteen miles from London Bridge ", and points out that Down still preserves these characteristics It may well be that in the future, as the outer circle of London extends, the preservation " of the estate ' will be regarded as an æsthetic blessing only less than as a dutiful tribute " to Darwin's memory

Behind these considerations, however — one fundamental, the other at least powerful—there arises the hope that the estate may be put to use for the direct benefit of science The attainment of such an object is present in the minds of the donor, of the members of the Down House Committee which the Association has appointed for the management of the property, and of others besides No plan has as yet taken definite shape , none could or should be given effect in a moment But it is not difficult to envisage more than one direction in which this idea—rather, this ideal—could be realised Meanwhile, when it is realised that the property was only vacated by the previous tenant six months ago, the condition of the property remarkably attests Mr Buckston Browne's generosity and enthusiasm A most distinguished American biologist has characterised his action as " initiating one of the most splendid movements of all time " An American committee has been appointed to co-operate with the Association's committee, especially in endeavouring to recover Darwiniana now in America There are those who look forward to Down as a scientific Stratford on Avon for future generations So may it be

The British Eclipse Expeditions of May 9, 1929

By Prof F J M STRATTON

BY the time these notes appear in print the facts on May 9 will be known of the eleven expeditions from France Germany Great Britain Holland Japan and the United States which are at present scattered on the line Sumatra—Kedah—Siam—Cambodia—the Philippines News can only be supplied here of the Japanese expedition under Prof Sotome to Titra in Kedah of the German expedition under Dr Rosenberg to Khoke Bhodi in Siam and of the two British expeditions to Alor Star in Kedah and to Pattani in Siam In all cases it can be said that preparations are well in hand attended so far by no serious delays or troublesome mischances

FIG 1 —British observers camp at Pattani

Shelters of atap palm in many cases supplemented by canvas or other linings to get the effect of a double roof cover the instruments preliminary adjustments are made and weather conditions do not seem likely unduly to hinder the final adjustments So far as can be gathered by comparison with present weather conditions prospects are most favourable at Pattani their Majesties the King and Queen of Siam are to visit the British camp there for the eclipse as in 1875 the then King of Siam observed the eclipse from Sir Arthur Schuster s camp

In Kedah the Resident Adviser to the Regent has done everything to facilitate the work of the expeditions Dr and Mrs Jackson are staying at the Residency and the eclipse camp is close by The necessary electric current required for Dr Carroll s comparison arc spectra and for the mercury lamp to be used by Dr Aston for the interferometer has been obtained from the town mains and through the kindness of the Regent all constructional work required has been done by the P W D Photographic troubles have been largely met by the kind permission of the medical authorities to make use of the dark room facilities at the local hospital

In Siam the conditions are much more difficult but the Siamese authorities have done everything possible to facilitate the work of the observers At each place the Government has erected a hut camp with mess room office kitchen six rooms and servants quarters lit by electric light All constructional material required and labour have been supplied arrangements made to guard the eclipse camps and to meet the requirements of the observers in the matter of electric current by the provision of portable electric plants His Majesty the King of Siam appointed a special reception committee charged with the duty of helping the astronomers in every way and right well have they carried out their allotted task All the local authorities in their turn have added to the obligations that the expeditions are under to the Siamese people Photographic difficulties are not

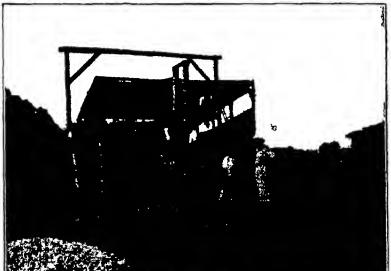

FIG 2 —Telescope in position at Pattani

insuperable, though real, in this hot climate A good deal can be done to meet them with ice from the local factory, and an efficient cooling plant, specially designed to meet the requirements of an eclipse dark room, should make matters still easier by providing a good supply of cooled water

Most of the personnel for the actual observations have already arrived, but special mention must be made here of the services to the British expeditions of their honorary secretary, Col J Waley Cohen Not only did he thoroughly explore both sides of the peninsula in 1928, bringing back valuable information as to meteorological conditions and as to local possibilities for eclipse preparations—and incidentally he interested many influential people in the coming eclipse—but he also arrived in the East this year ahead of the observers and made all the preparatory arrangements, so that a great deal was already done and in hand when they arrived At Pattani, Col Waley Cohen has also continued to relieve the scientists of the expedition of all worries about such matters as messing, local financial arrangements (not easy when there is no bank within many hours' journey of the camp), and the multitudinous details which have to be attended to, if matters are to go smoothly

The accompanying photographs, taken by Dr Royds, director of the Kodaikanal Observatory, show (Fig 1) the special camp erected for the observers to live in, and (Fig 2) the astrographic telescope from Greenwich in course of erection with Mr P J Melotte's instruments, including a coronagraph of 19 ft focal length with a direct vision prism for the first and second flash, three spectrographs, and a double tube camera with a Nicol prism in front of one object glass for a polariscopic study of the corona The party of the observers and assistants on the day of the eclipse will be twelve In addition to those above mentioned and myself, Prof F Barnes and W F Kibble, of Madras, have already been at the camp for some days and given valuable help

Einstein's and other Unitary Field Theories An Explanation for the General Reader

By Prof H T H PIAGGIO

II

GEOMETRY ON A SPHERE

THE leading ideas of the geometry that Einstein chose (Riemannian) can be made clear by considering the properties of a geographical globe (Fig 1) on which are marked the meridians and parallels of latitude These divide the surface into what we may call curvilinear rectangles But these rectangles are not all of the same size or shape For consider two points with the same latitude but with longitudes differing by one degree The distance between them depends upon the latitude, it is greatest at the equator and zero at the poles Thus APB is greater than DQC For a sphere the distance between two points with the same longitude (i e on the same meridian), but with latitudes differing by one degree, is constant, but if our globe (like the earth itself) is flattened at the poles, this distance will again depend upon the latitude

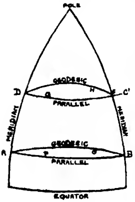

FIG 1

In either case, we cannot find the distance between two points A and C on the globe merely by knowing the *differences* of their latitudes and their longitudes, whereas in a plane the distance between two points is determined solely by a knowledge of the differences of their x and of their y co ordinates This is what is meant by the rather alarming statement that the sphere has a Riemannian metric, while the plane has a Euclidean one (In mathematical symbols, $ds^2 = dx^2 + dy^2$ shows a Euclidean metric, but $ds^2 = g_{11}dx^2 + g_{22}dy^2$ shows a Riemannian metric, provided that g_{11} and g_{22} are functions of x and y, or of either of them)

It is not only a plane that has a Euclidean metric Take a piece of squared paper, and roll it up, or bend it (without stretching or tearing) into as queer a shape as you please The squares drawn on it remain all of the same size as before, hence the metric is still Euclidean Such a surface is said to have zero *Gaussian curvature*, although it is what an ordinary person would call curved The real distinction between it and a sphere is that the squared paper can be flattened out again, whereas it is impossible to flatten out a sphere or a piece of it (as may be easily verified with a piece of a broken rubber ball) Another way of putting this is to say that any attempt to make a flat map of the earth must be imperfect and give a distorted representation, as is obvious on Mercator's chart near the poles

A well known problem in geography or navigation is to determine the shortest route that can be traversed between two points on the earth's surface On a model globe we can determine this experimentally by stretching a piece of string between these two points It will be found that it will lie in what is called a *Great Circle*, namely, one the plane of which passes through the centre of the earth It is important to notice that it is not the same as a parallel of latitude In fact a ship that has to sail between two points A and B on the same parallel APB (north of the equator) will, to follow the Great Circle AGB, have to sail north of this parallel and then come back to it, a method rather tiresome to navigators, as it entails a continual change of direction (as measured by compass bearing) A Great Circle on a sphere has one of the properties of a straight line in a plane, namely, that of being a *geodesic* or shortest distance between

two points on it but not (in general) another that of having a constant direction This may be considered to belong to a route that makes a constant angle with the meridians it is called by navigators a *rhumb line* or *loxodrome* They often use it in spite of it not being a geodesic because it preserves a constant compass bearing which can be determined at once by drawing a straight line between the two positions as marked on Mercator's chart It is important to notice that what we here call constant direction on a sphere is defined by reference to compass bearing or Pole star or axis of rotation (through which the meridians pass) each of which is really quite independent of the geometry of the sphere itself and to that extent is arbitrary

GEOMETRICAL BASIS OF EINSTEIN'S GENERAL THEORY

Einstein's General Theory may now be stated broadly as the assumption that the physical geometry of space time is one which has a Riemannian metric and a curvature and in fact is somewhat analogous to geometry on a sphere The analogy is made closer if we replace the sphere by a surface like a hen's egg of which the curvature is variable If the egg has been hard boiled and then deprived of its shell so as to be flexible the analogy is still further improved for the Gaussian curvature and Riemannian metric which depend only on a network of curves drawn on the surface and deformable with it are the properties with which Einstein is concerned It is important to notice that no account is taken of any measurements except those made *on* the surface which from this point of view is a two dimensional region

The non mathematical reader may however say How can two dimensional results on a sphere or egg which everyone can imagine be applicable to four dimensions which are inconceivable? The answer to this is that the symbols used by mathematicians have the valuable property that they enable us to work largely by analogy in four dimensions almost as easily as in two The merit of Riemannian geometry which to those unfamiliar with it may appear rather complicated is that in it the physical laws of the motion of a planet or of a ray of light are the simplest possible namely that they are geodesics By stipulating that the paths must be very nearly those given by Newton's law of gravitation we get some indication of how to determine the coefficients in the Riemannian metric To determine these fully requires other considerations too lengthy to enter into here

As is now well known this theory has been strikingly successful not only in explaining a known fact the anomalous motion of the perihelion of the planet Mercury but also in predicting successfully the effect of a strong gravitational field on the bending of light and the shift of spectral lines Eclipse expeditions speedily confirmed the first prediction but the second was originally denied by experimenters The spectral shift is now admitted to exist and the minute effects due to the sun have been supplemented by the more easily observed effects due to the dark star of enormous density called the Companion of Sirius

PHYSICAL BASIS OF THE UNITARY FIELD THEORIES OF WEYL EDDINGTON AND EINSTEIN

We have seen that the Special Relativity theory is fundamentally an electromagnetic one while the General Theory is fundamentally gravitational After constructing a geometry of space time specially chosen so as to explain gravitation in a simple manner Einstein found that electromagnetism could be fitted into the scheme but could just as well be left out Now this is scarcely satisfactory Gravitation and electromagnetism are both physical phenomena and why should one be considered as an essential property of space and the other as only an accident? Was the world constructed solely for the requirements of gravitation and then part of it let off to electromagnetism as a lodger? The obvious thing seemed to be to modify the Riemannian geometry so that it would serve gravitation and electromagnetism equally well

GEOMETRICAL BASIS OF WEYL'S UNITARY THEORY (1918)

Einstein had made gravitation appear as a natural consequence of replacing Euclidean geometry by Riemannian in which the geodesics lose their property of preserving a fixed direction Weyl proposed to replace Riemannian geometry by another in which the idea of length is also given up In his theory at any rate in its original form the length of a rod altered every time it passed round an electric current This theory certainly gave some interesting mathematics in which equations of the form of Maxwell's electromagnetic ones made their appearance but as it has received no experimental confirmation whatever it need not be considered very seriously

EDDINGTON'S UNITARY THEORY (1921) AS A GRAPH

Weyl's geometry formless as it seemed still retained one definite property of which Eddington promptly proceeded to divest it We shall not enter into details because Eddington avowedly is not claiming to construct a physical theory but only an illustration or graph which may be looked upon as a device useful in enabling us to grasp certain mathematical relations He hoped it might throw light on the nature of the forces which prevent an electron from exploding but up to the present it does not seem to have done so

Eddington considers that not only his own unitary theory but also Weyl's and Einstein's are graphs However from Einstein's own words— my opinion is that our space time continuum has a structure of the kind here outlined —it would appear that it is claimed to be a genuine physical theory

EINSTEIN'S UNITARY THEORY (1928–29)

Whereas Weyl and Eddington replaced Riemannian geometry by others still more unlike Euclidean, Einstein has now, in part, returned to more ordinary ideas His geometry is one which possesses *distant parallelism* as well as a Riemannian metric To explain what is meant by distant parallelism, we return to our two dimensional analogy Cover our hen's egg, or any other surface, with a network of curvilinear rectangles' 'Parallel directions' are defined as those which make the same angles with corresponding sides of the local rectangles This definition leaves the original choice of the network undefined, but we saw that on a sphere direction had to be defined by some thing, like a magnetic compass or a pole star, which was not a property of the sphere itself, and so in a certain sense undefined by its geometry alone

Perhaps Einstein's parallel directions may be ultimately defined in terms of dynamics He may even get back to the position of Newton, who conceived absolute rotation to be a real thing, which could be detected by seeing whether the surface of a fluid was a paraboloid of revolution or a plane The behaviour of Foucault's pendulum and of gyroscopes certainly seem to furnish us with a dynamical definition of direction

By using our sphere, we may even give some idea of the actual function that Einstein takes to measure what may be called electromagnetic potential Suppose a boat has two short trips, each of one mile, one east and the other north By sailing first one mile east and then one mile north, let us reach a point C By sailing first north and then east we reach a different point C′, since the parallels of latitude get smaller as we go north (see Fig 1). The distance CC′ represents Einstein's potential This illustration is not exact, because on a sphere CC′ is very small compared with the distances AB, BC, whereas in Einstein's theory it is essential that it should not be so To illustrate this we should have to suppose our sphere to have a crinkly surface

If we now take the corresponding construction for three dimensions, the result is rather queer If AB and DC are parallel' paths, the path from B 'parallel' to AD will not intersect DC It is properties of this kind that Eddington finds unattractive, but they are essential to the electromagnetic part of the theory

Of course the ultimate test of the theory must be by experiment It may succeed in predicting some interaction between gravitation and electromagnetism which can be confirmed by observation On the other hand, it may be only a 'graph' and so outside the ken of the ordinary physicist Einstein's paper points out that so far there has not been time to examine the full consequence of his equations

Even supposing the theory fully established, there are still fresh worlds for Einstein to conquer The quantum theory remains outside his scheme He made an attempt to deal with this so far back as 1923, but without any striking success However, it has been suggested that the postulate of distant parallelism will enable the unitary theory to take over Dirac's theory of a spinning electron almost unchanged

The Detection of Helium

THE natural facility with which the radioactive elements disintegrate has led on one hand to attempts to break down atoms artificially, and on the other to build them up from simpler particles Rutherford succeeded in conveying the necessary energy to some of the less massive atoms and broke them down by bombardment with sufficiently energetic α rays, atom by atom at comparatively rare intervals the process of atom building is still not more than a dream, realised perhaps in the depths of space as Millikan has suggested in order to account for cosmic rays

The production of gold from mercury, and many another attempted transmutation, have proved, to put it mildly, apparent rather than real changes In the case of the experiments in which helium was supposedly formed in some way or another by an electric discharge, there has lurked for a long while a certain feeling of unsatisfactoriness Prof Paneth's recent work goes far to dispel this feeling (see *Zeits f phys Chem*, **134**, 353, 1928, and **1**, 170 and 253, 1928) The outcome is indeed satisfactory those that found helium have reason to have got it, those that did not might well have found it, and been misled perhaps as to its origin

Paneth and Peters show that helium is the only gas which at ordinary temperatures can diffuse through glass At a pressure of 0 5 atmosphere 10^{11} c c of helium will pass through a thickness of 0 5 mm of soda glass per cm ^{2} per hour The amount of helium that gets through from the air at ordinary pressure into an evacuated glass vessel (1 mm wall thickness) is 10^5 times less, so that a glass apparatus is for all practical purposes 'tight' at ordinary temperatures When warm the rate of diffusion through the glass is much greater (cf Lo Surdo, *Atti R Accad Lincei*, **30**, 1, 85, 1921) A hard glass tube 1 5 mm thick at 500° C lets through 10^{9} c c of helium from the air per cm ^{2} per hour Helium, indeed, can be separated from neon and other gases by diffusion through hot glass It is otherwise with palladium Helium will not diffuse through palladium at a red heat A mixture of helium and hydrogen can be separated completely by diffusion of the hydrogen through a palladium capillary, the quantity of helium that gets through is not even 10^{12} of the quantity of hydrogen that passes Helium and neon are found in the gases absorbed by glass which has been in contact with air, but the gas is considerably richer in helium than in neon On the other hand, if there is a minute flaw in the glass or at a tap, causing a leak however small, the neon and helium found in the residual gases remain in the same proportion as

they exist in the air approximately 3 1 (It is noteworthy that Paneth and Peters found that good taps could be relied on not to leak if properly ground and greased their apparatus was therefore not made tap free Twenty taps standing 48 hours had not leaked to the extent of more than 10^{6} c c air equivalent to about 10^{10} c c Ne and He) It can be shown that a vacuum tube which becomes heated by a discharge will contain afterwards traces of helium if it is not protected from access of air externally however great other precautions may have been taken to prevent ingress of air A double wall is not even sufficient if both become warm It is necessary to immerse the tube in water or in oil which cools and at the same time seals the glass The presence or absence of helium in the residual gases is therefore mainly a question of the temperature of the walls of the tube and the sensitiveness of the method of detection

Paneth gives 10^{12} to 10^{11} c c as the limiting volume of helium which can be detected spectroscopically This means that in his apparatus the helium and the neon in about 10^{5} c c of air can be detected—a limit about 100 times smaller than that given for the method used by Strutt (*Proc Roy Soc* A **89**, 499 1914) A careful study is made of the quantity of gas required to bring out the various spectral lines for the pure gases neon and helium and their 3 1 mixture obtained from atmospheric air The spectra of the gases are examined using a capillary tube about 0 1 mm bore the fine capillary makes it unnecessary to use a slit with the spectroscope Excitation is provided by external electrodes The results enabled estimation of very minute quantities of the gases to be made without recourse to uncertain volume measurements in fine capillary tubes For quantities at the limit of detection (10^{10} c c) only the 5875 and 5015 lines of helium are visible and only the 5852 line of neon The latter masks the 5875 helium lines in a mixture of the two gases and only 5015 remains visible Paneth succeeded in this way in measuring the quantities of helium (about 10^{8} c c) generated by only about 40 grams of thorium in 113 days taking very special precautions to prevent contamination with helium from other sources Even with every precaution a trace of neon was also detectable

Either calcium or an electrically heated spiral of palladium were employed for removing large quantities of hydrogen from the gases under examination for smaller quantities combustion with oxygen at the surface of palladium sponge was used The gases were taken from place to place along with oxygen which was afterwards removed by absorption with cooled charcoal the residual rare gases being run up into the capillary tube for the spectroscopic test Special precautions were taken to prevent any rare gases being present in the electrolytically generated hydrogen and oxygen used throughout the work these latter were shown to contain less than about a millionth of a per cent of air All parts of the apparatus with large glass surfaces and those subjected to heat were vacuum jacketted and then immersed in water

Paneth and Peters have bombarded salts of potassium they have run a heavy discharge through hydrogen between aluminium electrodes at pressures from 1 to 85 mm and also between a palladium spiral electrode through which a large quantity of hydrogen was diffused without obtaining any helium or neon other than traces from ascertained sources They have tried a powerful silent discharge through hydrogen at 10 to 760 mm pressure and they have passed a heavy discharge through paraffin examining the hydrogen so generated In all cases the results were negative provided the glass was protected from transfusion by helium from the air In spite of the stability of helium and the possibility of building it up from protons and electrons with evolution of 7×10^{11} cals per mol these experiments show that even with a favourable high concentration of hydrogen the amount of helium so formed is certainly less than 10^{9} c c The same result applies to the production of helium by bombardment of water and of mercury with β and γ rays To these experiences have to be added those of Allison and Harkins (*J A C S* **46** 814 1924) in which very heavy discharges were employed yet with no positive effects Considering too that the sensitiveness of detection in Paneth and Peters work is claimed to be 10^{4} times greater than the volumes of helium and neon obtained in those experiments by other workers which have appeared to give positive results (*e g* production of helium from salts of potassium where the quantity found was between 10^{5} and 10^{6} c c) it is fairly definite that their source must be other than permitted by Paneth s arrangements and precautions

One of these sources when helium is alone found is no doubt the diffusion of helium through heated glass (or quartz) It is interesting to note that this was also the conclusion of Masson in his experiments with the quartz mercury arc (*Proc Roy Soc* **91** 30 1915) It is noteworthy that Paneth found that glass which is exposed to air contains helium and less neon (50 cm^{2} of glass holds more than 10^{8} c c He) Hydrogen greatly assists the removal of these adsorbed gases Oxygen however, has practically no effect in washing them out of the glass Heating alone without washing with hydrogen is also comparatively ineffective This fact seems also to explain some features of the earlier work Prof Paneth s work has gone a long way to clear up the unsatisfactory state in which this subject had been left There is now no evidence for the formation of the rare gases by the discharge, but very definite reasons for their detection in the kind of experiments which were carried out (*e g* presence of He in X ray tubes as found by Ramsay (NATURE **89** 502 1912))

Passing from experimental work of a critical nature to that with a more constructive object, Paneth has utilised his methods of detection of minute quantities of helium in connexion with a variety of other problems (see *Zeit anorg Chem*, **175** 383 1928, and *Zeit f Elektrochem*, **34** 645, 1928) Amongst them may be mentioned the origin of the abnormal helium content of sylvin and beryl,

the quantity and origin of helium in gases of natural origin and the helium content and age of meteorites At Ahlen in Westphalia a source of natural gas has been found to provide about 40 m^3 per day containing 0 19 per cent helium but this does not compare with the source at Calgary in Canada 330 000 m^3 per day containing 0 33 per cent He or with that at Petiola in Texas 425 000 m^3 per day of 0 9 per cent The ages of the various iron meteorites investigated are found to range from that of the Savic meteorite (8000 years perhaps) to the hoariness of the Nelson Co meteorite comparable to the age of the earth ($2 6 \times 10^9$ years) It is thought that passage near the sun might account for the removal of helium from the Savik meteorite making it appear more youthful than it is really likely to be

Another interesting direction of Prof Paneth s work was in the attempt to prepare helides after the manner in which he has so successfully made hydrides of various elements No trace of the formation of helides of arsenic antimony lead germanium selenium iodine and chlorine was obtained In the experiment with chlorine the merest trace of the formation of a helide would have been detectable It is considered that such helides as can be formed can only have a very fugitive existence of the order of 10^{-8} second

One might recall the words of Leonardo da Vinci in connexion with all this illuminating work Experience is never at fault it is only our judgement that is in error in promising itself such results from experience as are not caused by our experiments A C F

Obituary

George Birtwistle

GEORGE BIRTWISTLE was born at Burnley in 1877 Educated at Burnley Grammar School and Owens College he won an open scholarship in mathematics at Pembroke College Cambridge in 1895 He was bracketted Senior Wrangler in 1899 and was placed in Class I Division I of the post graduate part of the Mathematical Tripos in the following year He was immediately elected to a fellowship and was responsible for the mathematical teaching in Pembroke until the time of his death He had also served as assistant tutor and prætector of the college He died very suddenly and unexpectedly on May 19

It was as a teacher rather than as an investigator that Birtwistle was known and as a teacher that he played a conspicuous part in Cambridge mathematics especially during the last ten years In certain respects his position was unique for he was a link between the older theoretical physics and the new Since the War while continuing to lecture on classical mechanics electrodynamics and hydrodynamics his interest in more recent developments always strong rapidly increased He began to lecture on the older quantum theory on thermodynamics (then just introduced into the schedule of elementary teaching) and finally on modern quantum mechanics Each of these lecture courses ultimately grew into a book

As a lecturer Birtwistle was admirably clear and easy to follow He set, in fact, a standard of exposition which made it very difficult for anyone to attract students to any duplicate course His books are like his lectures—admirable expositions of those sections of the subject with which he deals, written in lecture room style He seldom attempts to go deeply into difficult points or to present the subject as a single logical whole His aim is the lecturer s aim—to interest the student in the subject, especially in its more outstanding or exciting parts, and lead him on to other more systematic or abstruse expositions

In all his lectures and in all three books, Birtwistle was successful in this aim, though naturally in varying degrees Perhaps the least successful of his books was the last on modern quantum mechanics Here owing to the novelty of the subject and the absence (when Birtwistle wrote) of other more systematic expositions (or indeed of any other exposition) the weakness of his deliberate method becomes more obvious The book gives rather the impression of a collection of interesting isolated sketches It stimulates the reader to ask for more but to what other author is he to turn? With the coming of other books the weakness is already less felt and Birtwistle s book is gaining in value as a stimulating introduction The staff of the Mathematical Faculty of Cambridge mourn the untimely loss of a valued friend and colleague

Dr W Martin

DR WILLIAM MARTIN who died on May 24 was known to a very wide circle as an antiquary whose knowledge and insight enabled him to see almost everywhere in London vestiges of the life and activities of former times but to many others he was known as an authoritative exponent of patent law and he was an occasional contributor to our columns upon this subject

Dr Martin s antiquarian bent led him to treat patent law historically but he was none the less alive to the conceptions which govern modern practice in this sphere In his lectures and publications notably his articles in the *Law Quarterly Review* he worked out with great originality a systematic key to the immense body of decided cases with which he seemed to be familiar in every part The law of treasure trove also attracted him and in it he saw contrary to the opinions of some antiquaries means which could be utilised for the advantage of archæology as a check on the surreptitious disappearance into private collections of finds of general interest

As an antiquary Dr Martin was insistent on a strict separation of ascertained fact from the accretions of sentiment and fancy which too often obscure instead of illuminating the past Nowhere was he more impatient of any looseness than in his

treatment of Shakspeniana He was an acknowledged authority on Shakspeare, and was proud of the part he took as president of the Shakspeare Reading Society in placing in Park Street, near Bankside, the handsome bronze memorial which now marks the site of the 'Globe'

Dr Martin was a graceful writer, clear and entertaining as a lecturer, and an ideal guide, with a very practical gift for organising which enabled him to carry through his arrangements strictly to time Perhaps he found his greatest happiness in conducting parties through almost forgotten alleys and byeways of London which he loved, and filling them from his stores of knowledge with pictures of the life of other days Many are those who have enjoyed afternoons spent with him on these rambles who will still find pleasure in the remembrance of his easy discourse and the charm of his personality He was keenly interested in many aspects of natural history, as well as being an authority upon archæological subjects and he served as president of the South Eastern Union of Scientific Societies It was particularly appropriate that Dr Martin should be elected the first president of the Gilbert White Fellowship, the object of which is "To continue the work of Gilbert White in the study of natural history and antiquities" He took an active part in the meetings and excursions of this Fellowship within a few days of the illness which resulted in his regretted death

---

WE regret to announce the following deaths

Prof Thomas W Cave, vice principal of the South Eastern Agricultural College, Wye, and for twenty seven years head of the Veterinary Department of the College, on April 25, aged seventy years

Mr A H Cheatle, C B E, the distinguished aural surgeon, who presented to the Royal College of Surgeons his valuable collection of preparations illustrating the anatomy of the mastoid region, on May 11, aged sixty two years

Prof Peter Gillespie, professor of civil engineering, University of Toronto at fifty six years of age

Commendatore Rodolfo Lanciani, K C V O, Senator of the Kingdom of Italy and formerly professor of Roman topography in the University of Rome, on May 21, aged eighty three years

Dr James Moir, a past president of the Chemical, Metallurgical and Mining Society of South Africa and of the Chemical Section of the South African Association for the Advancement of Science, on Mar 31

Mr O A Reade, pharmaceutical chemist, president of the Lowestoft and District Literary and Scientific Association, and author of a flora of the Bermudas, on April 14

News and Views

THE King's Birthday honours list includes the names of the following scientific workers and others associated with scientific activities *Baron* Sir Edward Allen Brotherton, chemical manufacturer *Privy Councillor* Lord Dawson of Penn, Physician in Ordinary to the King *Baronets* Sir E F Buzzard, Physician Extraordinary to the King, Sir Hugh Mallinson Rigby, Sergeant Surgeon to the King *Knights* Prof H C H Carpenter, professor of metallurgy in the Royal School of Mines, Imperial College of Science and Technology, Mr J J Ralph Jackson, Chief Veterinary Officer, Ministry of Agriculture and Fisheries, Mr W S Jarratt, Comptroller General of the Patent Office, Prof W C MacKenzie, Director, and professor of comparative anatomy, National Museum of Australian Zoology, Dr Peter Chalmers Mitchell, Secretary of the Zoological Society of London, Prof C V Raman, Palit professor of physics in the University of Calcutta, Brigadier E A Tandy, Surveyor General of India (retired), Dr R S Woods, Honorary Physician and Honorary Surgeon, London Hospital *K C B* Sir F S Hewett, Surgeon Apothecary to the King *C B* Major General H P W Barrow, Director of Hygiene, War Office *C S I* Mr James Herman Field, late Director General of Observatories, India *G C M G* Sir John Cadman, emeritus professor of mining, University of Birmingham *C M G* Dr L Cockayne, in respect of honorary scientific services to the Government of the Dominion of New Zealand, Mr O F H Atkey, Director of the Sudan Medical Service *G C V O* Sir Humphry Rolleston, Physician-in-Ordinary to the King *C V O* Dr L E H Whitby, bacteriologist *M V O* Prof E C Dodds, professor of bio chemistry at Middlesex Hospital *C I S O* Mr W A Baker, lately Surveyor General, Jamaica, Mr J F Halpin, Superintending Chemist, Government Chemist's Department *G B E* Prof Dame Helen Gwynne Vaughan, professor of botany in the University of London, Sir Arthur McDougall Duckham, Director General of Aircraft Production *K B E* Major General T H Symons, Honorary Surgeon to the King, Director General, Indian Medical Service *C B E* Mr P N H Jones, Director of Public Works, Bermuda, Lieut Col F J McCall, Director of Veterinary Services, Tanganyika Territory, Capt R S Rattray, for services as Government Anthropologist in the Gold Coast and to aviation in West Africa, Col A H Safford, Assistant Director of Medical Services, Baluchistan District, India, Mr Nicholas White, Chief Engineer, and Secretary to the Government of the Punjab, Irrigation Branch *O B E* Mr H Brown, Principal Officer, Plant and Animal Products Department, Imperial Institute, Major D G Cheyne, Deputy Assistant Director of Hygiene, China Command, Dr F Dixey, Director of the Geological Survey, Nyasaland Protectorate, Major J N Duggan, professor of ophthalmic medicine and surgery, Grant Medical College, Bombay, Mr J C F Fryer, Director, Ministry of Agriculture and Fisheries Pathological Laboratory, Harpenden, Lieut Col F J M Stratton, professor of astrophysics in the University of Cambridge, Mr G Stuart, Assistant Director, Laboratories, Department of Health, Palestine *M B E* Mr E W Davy, Assistant Director of Agriculture, Nyasaland Protectorate

THE Lords Commissioners of H M Treasury have appointed a committee to inquire into matters affecting the functions and staff of certain Research and Experimental Establishments of Government Departments, with the following terms of reference To examine the functions and organisation of the undermentioned Establishments in the Government Service and to report on the method of recruitment and conditions of service of the civilian scientific and technical officers employed therein (*a*) The Research and Experimental Establishments under the Admiralty, War Office Air Ministry, and Department of Scientific and Industrial Research (*b*) the Department of the Government Chemist and the Establishments under the Admiralty and War Office concerned with chemical analyses, and (*c*) the Meteorological Office

THE chairman of the committee is Prof H C H Carpenter, professor of metallurgy, Royal School of Mines, and the members are Sir W J Larke, the director of the National Federation of Iron and Steel Manufacturers, Sir Robert Robertson, government chemist Mr F M Morris, the assistant secretary at the Treasury in charge of staff questions affecting the Defence Departments Mr R J G C Paterson, one of the directors of finance at the War Office Dr F F Smith, director of scientific research, Admiralty, Mr H T Tizard secretary of the Department of Scientific and Industrial Research, and Mr H F Wimperis, director of scientific research, Air Ministry The secretary is Mr H Brittain, a principal at the Treasury

As was indicated in our leading article of May 11, the impending appointment of an inquiry into the organisation and lay out of the research and experimental branches of the Civil Service was used in April last by the representatives of the Government on the National Whitley Council for the Civil Service as a reason for refusing a Joint Committee which the Staff Side at the instance of the Institution of Professional Civil Servants, had proposed It was understood that the official committee then foreshadowed would cover the whole of the research and experimental activities of government departments and would deal mainly, if not exclusively, with the widest questions of structure and organisation Under the terms of reference now announced, however, the committee's sphere of action does not include the Museums, the Observatories, or the Research Services of the Ministry of Agriculture and Fisheries, and its authority to deal with matters of high policy is apparently confined to examination We are also a little mystified by the relationship of this new committee to the Research Co ordination Sub Committee of the Committee of Civil Research which was appointed in 1926 under the chairmanship of Mr W G A Ormsby Gore, and which presumably is continuing to function, since the report which it issued last year was purely descriptive in character We understand that the Institution of Professional Civil Servants, which represents the staffs to be considered by the committee of inquiry, has been invited to submit evidence, but has not yet decided its policy

EDUARD SUESS the most illustrious member of the great school of geology in Vienna, was born in London on Aug 20, 1831, and the Geological Society has placed a memorial tablet on the house, 4 Duncan Terrace Islington The tablet was unveiled on May 28 by his Excellency the Austrian Minister, Baron G Frankenstein The president of the Geological Society, Prof J W Gregory, remarked that Suess came of a family that was settled in South Saxony by 1524 His father was destined for the Church in which many of his ancestors had served, but he entered the wool business and lived for a time in London He removed to Vienna, where Eduard Suess graduated at the University served on the staff of the Royal Museum and was appointed professor at the University in 1857 Suess applied his geological knowledge to the provision of a better water supply for Vienna and thereby effected a great improvement in the health of the city, which became a pioneer in the improvement of municipal water supplies Suess's world wide scientific reputation depends on his contributions to geology and physical geography His views were most fully published in his 'Face of the Earth", they were so original and unorthodox that he was for a while regarded as a visionary, and his writings set aside as 'geo poesy'

SUESS's main principles have been generally accepted and have had a fundamental influence on modern ideas of the internal structure of the earth and its geographical evolution Before his work it was generally believed that changes in the distribution of the sea and land were due to irregular local oscillations of the crust Suess held that they were mainly regular and world wide in range, and due to changes in the form of the earth that cause a general advance of the sea at one time and retreat at another The origin of mountain chains he attributed to the crust being folded by pressure in one direction forming waves which advance until they are stopped by older rigid masses of land, as waves of the sea are kept back by the projecting forelands along a coast Suess ranks as the greatest original force in the geological philosophy of his time, as well as being remarkable, for his influence as a far seeing educationist and municipal reformer, statesman, and economist The Austrian Minister expressed his pleasure at this recognition of the work of the great Viennese geologist The Rt Hon Sir Maurice de Bunsen, on behalf of the Royal Geographical Society, expressed appreciation of Suess's work Dr F A Bather, representing the Royal Society, referred to the scientific imagination with which Suess handled his material Alderman Harper, the Mayor of Islington, promised that the local authorities would see to the safety of this memorial to one of the illustrious sons of Islington Sir Arthur Smith Woodward and Prof W J Sollas, in moving a vote of thanks to the Austrian Minister, referred to Suess's nobility of character and literary distinction

A PARTICULARLY interesting account is given in the *Engineer* of May 31, of the replica of the famous locomotive *Rocket*, which won the competition at

Rainhill on the Liverpool and Manchester Railway in October 1829, and at the same time established once and for all the suitability of the steam locomotive for railway work The original *Rocket*, or what remains of it, stands in the Science Museum, South Kensington, but the replica has been made for Mr Henry Ford for his museum at Detroit The task of building the new *Rocket* was given to Messrs Robert Stephenson & Co, Ltd, Darlington, the successors of the old Stephenson firm at Newcastle, and immense pains have been taken to follow as closely as possible the original plans As is well known, the original *Rocket* was altered very considerably and to day many parts are missing The design of the fire box—one of its most important features—has long been a matter for inquiry and discussion but apparently the experts are now fairly well agreed as to the details, and in the replica Mr Ford possesses what is undoubtedly the most complete piece of engine reconstruction ever carried out Though there are various memorials to George and Robert Stephenson and to Henry Booth, who were jointly responsible for the building of the *Rocket*, on June 8 we shall possess another memorial to George Stephenson, for on that day the Lord Mayor of Newcastle upon Tyne will unveil a tablet on the cottage at Wylam, Northumberland, where he was born The tablet has been erected through the joint efforts of the North East Coast Institution of Engineers and Shipbuilders and the Institution of Mechanical Engineers

MR E B FORD, of the Department of Zoology, University of Oxford, delivered a lecture before the Eugenics Society in the rooms of the Royal Society on May 29, on "Recent Work on the Physiology of Genetics and its Bearing on Human Problems" Mr Ford stated that the physiology of genetics has only been studied in comparatively recent years Indeed, it could scarcely have been investigated until a considerable body of evidence respecting the mechanism of inheritance had been built up Such evidence has now been obtained, and has resulted in an accurate knowledge of the behaviour of genetic factors and of the characters for which they are responsible, but the developmental processes by which these characters are produced are still for the most part obscure Prof R Goldschmidt in Germany has, however, thrown some light on this part of the problem He was led to postulate factors controlling the *rate* of production of sex differentiating substances in his work on sex determination, and later in other characters, in moths However, these are animals which differentiate by means of sudden metamorphoses For this reason they are unsuitable for an investigation of developmental processes This difficulty has to some extent been overcome in Great Britain by the study of a Crustacean which grows and develops throughout life By this means it has been possible to examine in detail a number of factors affecting the rate and time of onset of processes in the body, and their interaction with each other and with the environment It is probable that factors of this type are of great importance in the mammals In man they should be of particular interest, since so many of the differences which separate the human species from the apes are qualitative, and depend upon rates of development and the time at which certain processes begin We have here an indication of how such differences are inherited and controlled

THE Zoological Society of Scotland has entered upon a new and important stage of its steady development The large area of ground, formerly a golf course, which rises to the ridge of Corstorphine Hill, has been taken over, a road has been made traversing the new ground, large grass paddocks have been partitioned off, and a series of enclosures in the live rock has been created for beasts of prey at a cost of some £3500 Great improvements also continue to be made, we learn from the sixteenth Annual Report, in the older part of the Park Unsightly cages have been replaced by rock dens, and an extensive monkey house, designed on modern lines and now in course of erection, promises to be as successful as the recently built houses for tropical birds and reptiles The application of a device for the circulation and filtration of water has enabled the director secretary to add a number of salt water tanks to the Aquarium, much to its gain in attractiveness, and at a cost very much less than that of the original proposal for storage tanks During the year 86,000 visitors entered the Park, and the accounts show a record surplus on the year of more than £4700

THE teaching of Nature study in schools has been a problem bristling with difficulties, and to these difficulties is largely due the predominant place in school teaching taken by the more concrete sciences of chemistry and physics Part of the trouble is due to the impossibility of finding teachers with the necessary outlook and training, and this, we are inclined to think, may be traced to the tendency of the training colleges to model the biological syllabus too closely upon the botanical and zoological courses in the Universities That is to say, too much stress has been laid upon the structure and systematics of plants and animals and too little upon life activities It is, therefore, with unusual pleasure that we welcome a course of Nature study, which in the hands of an intelligent and sympathetic teacher should bring to the class room the real feeling of the progression of living things The course is outlined week by week in *The Schoolmistress*, under the title "In England—Now!" by Mrs Maribel Edwin, the daughter of Prof J Arthur Thomson The general scheme of the series is to follow natural history the year round in Britain, and this is accomplished by striking in the first week of each month the keynote of the month, and in the succeeding weeks, by analysing the month's activities in greater detail The treatment exhibits insight and imagination, and the wall diagram, on which pictures of the creatures and plants referred to may be hung in their appropriate environment month by month, strikes a practical note which must appeal to teacher and pupil alike

THE fifth meeting of the Wool Breeding Council, appointed jointly by the Secretary of State for Scotland and the Minister of Agriculture and Fisheries

to advise the Departments of Agriculture for England and Wales and Scotland on questions relating to the improvement and utilisation of wool grown in Great Britain, was held at the Animal Breeding Research Department University of Edinburgh, on May 23 Sir Robert Greig, chairman of the Council, presided Short statements on research work in progress were submitted to the Council In co operation with the University College of North Wales, Bangor, large scale breeding experiments have been conducted in order to determine the mode of inheritance of the birth coat of lambs and the relationship between the type of birth coat and kemp in the subsequent fleece At the Animal Breeding Research Department, University of Edinburgh, the work includes a critical repetition of the grafting experiments carried out by Dr Voronoff a study of the rôle of the pituitary gland in producing early maturity, and an investigation into the possibility of securing the moulting of kemp by the use of thyroxin

DR E N DA C ANDRADE described "The Air Pump Past and Present" in a discourse delivered by him at The Royal Institution on May 31 The obtaining of a vacuum is an essential step in the majority of modern physical experiments, and in many of the products of the modern electrical industry, such as the electric lamp, the thermionic valve, and the X ray tube With modern methods a pressure of a ten thousand millionth of an atmosphere can be attained, which means only a few hundred million molecules per cubic centimetre During the past sixteen years new principles of obtaining high vacua have been applied which have proved of the utmost importance for the laboratory and electrical work shop At very low pressure the free path between the collision which a molecule makes with others is long, and the new pumps do not come into action until this state has been reached, and so work in conjunction with a preliminary pump which reduces the pressure sufficiently In one type a cylinder provided with special grooves rotates very rapidly, and actually throws the molecules forward as sparks are thrown by a grindstone this type of pump is usually called a molecular pump, and is very efficient, but demands great care in construction In another type, which might with equal justice be called a molecular pump, since it is based on a consideration of molecular properties, a jet of vapour entrains the molecules which diffuse into it, and the pump is therefore often called a diffusion pump The vapour itself has to be condensed, so the pumps are also called condensation pumps Hitherto mercury vapour has generally been used for these pumps, on account of the non volatile nature of the liquid at ordinary temperatures, but within the last year oils have been produced which can take its place, and within the last month or two another liquid still has been utilised

THE first David Ferrier lecture of the Royal Society will be delivered on June 20 by Sir Charles Sherrington, upon the subject of "Some Functional Problems attaching to Convergence"

DR H S H WARDLAW, of the Department of Physiology of the University of Sydney, has been elected president of the Linnean Society of New South Wales for the current session

PROF RAYMOND A DART professor of anatomy in the University of the Witwatersrand, Johannesburg, has been elected a corresponding member of the Italian Society of Anthropology, Ethnology, and Comparative Psychology The society was founded in 1871 and the number of corresponding members is limited to ninety

FURTHER information is now available with regard to the large earthquake which was recorded at Kew Observatory and other seismological stations on May 26 In a message which was broadcast on May 27, in code, from Arlington the United States Coast and Geodetic Survey gives the position of the epicentre as in Lat 56° N Long 137° W, that is under the Pacific Ocean, about 100 miles from Sitka, Alaska The time was 22 hr 40 min G M T, which is 14 hr 40 min Pacific Coast time

BY kind permission of the director of the Rothamsted Experimental Station, Harpenden a summer meeting of the Royal Meteorological Society will be held there on Wednesday afternoon, June 12 Fellows will make a general tour of inspection of the various departments, and will visit the classical field plots and the meteorological station, where a number of recording instruments are maintained

AT the general meeting of the Imperial Academy of Japan, held on April 12, Sir Alfred Ewing was elected a foreign member The president, in announcing this election, stated that the Academy most highly appreciated Sir Alfred's numerous and important contributions to science and gratefully remembered his untiring efforts in promoting in Japan the spirit of studying science for its own sake when scientific study was just beginning to be pursued in that country half a century ago

THE New York correspondent of the *Times* announces that Prof Henry Fairfield Osborne president of the American Museum of Natural History has secured from the Muller heirs in Sao Paulo Brazil, the originals of an entire series of letters from Charles Darwin to the great German naturalist, Dr Fritz Muller, with the view of sending them to be added to the memorial collection at Down House

APPLICATIONS are invited for the following appointments, on or before the dates mentioned A science teacher for day and evening work at the Walker Technical College, Wellington Shropshire—The Principal, Walker Technical College, Hartshill, Wellington Shropshire (June 11) A lecturer in engineering at the Wigan and District Mining and Technical College—The Principal, Mining and Technical College, Wigan (June 12) A full time assistant lecturer in pharmaceutical subjects, and a full time lecturer in electrical engineering at the Leicester College of Technology—The Registrar, College of Technology, Leicester (June 19) An

adviser in agricultural chemistry in the University of Manchester—The Registrar, The University, Manchester (June 20) A lecturer in physics in the University of Durham (Durham Division)—The Head of the Department of Science, University of Durham, South Road, Durham (June 22) A lecturer in mechanical engineering at Armstrong College—The Registrar, Armstrong College, Newcastle upon Tyne (June 22) An assistant inspector under the Ministry of Agriculture and Fisheries for work in connexion with agricultural and horticultural education and research—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place S W 1 (June 24) Two assistant superintendents under the Geological Survey of India—The Secretary to the High Commissioner for India General Department, 42 Grosvenor Gardens, S W 1 (June 24) A director of the Bureau of Economic Research of the Commonwealth of Australia—The Official Secretary, Commonwealth of Australia, Australia House, Strand W C 2 (July 1) A professor of Indian history and archæology in the University of Madras — The Registrar, University of Madras, Triplicane P O Madras (August 19) An instructor in engraving and etching and an instructor in decorative composition and design in the new Higher School of Fine Arts Cairo—The Ministry of Education Cairo (Sept 30) A chemist under the Air Ministry, Kidbrooke, with up to date knowledge of analytical methods, organic and inorganic chemistry, with specialised knowledge of one of the following subjects (a) metallurgy, (b) petroleum technology, (c) non metallic aeronautical materials, i e lubricating oils, dopes, paints, etc , (d) textiles, also a chemist with analytical experience in organic and inorganic work, and, if possible, specialised knowledge of metallurgical chemistry or petroleum technology—The Secretary (I G), Air Ministry, W C 2 A supervisor for the scientific instrument testing department of W G Pye and Co - W G Pye and Co , Granta Works, Cambridge A laboratory steward for the bio chemical laboratory of University College London—The Secretary University College Gower Street, W C 1 A plant physiologist at the Welsh Plant Breeding Station, Aberystwyth — The Secretary, Welsh Plant Breeding Station, Agricultural Buildings Aberystwyth A laboratory assistant for the Health Department of the Government of Iraq—The Crown Agents for the Colonies, 4 Millbank S W 1 (quoting M/1546) A junior assistant at the Experimental Station, Porton—The Chief Superintendent, Chemical Warfare Research Department, War Office, 14 Grosvenor Gardens, S W 1

Our Astronomical Column

MATTER IN INTERSTELLAR SPACE —The existence of interstellar calcium, as evidenced by the detached [H] and [K] lines in stellar spectra, has for some time engaged the attention of Dr O Struve (see for example, NATURE vol 122, p 252) His latest researches, made in collaboration with Prof B P Gerasimović, and described in the *Astrophysical Journal*, vol 69, p 7, deal with the physical properties of calcium and other elements in interstellar regions Eddington's hypothesis of an interstellar substratum embodying the whole galactic system is regarded as the most satisfactory hypothesis at present, and the one most in accordance with both observational data and theoretical considerations This substratum consists of many elements in various states of ionisation, with an average density of the order of 10^{-26} The observed intensities of detached Ca^+ lines show a definite distance effect such as would be expected from a uniform distribution of Ca^+ with a density of about $3\ 6 \times 10^{-31}$ The substratum of interstellar matter appears to share the rotational motion of the stars round a distant central mass in galactic longitude 325°

THE SUNSPOT CYCLE AND THE CORONA —It is about half a century since it was first noticed that the form of the corona varies with the progress of the sunspot cycle Our knowledge on the subject has become more definite from the aid afforded by the long series of coronal photographs that is now available Recently, studies on the subject have been made by Profs H Ludendorff and S A Mitchell The latter contributes an article to *Popular Astronomy* for April, which discusses and amplifies Ludendorff's conclusions The ellipticity of the corona near the sun's limb is denoted by a, that at a distance of one radius from the limb by $a + b$, a varies very little with the sunspot cycle, its mean value being 0 04, b is zero at maximum sunspot activity and about 0 26 near minimum activity it appears, however, to reach its maximum a year or two before sunspot minimum Mitchell notes that the coronal spectrum appears also to change its type thus the line at λ6374 in the red, which is not often observed, was well seen both in 1914 and in 1925 these being at the same phase of the cycle It is suggested that the Wolf numbers are a better guide to the type of corona than the phase of the sunspot cycle, it is also noted that the corona of 1918 was abnormal, it occurred a year after sunspot maximum, and had most of the features of maximum type, but there were also the strong polar brushes associated with minimum type

OCCULTATIONS OF STARS BY VENUS —*Acta Astronomica*, series A, vol 2, contains a discussion by J Witkowski of the occultations of three stars by Venus That of the star BD - 0° 2554, mag 7, was observed at Teramo on Nov 9, 1895 This had not been predicted, and was observed by chance Prof T Banachiewicz predicted that of the 4th magnitude star η Geminorum on July 26, 1910, it was observed at seven observatories Dr L J Comrie predicted that of BD + 18° 1499, mag 7 4, on Aug 22, 1924 Both phases were observed at Neu Babelsberg, and the reappearance at Bergedorf

From discussion of these phenomena Mr Witkowski finds a correction of $-0\ 58'' \pm 0\ 23''$ to Hartwig's value of the diameter at distance 1, which is 17 552" This is in fair accord with Auwers's value 16 820" derived from the transits of Venus in 1874 and 1882 He finds corrections to the *Nautical Almanac* positions of Venus which agree fairly well with those found with the Greenwich Transit Circle The observations lead him to suspect some refraction of the stars due to the atmosphere of Venus

Research Items

Secret Societies and the Bull Roarer.—Mr. Edwin M. Loeb, in a study of tribal initiation and secret societies (*University of California Publications in American Archæology and Ethnology*, vol. 25, No. 3) makes a world-wide survey of the evidence and reviews the theories of previous writers on these features of social organisation. The tribal initiations fall into two classes, those which are exoteric, that is, those to which all members of the tribe are subject but in which no attempt is made to preserve secrecy as to details, and the esoteric, of which the detailed rites are kept secret. It is out of these latter that the secret society grows, the distinctive feature being that they are exclusive. Secret societies are not as in the opinion of certain writers to be connected with the matriarchate, and though totemism and the sib system attach themselves to secret societies in certain areas, tribal customs and secret societies belong to an older stage of social organisation than either. It is noted that while boys' initiations are tribal, that of girls is a family matter. Both boys' and girls' initiations are common among backward peoples. They occur among Negroids and Australians and regionally in the New World, but are lacking among other Mongoloids, and also among Caucasians with the doubtful exception of the 'mysteries' of ancient Greece. From the distribution it is inferred that these traits are of archaic, possibly palæolithic, origin, and not a matter of recent diffusion. As regards the bull roarer, earlier theories are to be regarded as untenable. It would be possible to regard it as of independent origin in different regions only if attention were confined to its use as a toy or for purposes of magic. In connexion with initiation and secret societies, it is always associated with a form of tribal marking, a death and resurrection ceremony, and an impersonation of ghosts and spirits. It is tabooed to women and is invariably represented as the voice of spirits; but when found outside the area of initiation rites and secret societies it is neither. As there is no psychological principle which debars women from the sight of the instrument in Oceania, Africa, and the New World, it cannot be regarded as due to an independent origin and it must be inferred that it has been diffused from a common centre.

Antagonism between Tuberculosis and Cancer.—From a statistical survey of the incidence of cancer (carcinoma and sarcoma) among tuberculous and non-tuberculous individuals, Prof. Raymond Pearl concludes that there is a marked and definite incompatibility or antagonism between the two diseases (*Amer. Jour. of Hyg.*, **9**, 97; 1929). Active tuberculous lesions were found at autopsy in only 6·6 per cent. of 816 persons having malignant growths, and in 16·3 per cent. of 816 persons without malignant tumours, but of the same race, sex, and age as the former group. In 886 persons of both sexes and races compared, who were the subjects of active tuberculous lesions, there were but 11 cases of malignant tumours, or 1·2 per cent. of the total number, but in a similar group of 886 persons with no recorded tuberculous lesions there were 82 cases of malignant tumours, or 9·3 per cent. It is only when *active* tuberculous lesions are present that the antagonism seems to exist, for *healed* tuberculous lesions occurred with equal frequency in the malignancy and control groups.

Breeding and Migrations of the Elephant Seal.—The two species of seals which we have had opportunities of studying in British waters have distinct but well defined and compact breeding periods. It is curious that the elephant seal (*Macrorhinus leoninus*) should have so diffuse a breeding period, but the evidences collected by Mr. F. McLennan Davidson leave the matter in no doubt (*Proc. Calif. Acad. Sci.*, vol. 18, April 1929). On Juan Fernandez young seals have been found from June 10 to Sept. 19; on Guadaloupe Island on Oct. 9, Mar. 5, and May 8; and on the Lower Californian Islands from Nov. 1 to Feb. 1. That is to say, young of the elephant seal have been found in practically every month of the year, although a certain allowance must be made for the fact that the young seals recorded were not in every case new born. Rothschild considered that a regular migration of the adult seals took place to the Chilian coast and the islands near (Juan Fernandez, etc.), but various facts suggest that such a migration is improbable. Elephant seals have been found in the Antarctic pack ice in January, pointing to a movement away from, rather than across, the equator; and the evidence of a prolonged breeding season as well as the presence of a considerable herd of elephant seals in North American waters during all seasons also tell against the possibility of a migration to Juan Fernandez.

The European Starling in North America.—Several attempts were made to establish the European starling in the United States before a successful introduction was made in 1890 at New York City. By 1896 it had become firmly established in this area and since that time its spread has been so rapid and its hold upon the country so secure that it must now be regarded as a naturalised member of the North American fauna. Within twenty years it had become one of the most abundant birds in the region about New York City and of local occurrence from Maine to Maryland. In another dozen years it had occurred in every State from the Atlantic to the Mississippi and from the Ottawa and St. Lawrence Rivers in Canada to the Gulf of Mexico, with outlying records in Nova Scotia, Iowa, Missouri, Kansas and Texas. The conquest has been viewed with some concern. It can scarcely be doubted that so great numbers of a new comer must affect adversely the numbers of native birds, and it tends to drive some away from the vicinity of houses by ousting them from nesting sites. On the whole the starling's feeding habits are probably beneficial, but the greatest danger arises from its custom of gathering in enormous flocks after the breeding season, so that harm is caused by over-concentration in crop areas or from the insanitary habits of the birds (May Thacher Cooke, in *U.S. Dept. Agr. Circular*, No. 40). These are complaints which have been proved against the birds in Great Britain.

Malaria Mosquitoes of South Africa.—In Publications of the South African Institute for Medical Research, vol. 4, 1929, pp. 83-170, Messrs. Alexander Ingram and Botha de Meillon contribute the second part of a "Mosquito Survey of certain Parts of South Africa with Special Reference to the Carriers of Malaria and their Control." It deals with survey work carried out in the eastern and northern Transvaal during a portion of the malarial season, which is considered to last from January to May. The two recognised carriers of malaria in South Africa—*Anopheles funestus* and *A. gambiæ*—differ essentially in their breeding habits. *A. funestus* prefers the edges of slowly running streams, which are in deep shadow, for oviposition, while *A. gambiæ* resorts to shallow pools or puddles exposed to sunlight. *A. gambiæ* shows a decided seasonal prevalence, whereas *A.*

funestus does not appear to exhibit this feature It is because *A gambiæ* is much the more numerous of the two species during the malaria season that the authors regard it as the main malaria carrier They consider that concentration upon the reduction in numbers of this insect is more likely to bring about a diminution of malaria than an indiscriminate attempt against Anophelines in general The paper includes detailed descriptions of the larvæ and pupæ of certain South African mosquitoes not hitherto described, and these descriptions are accompanied by 28 illustrations

LUMINOUS SQUIDS —M Ishikawa (*Proc Imp Acad Sci*, Tokyo, January 1929) describes *Abralia japonica*, a new species of luminous squid from the Sea of Japan The total length of the squid is 116 mm Numerous minute luminous organs, as dark bluish dots with a paler opaque lens in the centre, are distributed over the ventral surface of the mantle, head, funnel, and the ventral and third arms On the ventral periphery of the eye are five circular luminous organs, brownish orange in colour, visible through the outer integument which covers the eye T Kishitani (*Proc Imp Acad Sci*, Tokyo, December 1928) gives a preliminary account of the pair of luminous organs of *Loligo edulis*, which are sunk in the ink sac, one on each side of the rectum The author has found a coccobacillus in the tubules of the gland tissue which forms the luminous part of the organ, and records the cultural characters of the organism and its action on sugars

RUST RESISTANCE OF WHEAT —The resistance of wheat to leaf rust, *Puccinia triticina*, has generally been regarded as a definite, heritable, and relatively stable character However, several workers have recently demonstrated that differences in external conditions, such as the variation between growth in the field and in the greenhouse, may have an important bearing on the crop's resistance to this disease C O Johnston and L E Melchers have now shown (*Journal of Agricultural Research*, 38, p 147) that under greenhouse conditions the age of the wheat plant is frequently an all important factor in determining whether or not infection shall occur A number of different wheat varieties were tested by inoculations with rust at three distinct stages of growth, after one month, as the period of winter dormancy was just ended and also when the head had fully emerged Whereas some varieties changed but little in their reaction to the disease, remaining susceptible or resistant throughout their growth period, others showed a definite alteration in their reaction according to their age Resistance, however, invariably increased towards heading time From the plant breeder's point of view, this affords a ready means of testing new varieties, since if resistant in the seedling condition, resistance is assured at all later stages of growth Thus new hybrids which appear promising but are really worthless on account of their susceptibility to rust may be discarded by means of this simple test before time has been wasted upon them Wheats showing an increase in resistance with age also showed a variation in the degree of susceptibility of their leaves The higher the leaf on the stem the greater its resistance to rust, from which the authors suggest that the change in the plant's reaction to the disease is probably correlated with some chemical or physiological change in the leaf

GREEN ALGÆ OF THE SEA OF JAPAN —The Pacific Scientific Fishery Research Station in Vladivostok just published in its *Bulletins* (vol 2, part 2, 1928) a paper by E S Sinova on the Chlorophyceæ of the Sea of Japan The work is based on numerous collections made by many Russian expeditions since 1870 and preserved in the Botanical Gardens and the University of Petrograd as well as on the personal observations by the author in 1926 The sea bottom is mainly rocky, and the rocks are covered by a continuous carpet of seaweeds The salinity of the water near the mouth of rivers is 32 33 per mille, and the principal genera of algæ present there are *Scytosiphon*, *Punctaria*, *Ulva*, and *Laurencia* All the rocky grounds in the northern part of the Bay of Peter the Great are overgrown by the 'sea cabbage', *Laminaria japonica*, which reaches gigantic dimensions and covers very large areas of the bottom This seaweed forms a basis of a very important industry, since more than 15 million pounds of the dry weed are exported annually to China for food and for technical purposes *Sargassum* and *Cystophyllum* occupy large stretches of the bottom, while *Zostera japonica*, *Z marina*, and *Z pacifica* form such dense colonies that navigation is made difficult in places Three new forms of *Laminaria japonica* are described and *Ceramium subverticillatum* (Grun) Web, described from New Caledonia, is recorded for the Sea of Japan for the first time A parasitic seaweed, *Streblonema* (*Ectocarpus*) *parasiticus* (Sauv), occurs abundantly on *Ceramium cubrum* (Huds) Ag, *Gracilaria confervoides* (L) Grev, and on *Camphœlophora hypneoides* J G Ag

DATA ON TERRESTRIAL MAGNETISM —The March issue of *Terrestrial Magnetism* contains a wide variety of articles on theoretical and observational aspects of the subject, the diamagnetic theory of the daily magnetic variation is discussed by its author, Ross Gunn, and by S Chapman, and the density and other conditions in the outer atmosphere are described in an interesting speculative paper by H B Maris Hafsted and Tuve report observations, by means of wireless echoes, of abnormal changes of height of the reflecting ionised layer in the upper atmosphere during magnetic storms There is also a list of preliminary values of the ocean magnetic determinations made by the non magnetic ship *Carnegie* on its voyage from Balboa to Easter Island and Callao, October 1928 to January 1929, the promptness of publication of such observations is a matter on which the Department of Terrestrial Magnetism of the Carnegie Institution of Washington can feel just pride

LUMINOSITY OF THE NIGHT SKY —The Australian Commonwealth Solar Observatory has issued its first publication (*Memoirs*, vol 1, No 1), entitled "The Luminosity of the Night Sky" It describes the observations made with a Rayleigh night sky photometer during 1926 and 1927, first at Canberra, and later at Mount Stromlo, about seven miles away The green auroral light has high values in March and April, whereas in England the maximum is in October, in each case there is a suggestion of a second maximum near the other equinox Dr Duffield, the director, found that the blue part of the spectrum was likewise unusually intense near the equinoxes, and attributes this to nitrogen bands such as occur in the spectrum of polar auroræ, themselves specially frequent at these seasons hence he supposes that the equinoctial maxima of the green auroral light are due to polar auroræ At other times of the year, though there is an excess of green auroral light over that to be found in diffuse light from the sun or moon, there is no evidence of excess blue radiation He therefore accepts Rayleigh's distinction between polar and non polar auroræ The period of observation, two years, is too short to indicate whether there are changes of the night sky light associated with the sunspot epoch, and it is greatly to be hoped that these southern observations will be continued for several years

Thermo electric Properties of Metal Crystals—The February issue of the *Proceedings of the American Academy of Arts and Sciences* contains an account of Prof P W Bridgman's investigations of the resistivities and thermo electric properties of rods of metal from a single crystal which he has carried out with aid from the Rumford Fund The rods 8 cm long and 0 3 cm diameter, are obtained by slow cooling from below upwards of a number of connected glass tubes inclined at different angles to the vertical, and filled with the molten metal The whole contents of the tubes are then parts of a single crystal The resistivities of rods of zinc, cadmium, antimony, tin, and bismuth, inclined at various angles to the crystalline axes, were found to follow Kelvin's law that they should be linear functions of the square of the cosine of the angle of inclination When each rod was soldered between copper leads and the junctions kept at different temperatures, the thermal electromotive forces were found to follow the same law, with deviations in the cases of tin and bismuth which are greater than the possible experimental error

Recombination Spectra—A neat experimental method for investigating the neutralisation of positive ions by free electrons has been described by Dr F L Mohler and C Boeckner in the March issue of the *Journal of Research* issued by the U S Bureau of Standards During the recombination, continuous spectra are emitted in the form of bands shaded to the violet, with their heads close to fundamental lines in the arc spectra of the resulting neutral atoms The distribution of intensity in the individual bands can be determined photometrically, and at the same time the concentrations of the ions and electrons and the average thermal energy of the latter, can be found by the probe wire method of Langmuir and Mott Smith, by combination of the electrical data and the optical data it is then possible to calculate the chance that a slow electron of specified speed shall fall into any one of the more important unoccupied orbits of the atom in question An outstanding feature of this work is that it confirms the somewhat surprising conclusion which had been arrived at from the study of the positive column of mercury arcs, that even under favourable conditions recombination in the gas phase is a relatively rare event The discharge tubes used by Dr Mohler were of a very simple type, being in fact almost identical with gas filled wireless valves containing helium or cæsium vapour, and operated in the 'blued' state

Single Crystals of Silver—Single crystals of various metals have been prepared in the form of rods or wires, and Hauser has obtained etch patterns, showing the crystallographic form, on spherical single crystals of copper and silver The first preparation of large single metallic crystals possessing the characteristic external form appears to be that carried out in the case of silver by Steacie and Toole and is described in the *Journal of the American Chemical Society* for April The metal is fused in the absence of air, cooled slowly and then kept at 940° for two days Dilute nitric acid attacks the faces of the single crystal thus obtained in a specific manner resulting in the formation of a prismatic crystal

Germanium Dichloride—The preparation of germanium dichloride, by passing the vapour of the tetrachloride, free from hydrochloric acid, over metallic germanium at about 430°, is described by Dennis and Hunter in the *Journal of the American Chemical Society* for April Germanium dichloride is a pale yellow solid which is instantly decomposed by moisture and is slowly acted upon by dry oxygen in accordance with the reaction $2GeCl_2 + O_2 = GeO_2 + GeCl_4$ It readily dissociates on heating, and hence cannot be purified by sublimation Germanium dichloride is unaffected by alcohol and chloroform but is hydrolysed by water, ammonium hydroxide solution converts it into an orange coloured substance

Apparent Influence of an Electric Field on the Boiling Point of Benzene—It has been shown by Baker that when an electric field is applied to benzene in a tube heated by an oil bath, the boiling point, as registered by a thermometer in the liquid appears to be considerably raised The same effect was later observed by Smits who showed that the vapour pressure remains unchanged and that if the heating is carried out directly with a flame the liquid boils at the normal temperature Smits attributed the phenomenon to superheating rendered possible by the removal of charged dust particles by the field In the *Journal of the Chemical Society* for April J W Smith describes experiments which show that the effect is very much reduced by vigorous agitation of the benzene, and when ebullition has commenced before the application of the electric field then the boiling point remains unaltered In all cases the vapour temperature has the normal value The explanation advanced by Smits appears therefore to be correct

Lanoline Rust Preventers—The Department of Scientific and Industrial Research has recently published an account (Engineering Research Special Report No 12 London H M Stationery Office) of an investigation of rust preventing mixtures carried out at the National Physical Laboratory Preservatives of a greasy nature are more satisfactory than hardening paints or varnishes, and the best results were obtained from lanoline either brushed on to a steel surface or deposited from solution Such coatings have very great adhesion to steel even at high temperatures Benzene is the best solvent to use for making up the lanoline solutions but solvent naphtha is more suitable for industrial use and is quite satisfactory Harder coatings can be obtained by the addition of paraffin wax or ceresin and if the solution is coloured, breaks in the film may readily be detected

Denicotinised Tobacco—An account of the so called 'denicotinised' tobacco is given by E M Bailey and others in the Report of the Connecticut Agricultural Experiment Station for 1927 (*Bulletin* 295) Many of these tobaccos are now on the market bearing the advertisement that the bulk of their nicotine has been removed, from which the consumer naturally concludes that the product has been rendered harmless Actual analyses, however, revealed the fact that on an average only one half to one third of the nicotine is removed in the re sweating process Further, since the percentage of nicotine varies enormously in different tobaccos, it is possible for a 'denicotinised' product to show as high a nicotine content as some other untreated tobaccos For example, the lowest percentage of nicotine found in a treated tobacco was 0 75, but certain types of Havana, Porto Rican, and Turkish tobaccos normally contain as little as 1 per cent From this it is clear that unrestricted indulgence of these tobaccos by people who suffer ill effects from nicotine is unwarranted The authors conclude with the suggestion that methods may be found which entirely remove the nicotine, though they raise the obvious query whether such refined tobacco would retain the qualities for which smoking is enjoyed

New Mining Department at Armstrong College, Newcastle-on-Tyne

ON May 14, H.R.H. the Prince of Wales opened the new Mining Department of Armstrong College. In his opening speech he said: "The industry is confronted with stern competition from overseas. It must be equipped to meet that competition, and I think it is generally agreed that it is to science that we must look in our distress. Science must show the way to an improvement in our methods, and scientific training must be available both for the leaders and the rank and file, so as to ensure that no single ounce of energy is lost in the tug of war against our competitors."

The demand that Armstrong College should intensify and enlarge its share of work of scientific research in the interests of the coalfields it mainly serves has recently become specific. The coal owners of Durham and Cumberland, the Federation of Iron and Steel Manufacturers, the Department of Scientific and Industrial Research and the coke and gas industries, have co-operated with the College in the formation of a committee to supervise and encourage the prosecution of researches bearing directly on their respective industries. This work is now well in hand; valuable reports have already been issued, and more may be confidently expected in the near future. Similar co-operation between the College and the Fuel Research Board has begun a physical and chemical survey of the coal seams in the northern coalfields is in progress, the chief purpose being to obtain an exact knowledge of the properties of those seams. This work is being carried out at present in temporary buildings, but it will shortly be transferred to the top floor of the new building.

The Department of Mining in Armstrong College has long and fine traditions behind it. It forms the oldest mining school in Great Britain, for it dates back in one form or another to the year 1837. Many of the foremost men in the mining industry to-day received their training in it. The present head of the Department is Prof. Granville Poole, who has designed the new building which now provides adequate facilities for the teaching of mining and the prosecution of research.

The erection of this building has been made possible only by generous grants from the Miners' Welfare Fund. The sum of £20,000 was subscribed by the Central Committee of the Fund and £10,000 from the Northumberland District Committee. Anonymous donors have contributed nearly £5000 to the equipment of the building and a further sum of £15,000 is required. The building will occupy a central position when the general scheme for the development of the College is completed. The architect is Mr. Dunbar Smith, of London, who was also the architect for the new College Library and for the National Museum of Wales, one of the noblest buildings erected in Great Britain within recent years.

Apart from the rooms set apart for research, the Department has several prominent features, for example, an exhibition hall containing plant and models of great educational value, and products from modern carbonising and hydrogenating plants, etc., also a specially equipped laboratory housing plant for the dressing of minerals.

The courses of the Department are arranged to meet the requirements of those who wish to specialise in any branch of mining, and the diploma and degrees obtainable are accepted by the Board for Mining Examinations in lieu of two years' practical experience in a mine.

Insect Nutrition and Metabolism

THE subject of nutrition and metabolism in insects is highly important, in that its adequate exploration is likely to provide fresh viewpoints for problems of insect control. At the same time its relation to such insect products as silk, lac, honey, and wax should not be overlooked. At the present time, knowledge of the metabolic processes of insects is limited to scattered experiments and observations usually confined to individual species, and of too inadequate a character to admit of reliable generalisations being made. The literature is very extensive and, for that reason, imparts the impression that a large amount of work has already been accomplished. A survey of any small branch in this field will, however, reveal how much of the available information is of a comparatively trivial or incomplete character, and what an infinitesimal amount of really fundamental knowledge has, so far, been gained.

In the *Transactions of the Entomological Society of London*, 1928, Part 2, Mr. B. P. Uvarov, senior assistant in the Imperial Bureau of Entomology, has brought together the results of all the work done on the subject of insect nutrition and metabolism. His memoir takes the form of an admirable introductory survey (65 pp.) of the range of problems involved, together with a bibliography of nearly six hundred titles. In the collation and examination of so large a mass of literature, the author has done a substantial service to entomology and laid the basis and provided a guide for future research.

If one selects, for example, the enzymes involved in the digestive processes of insects rather a surprising amount of data will be found available, but much of the material is the result of old, or of imperfect, methods of technique. There is also the fact that the part played by micro-organisms living in the digestive tract further complicates the subject. The need for clearly ascertaining which enzymes are produced by the insect and which by micro-organisms of symbiotic or other relationship is abundantly evident. With plant-sucking insects we have evidence that they are capable of converting starch into sugars, but we know nothing concerning their utilisation of the protein constituents of cell sap. Buchner went so far as to conclude that the symbiotic micro-organisms of aphids, coccids, etc., are able to utilise atmospheric nitrogen and so make up for a supposed deficiency in nitrogen absorbed by such insects from their plant hosts. It is, however, abundantly clear that there is no positive evidence indicating that sucking insects do not obtain and utilise all the nitrogen they need from the cell contents: we have to admit that the rôle of the symbionts is still unsettled.

Again, the problem of cellulose digestion in insects is very far from being settled in spite of the existence of tens of thousands of plant-feeding species. The presence of a cellulase has been found in very few insects and, for the vast majority of species, it would appear probable that, if cellulose is digested at all, it is by the intervention of micro-organisms, as has been so well demonstrated by Cleveland in the case

of termites We know surprisingly little concerning the nutritional requirements of blood sucking insects which are concerned with the transmission of the pathogenic agents of certain virulent diseases We need to know the length of time such insects can exist in the absence of a blood meal, the extent to which digestion of blood requires the interaction of micro organisms, the influence of different types of blood upon fecundity, and the extent to which the selection of one mammalian host in preference to another is a chemical or a biological problem

These few comments will serve to indicate the nature and importance of some of the problems involved It is to the credit of the Dietetics Subcommittee of the Civil Research Committee that it directed attention to the need for examination of the nutritional problem in insects Through the Empire Marketing Board it was able to arrange with the Imperial Bureau of Entomology to produce a collated bibliography of the whole subject, and Mr Uvarov's memoir was the result On the submission of the MS to the Civil Research Subcommittee, the latter body approached the council of the Entomological Society of London, through the Empire Marketing Board, with a view to its publication It must be added that the financial provision was made by the Empire Marketing Board, and that it affords yet another example of the breadth of view and wise foresight exercised by that Board in the furtherance of applied biological research

The inception, preparation, and publication of this memoir reflects the greatest credit on all concerned It may be added that Mr Uvarov's actual summaries of the papers listed in his bibliography have been deposited in the Reid Library of the Rowett Research Institute for Animal Nutrition, Aberdeen Arrangements have also been made for a set to be placed in the Science Library at South Kensington where they will likewise be available for consultation A limited number of copies of Mr Uvarov's memoir are available on application to the Secretary Committee of Civil Research 2 Whitehall Gardens, S W 1 A D IMMS

Annual Visitation of the Royal Observatory, Greenwich

AT the annual visitation of the Royal Observatory, Greenwich, by the Board of Visitors on Saturday, June 1, the Astronomer Royal presented his report, which describes the work of the observatory during the year ended on May 10 The observations with the transit circle numbered nearly nine thousand embracing the sun, moon, planets (of which special attention was paid to Vesta owing to its value for determining the equator point), fundamental stars and stars needed for comparison with Eros at the time of its near approach to the earth in 1930-31 The correction to the longitude of the moon as calculated from Brown's tables is +5 51" from the limb and +5 83" from the crater Mosting A The correction has been diminishing at the rate of a third of a second per annum since Brown's tables were introduced into the almanacs in 1923 The early observations of the sun and moon, from 1751 onwards, have been re reduced, it is found that the longitudes deduced from the declinations are more trustworthy in the early years than those from the right ascensions The results give support to the theory that there are variations in the earth's rate of rotation, they also indicate a secular acceleration of the sun's longitude, the amount of which is +0 78" in a century

Observations with the Cookson Zenith Telescope show that the variation of latitude in recent years has been abnormally small the large amplitude of seven years earlier has not been repeated

The 28 inch equatorial has been used for double star observation, 282 stars have been measured during the year, 44 of which are separated by less than half a second, a new working list of some 2000 pairs discovered by Dr Aitken has been prepared The old water clock used for driving this instrument, and its predecessor the Merz equatorial, since Airy's days has been superseded by an electric drive of the Gerrish type, which was on view for the first time at the visitation The Astronomer Royal gratefully acknowledges the help given in preparing the plans by Mr F J Hargreaves, who had used a similar drive successfully on his small equatorial at Kingswood, Surrey It was with this instrument that he was the first to photograph the comet Grigg Skjellerup at its return in 1927

Thirty one stellar parallaxes were determined with the Thompson 26 inch equatorial during the year, bringing the total up to date to 400 A useful economy has been introduced of taking two parallax fields on the same plate this halves the time spent in development

The 30 inch reflector is being used for the determination of colour temperature of stars The absolute temperatures are obtained by comparison with the positive crater of a carbon arc lamp which is mounted on the roof of the octagon room 600 feet away Twenty four early type stars, distributed as uniformly as possible round the northern hemisphere, have been selected as standards, forty other stars have now been compared with these the comparisons being made at the same altitude in each case Some notes on B type stars of abnormally low temperature were published in the *Monthly Notices* last year

With the astrographic equatorial, plates are being taken for comparison with those taken twenty five to thirty years ago in order to determine proper motions The result of this study for the zones from Decl +64° to +72° is now in the press The sunspot curve gives indications of a double peak in 1926 and 1928 respectively Daily spot numbers both of the whole disc and of the central region, are sent to Zurich for the Bulletin which is published there under the auspices of the International Astronomical Union

The magnetic elements determined at Abinger for the year 1928 are Decl 12 47 0 W Hor Force 0 18564 Vert Force 0 42941 Dip, 66° 37 3 the Decl is diminishing about 12 per annum

The mean temperature of the year ending on April 30, 1929 (misprinted 1928 in the report), was 48° 7 or 0° 8 below the average Frost occurred on 71 days the rainfall was 20 46 inches, or 3 78 below the average March, with 0 038 inch, was the driest month ever recorded at Greenwich

The performance of the two Shortt sidereal clocks has been very satisfactory the temperature in the clock cellar is now maintained at 62° 8 Fahr The progressive increase of losing rate still continues it is proposed to substitute a bob of invar on one of the clocks

Daily comparisons of time are made with Paris, Nauen, Annapolis, and Bordeaux In all four cases the residuals appear to show an annual wave

Allusion is made to the eclipse expedition to Kedah and Siam The total equipment weighed ten tons Unfortunately, no results were obtained in the investigation of the Einstein bending of light, but some results on the corona and prominences were obtained at Alor Star A C D CROMMELIN

Wisconsin Limnology

THE veteran limnologist, Dr E A Birge, together with Dr Chancey Juday and other collaborators, has made several additions to the detailed study of Wisconsin lakes in the *Transactions of the Wisconsin Academy* vol 23, *Proceedings of the American Philosophical Society*, vol 66, and in *Ecology*, vol 8 The Academy papers deal with the temperature of the bottom deposits of Lake Mendota, with the chemical composition of its larger aquatic plants and with the phosphorus content of that and other Wisconsin lakes Temperatures were measured in the mud of Lake Mendota down to 5 metres, in depths of water from 8 m to 23 5 m The data accumulated are used to calculate the annual heat budget At the shallowest station this amounted to 2950 calories per sq cm and 1100 calories at the deepest Preliminary data on the heat budget of Karluk Lake Alaska are given in *Ecology*, July 1927 These are compared with the values given by lakes in Central Europe

Supplementing a previous study of the composition of *Cladophora* and *Myriophyllum*, analyses of *Vallisneria* and *Potamogeton* are now given Rickett had previously shown that Mendota, 10 4 sq kilometres in area yielded, in dry weight 1112 metric tons of *Potamogeton* and 736 of *Vallisneria* Of these, the latter has an ash content of 25 2 per cent, the former 11 4 per cent Their influence upon the water and soil of the lake must, therefore be very considerable The analyses are unusually detailed and record the amounts of certain important minor constituents, such as phosphorus, iron manganese, and silica, which are frequently omitted

The organic matter content of lake waters is considered in a preliminary survey (*Amer Phil Soc*), which, however, contains analyses from forty four lakes These are grouped into *autotrophic*, which derive their organic matter from internal sources only, namely, from the phytoplankton and attached vegetation and *allotrophic*, into which drainage brings soil and marsh extractives For each lake the organic matter is a fairly definite quantity, showing no great variation either with depth or time This is in striking contrast to the oxygen content, which is often greatly reduced in the deeper cold water, the hypolimnion, this during summer remains unmixed with the warm epilimnion

Analyses were made of the waters of eighty eight lakes to determine the soluble phosphorus existing as phosphate, also the phosphorus in organic combination This was done in order to ascertain whether the simple yearly cycle, observed in the open sea, could also be traced in these lakes The marine workers found a winter maximum and a minimum in early summer, lasting until August, the surface waters being, during the summer, almost or quite devoid of inorganic phosphorus, and the deeper waters—in shallow seas—being much reduced In the lakes, however, observations made in May, soon after the disappearance of the ice, and in July or August, were complicated by two factors—the very minute amount of inorganic phosphorus and its regeneration from the plankton Accordingly, no such simple seasonal cycle was revealed Possibly the rate of regeneration, rather than the absolute amount of phosphorus, may here be the limiting factor

In *Ecology* (8, No 4, 1927) an account is given of the occurrence of two crustacea, *Pontoporeia affinis* and *Mysis oculata* var *relicta*, which are regarded as 'marine relicts' Though thoroughly studied in Europe, their American distribution is imperfectly known It was found that *Pontoporeia* occurs chie[illegible] oxygen may fall below 1 c c per litre The breeding season extends from December to May *Mysis* was found in two lakes During summer it remains on the bottom during daytime, but may even reach the surface at night The breeding season extends from October to May

University and Educational Intelligence

CAMBRIDGE —The solicitors carrying out the will of the late Mr John Humphrey Plummer state that, in view of the many conflicting and wholly unauthorised statements that have appeared, the time has arrived when some authoritative statement should be made concerning the benefaction which will accrue to the University The residue of the estate is to be applied in perpetuity for the promotion and encouragement of education in chemistry biochemistry, physical science or such other allied subjects in the University as the trustees shall think fit The testator further expressed his desire and intention that his trustees should as soon as possible establish and endow a professorship or professorships each of the annual value of £1200 in accordance with a scheme to be devised The testator further expressed the wish that the trust should be known as the John Humphrey Plummer Foundation The trustees are advised that the estate should yield an income to the University of approximately £10 000 a year

The Drapers Company has made a grant of £1000 per annum for a further period of 10 years to the School of Agriculture

Dr H B Roderick and Mr G Stead have been reappointed University lecturers in medicine

EDINBURGH —Principal Sir Alfred Ewing announced at the meeting of the University Court on May 27, in connexion with the proposed internal reconstruction of the medical buildings at Teviot Place, that gifts have been intimated for this purpose of £20,000 from Sir William Dunn's trustees, and £35,000 from the Rockefeller Foundation, making a sum of £55,000 in all This, along with other moneys available, now secures the carrying out in its entirety of a scheme drawn up by Mr Balfour Paul, architect, in consultation with the heads of the departments concerned, whereby the medical buildings, erected in 1880 will be radically altered in their internal arrangements, so as to bring them in line with the most modern requirements for teaching and research The external aspect of the buildings, as designed by the late Sir Rowand Anderson, will remain unaltered The work will be begun in the summer vacation Certain portions of the reconstructed building will in future be associated with the name of Sir William Dunn in recognition of the generous gift from his estate

LONDON —The following doctorates have been conferred D Sc in metallurgical chemistry on Mr J C Hudson (Imperial College, Royal College of Science, and Royal School of Mines), for a thesis entitled "Third (Experimental) Report to the Atmospheric Corrosion Committee (of the British Non Ferrous Metals Research Association)", D Sc in agricultural chemistry on Mr V Subrahmanyan (Rothamsted Experimental Station), for a thesis entitled "Biochemistry of Waterlogged Soils"

MANCHESTER —Mr J B. M Hay, lecturer in engineering, has resigned on his appointment as head of the Civil Engineering Department in Bradford Technical College

Applications are invited for two Grisedale biological scholarships in, respectively, botany and zoology, each of the value of £200 Applications should reach the

READING.—Dr. T. Franklin Sibly, principal of the University of London since 1926, has accepted the invitation of the council to become vice-chancellor of the University in succession to Dr. W. M. Childs, who is retiring in September next.

AT the time of going to press, the following results of Parliamentary elections in University constituencies have been announced:—Cambridge (2): Mr. J. J. Withers, Mr. G. H. A. Wilson. London: Dr. E. Graham Little. Combined English (2): Sir Martin Conway, Miss E. Rathbone. Wales: Mr. E. Evans. Queen's, Belfast: Col. T. Sinclair.

THE New Education Fellowship (English section) gives prominence in its annual report for 1928 to the subject of parent education. At a conference which it called last September, it was resolved to form a National Council for Parent Education and Child Study, and a provisional committee was appointed with Dr. Basil Yeaxlee as chairman to undertake the preliminary work with the aim of correlating and extending the efforts of existing organisations for forming parent-teacher associations all over Great Britain, child psychology study groups, training of study group leaders, publication of pamphlets and magazines for parents, formation of libraries, panels of speakers, etc. The movement will be stimulated by a visit to Great Britain this summer of some of the leaders for similar movements in America and by the fifth international New Education conference to be held at Elsinore on Aug. 8–21. The Fellowship, of the English section, of which Sir Michael Sadler is president, besides organising biennially international conferences, maintains libraries and information bureaux, publishes magazines and in other ways promotes co-operation between educationists and between parents and teachers. Its watchwords are: Release spiritual and creative power in the child; study and respect the child's individuality; educate through innate interests; encourage co-operation rather than competition; co-educate; educate for service. The general theme of the Elsinore conference will be "The New Psychology and the Curriculum".

A CENSUS of graduate research students in chemistry in the United States in 1927 shows that they numbered 1934 in one hundred and forty universities, as follows: in organic chemistry 570, general and physical 430, industrial and engineering 183, physiological 134, inorganic 116, agricultural 89, colloid 79, analytical 75, nutrition 58, catalysis 28, food 27, sanitary 25, photographic 25, metallurgical 21, five other sub-heads 74. The census has been taken annually for four years by the Research Information Service Division of the National Research Council, Washington, and discloses a steady growth in the total number of such students (1700, 1763, 1882, 1934), although under the various sub-heads the numbers fluctuate. In addition to these students, 1047 members of the faculty staffs were engaged in chemical research. In the pamphlet giving the results of the census (*Reprint and Circular Series of the National Research Council*, No. 84. Washington, D.C.: National Academy of Sciences, price 20 cents) figures are given separately under each sub-head for each university, together with the name of the head of the department of chemistry. In the same pamphlet are statistics showing the number and amounts of fellowships and other stipends received by graduate students in chemistry in 119 universities in the United States in 1927–28. Of the total number of such students, 45 per cent received no financial assistance either from the university or from outside organisations. More than one third of these self-supporting students (418) belonged to Columbia University, New York.

Calendar of Patent Records

June 9, 1683.—Great public interest was aroused by the patent granted on June 9, 1683, to Robert Fitzgerald and others for his process for obtaining fresh from salt water. A previous patent granted in 1675 to William Walcot for a similar invention was voided by the Privy Council on the ground that it had not been put into operation, and it is said that Fitzgerald's prescription, certified by Robert Boyle, was sent by Charles II. to the Lord Mayor "to be kept lest a secret of so great importance might come to be lost". But it was Fitzgerald's process that eventually proved a failure and Walcot's that triumphed. In 1695 an Act of Parliament was passed restoring Walcot's rights and granting him a 35 years' monopoly.

June 9, 1842.—The direct-acting steam hammer first reduced to a practical form by James Nasmyth was patented by him on June 9, 1842.

June 12, 1704.—The rise of the Irish linen trade is due very largely to Louis Crommelin, the leader of a small band of Huguenots settled in Belfast, who contracted with William III. to supply the requisite machinery and material and to teach the Irish the art of linen manufacture in return for the interest on his expenditure and £800 a year. On June 12, 1704, the Signet Office in London records a patent granting to the Board of Trustees of the Linen Corporation and the Lieutenant Justices of Ireland a yearly sum of £1180 for ten years for the purpose of encouraging the manufacture, the payment of £200 a year to Crommelin "for his paines and care in carrying on the work", and £120 a year to three assistants, with a pension of £60 a year to a French clergyman for the Huguenot colony.

June 12, 1806.—The purification of coal gas with lime was suggested in the early days of gas manufacture. Edward Heard, on June 12, 1806, patented a process in which the lime was charged with the coal in the retorts, but the proposal did not come into general use until it was reintroduced by W. J. Cooper in 1882.

June 13, 1551.—The first patent of which there is any record in France is that granted for ten years by Henry II. to Theseo Mutio, an Italian, on June 13, 1551, for making all kinds of Venetian glass. The manufacture was not successful, but the experiment paved the way for the subsequent encouragement of Italian workmen by Henry IV.

June 13, 1772.—William Tutin's is a noteworthy name in the history of the manufacture of shoe buckles, an important Birmingham industry in the eighteenth century. Tutin was the inventor of the alloy—made of brass, antimony, and tin—called "Tutania", of which most of the buckles of the period were made, and on June 13, 1772, he was granted a patent for a process of japanning buckles "so as to equal and far exceed in cheapness and wear the common blue coloured buckles, which are coloured by the heat of the fire, and are liable to be damaged by wet".

June 13, 1922.—Insulin, the pancreas extract used in the treatment of diabetes, was isolated by Dr. G. F. Banting and Dr. C. H. Best, of the University of Toronto, and in order to safeguard the public interest the method of extraction was patented in Great Britain on June 13, 1922. The University of Toronto invited the Medical Research Council to assume the responsibility for its production in Great Britain and conveyed the patent rights to the Council as a free gift. The word 'insulin' is due to Sir Edward Sharpey Schafer, who coined it about 1911 in anticipation of the discovery.

Societies and Academies

LONDON

Royal Society, May 30 — **O W Richardson** and **P M Davidson** The energy functions of the H_2 molecules The terms in the expansion of the force function are determined for certain states by various methods and show satisfactory agreement Negative total energies, heats of dissociation and other constants of about thirty H_2 states are tabulated Curves are drawn for the mean kinetic energy of the electrons of certain states at various nuclear separations An appendix contains a theorem on the mean energy of a system of particles in any condition of periodic motion, when some of the particles are fixed — **E K Rideal, C P Snow, F I G Rawlins**, and **A M Taylor** Infra red investigations of molecular structure (1) — **C P Snow, F I G Rawlins**, and **E K Rideal** Infra red investigations of molecular structure (2) The vibration rotation band spectrum of nitric oxide proves to be a fundamental with its centre at 1882 9 cm^{-1}, with the fine structure consisting of P, Q, and R branches with at least 42 rotation bands in each of the P and R branches The molecular constants derived from the separation of the fine structure bands (3 35 cm^{-1}) corresponds almost exactly with those obtained from electronic band spectral data The presence of a Q branch is in accordance with the gyroscopic character of an odd electron molecule The facts relating to the ground state of nitric oxide, its physical magnitudes, and its electronic angular momentum about the nuclear axis, form a consistent whole - **A Müller** The connexion between the zig zag structure of the hydrocarbon chain and the alternations in the properties of odd and even numbered chain compounds Starting from the fact that the CH_2 groups are arranged in a zigzag line it is shown that there must exist an essential difference in the structure of the odd and even numbered substances This difference accounts for the alternations of properties — **O W Richardson** and **F S Robertson** The emission of soft X rays by different elements at higher voltages — **L P Davies** The soft X ray emission from various elements after oxidation The effect of oxidation on the total soft X ray emission from the following elements has been studied Silicon, manganese iron, cobalt, nickel copper, molybdenum palladium, and tungsten The efficiency of the oxide seems to be the average efficiency of the oxygen and element present — **D L Chapman** and **W K Hall** A study of the catalysis by silver of the union of hydrogen and oxygen The new method of Hughes and Bevan was used and the conclusions confirmed by direct measurements of the falls of pressure which occur when the gases, separately and mixed together, are brought into contact with a large surface of silver The mechanism of the action seems to be one of alternate reduction and re oxidation of an oxide film The fact that a film formed at low temperature is more effective than one formed at a higher temperature suggests that some of the molecules of silver oxide in the former are in relatively unstable positions, and therefore more active chemically — **R H Fowler** and **A H Wilson** A detailed study of the 'radio active decay' of, and the penetration of α particles into, a simplified one dimensional nucleus The authors solve exactly for a simplified nucleus the problem of α particle disintegration (determination of the *complex* characteristics of the wave equation with the proper boundary conditions), and discuss the converse problem of the penetration of an α particle into the nucleus from without — **G I Finch** and **D L Hodge** Gaseous combustion in electric discharge (3) Combustion of dry detonating gas in the direct current discharge is primarily determined by the ionisation of both the constituent molecules of the gas Electrostatic forces keep apart positively charged ions, unless such forces are counteracted by some other agency, one such agency is negatively charged metal atoms sputtered from the cathode which, by forming electrically neutral metal gas complexes with positive ions, overcome electrostatic repulsion and thus enable combustion to proceed — **G I Finch** and **J C Stimson** The electrical condition of hot surfaces during the adsorption of gases (3) A hot platinum surface exhibits a charge when *in vacuo* or in contact with gases With alternate treatment with oxygen and hydrogen at 500° C, it will exhibit a charge in hydrogen or *in vacuo* at room temperature Heating at 850° destroys such superactivity The charge due to any gas can be rapidly removed by evacuation at 850° The destruction of the superactive condition is due to a structural change in the arrangement of the surface atoms akin to sintering — **J M Robertson** An X ray investigation of the structure of naphthalene and anthracene Using the rotating crystal photographic method, the general and statistical considerations of the reflections indicate a periodic structure parallel to the c axes of the crystals Geometrical structure factors are developed and the dimensions of the molecules calculated differ only slightly from those of Bragg's tetrahedral structure Thus the tetrahedral properties of the carbon atom are maintained in aromatic structures — **K Majumdar** The arc spectrum of chlorine The spectrum has been photographed in the region λ6400 8700 The ionisation potential is calculated as 13 1 volts — **K R Rao** The arc spectrum of germanium Observations have been extended to λ1630 and about fifty new lines have been added most of which have been classified The ionisation potential of Ge I is 8 09 volts approximately — **U Nakaya** On the emission of soft X rays by different elements, with reference to the effect of adsorbed gas The absorption of these rays increases with the amount of the adsorbed gas molecules on the photoelectric plate, while the excitation decreased with the presence of gas molecules Reliable data were secured by bombarding the photoelectric plate and target to red heat in the highest vacuum and afterwards reducing the oxide films on these surfaces with hydrogen - **N F Mott** The scattering of fast electrons by atomic nuclei The scattering of electrons by an atomic nucleus is investigated, using the wave equation of Dirac and a scattering formula obtained which gives the spin relativity correction to be applied, for fast β particles, to the usual Rutherford formula — **L J Freeman** Further investigations of the spectrum of ionised nitrogen (N II) Nine terms belonging to a quintet system have been identified and two new terms of the triplet system Some 75 lines have been newly classified — **A E Gillam** and **R A Morton** The absorption spectra of halogens and inter halogen compounds in solution in carbon tetrachloride — **R A Frazer** and **A J Duncan** On the criteria for the stability of small motions — **R A Frazer** and **W J Duncan** On the numerical solution of equations with complex roots — **G C McVitie** On Einstein's unified field theory

Physical Society, May 10 — **W E Sumpner** Heaviside's fractional differentiator The paper deals with (1) Heaviside's experimental methods, (2) the index operator, its definition and justification, (3) its use with Leibnitz's theorem, (4) its use with binomial and exponential expansion, (5) functions of the operator, (6) Heaviside's operators, (7) examples, (8) the impulse function — **J H Awbery** :

A simple method of fitting a straight line to a series of observations The method has a rational basis and can be carried out much more quickly than the method of least squares —E W H **Selwyn** Arc spectra in the region λ1600–λ2100 A simple method is described of photographing ordinary arc spectra down to about λ1600 Additions have been made to the analysis of the spectra of Mg I, Be I, and B I — **K R Rao** The spectrum of trebly ionised thallium —**G A Wedgwood** The elastic properties of thick cylindrical shells under internal pressure An experimental investigation of the usually accepted theory Longitudinal and diametral extensions were determined of a number of steel cylinders subjected internally to hydrostatic pressure, the cylinders being closed at the ends by covers secured to the shell itself Discrepancies seem to be due to the non isotropic nature of the material

PARIS

Academy of Sciences, April 29 —**Henri Villat** The alternating vortices of H Bénard in a canal of finite width — **E Mathias** Contribution to the study of fulminating matter Its two modes of decomposition A review of descriptions by witnesses of cases of globular lightning Certain of these describe the dissipation as without noise, in others, and these form the majority the disappearance was accompanied with very violent explosions —**J A Schouten** The geometrical signification of the semi symmetrical property of an integral connexion, which leaves invariant the fundamental tensor —**Georges Durand** A manner of conceiving the theory of envelopes — **D Pompeiu** Certain systems of linear equations and an integral property of functions of several variables — **René Lagrange** Certain functions associated with the functions of Legendre —**E Hille** and **J Tamarkin** A relation between the results of Minetti and Valiron —**Alex Véronnet** There are three distinct dynamics, and three only, corresponding to the three spaces of Euclid, Riemann, and of Cartan —**Lucien Féraud** Some applications of Pfaffian systems —**René Lucas** Remark on the equations of electromagnetism — **Neronoff** The law of attraction —**R Hocart** The diamagnetism of some binary halogen compounds The diamagnetism of the ions is not strictly additive, and hence it is not possible to describe the diamagnetic properties of substances by means of a single coefficient The coefficients of solutions of hydrochloric acid, common salt, and potassium chloride are given, the accuracy being from 0 1 per cent to 0 3 per cent — **G Föex** The diamagnetism of the crystal of azoxyanisol and the precession of Larmor —**Jean Becquerel** and **W J de Haas** The fundamental law of paramagnetic magnetisation of a crystal and the law of paramagnetic rotatory dispersion —**J Gilles** The trajectory *3d* in the ionised atoms P II, S II, S III, and Cl III Quadruplets of Cl III —**Charles Nordmann** A new method for the reproduction of colours —**Marinesco** The structure of solutions of gelatine A study of the relations between the dielectric constant of gelatine solutions and their concentration —**Nahmias** The evaluation of the α radiation of the active deposit of actinium by the measurement of its β radiation —**H Herszfinkiel** and **H Jedrzejowski** The conditions of formation of groupings of radioactive atoms —**René Delaplace** and **G Reblère** The irradiation of ergosterol the action of the ultra violet rays of quartz and of the soft X rays Diagrams are given showing the changes in the ultra violet spectrum of ergosterol produced by various times of exposure to ultra violet light Soft X rays produce effects qualitatively similar —**Antoine Willemart** The isomerisation of some acetylene carbinols into ethylene ketones The transformation of alcohols of the type $R_1R_2C(OH)-C{\equiv}CR_3$ into the ketones $R_1R_2C{=}CH-CO-R_3$ either by alcoholic sulphuric acid or through the chlorides is a general reaction Several examples are given —**Huan** The action of ethylmagnesium bromide on the tetrethyl diamide of succinic acid —**L Royer** The possible asymmetry of the corrosion figures obtained by an active isotropic liquid Results on the corrosion of calcite crystals are given which are in general agreement with the views of Hettich **A Amstutz** The crystallophyllian conglomerates of Mayombe, in the French Congo —**P L Violle** and **A Giberton** The antitoxic properties of calcium towards sparteine sulphate A guinea pig survived indefinitely the injection of a mortal dose of sparteine sulphate when the latter was mixed with a solution of calcium chloride —**Marc Bridel** Researches on the variation of colour in plants in the course of their drying The glucoside of *Lathræa clandestina* is aucuboside (aucubine) **Charles Pontillon** The pigmentation of *Sterigmatocystis nigra* cultivated on fatty media The yellow coloration sometimes observed in *Sterigmatocystis nigra* cultivated on fatty media is a consequence of the lack of homogeneity of the culture medium due to the mode of preparation of the mineralised gelose solution **René Wurmser** and **Jean Geloso** A glucose derivative a constituent of the oxido reduction equilibrium of the cells —**Mme L Randoin** and **R Lecoq** The primordial rôle of the alimentary equilibrium in the utilisation of lactose —**Edouard Chatton, André Lwoff,** and **Mme Marguerite Lwoff** The infraciliatures and the genetic continuity of recessive ciliary systems

Science in the Public Service and Industry

WE commented last week upon the appointment of a committee to inquire into matters affecting the functions and staffs of certain research and experimental establishments of departments of Government This inquiry is, of course, separate from that of the Royal Commission on the Civil Service which Mr Baldwin recently announced would be appointed We trust that the change of Government will not mean that this Commission will be dropped A really wider issue than that of the position and functions of the technical expert in the Civil Service is involved, indeed the time is ripe for an inquiry into matters affecting the position and responsibilities of the man of science and the technologist generally, in industry as well as in the public services

For some considerable time a suspicion has existed that matters affecting the status and responsibilities of the technical expert are very far from satisfactory in Great Britain As regards the public services, it is possible nowadays, more or less, to gauge the situation, owing to the existence of the many specialised vocational associations which have, in recent times, been formed within the Civil Service and the Local Government Service for the purpose of protecting the interests of their members, practically all these associations periodically issue publications dealing with their activities, and thereby give an insight into the nature of the problems to which attention has been devoted Furthermore, the Royal Commission on Local Government appointed on Feb 14, 1923, under the chairmanship of Lord Onslow, has during the past twelve months taken evidence from some of these vocational associations, particularly in relation to the duties and status of the technical offices under the local authorities, in this evidence the practice of the central government has been touched upon, and its attitude towards its technical officers has been contrasted with that of the local authorities towards their chief officers who are engaged mainly on technical duties

In industry, no institutions with objects identical with those of the vocational associations referred to above exist, consequently, it is more difficult to obtain generalised information regarding the status and responsibilities of those engaged on the technical side of industrial and commercial undertakings In view of the great national importance of the subject, individual inquiries have been addressed in relation thereto to a number of persons engaged on technical duties in some of our

industries As might be expected, the information collected shows that in industry the conditions vary very widely, and also that the attitude of the chief officials responsible for the conduct of the affairs of various important concerns differs to some extent in relation to the status and responsibilities which should be assigned to the section of the staff which deals with the technical work In some cases the chief officials are unresponsive to the changing conditions of the times (needless to say, to the detriment of the businesses they control), whilst on the other hand, happily, many such officials are broad minded, progressive, and ever ready to meet the altered, and altering, conditions imposed by the more intense trade competition arising from the more exacting requirements due to increased scientific knowledge and to the high technical skill and ability of the staffs of their foreign competitors

Our inquiry into this subject has disclosed the fact that in industry old prejudices are gradually dying, and that, in recent times, a considerable improvement has taken place in the status of the men of science and the technologists who follow their careers in the commercial world There is still room, of course, for further improvement, which will no doubt come about in time, the matter seems to depend upon two factors, namely, on the introduction in our industrial enterprises of an organisation adapted to meet the very complex technical requirements of to day, and on the willingness of the technical expert fully to qualify himself for the more important administrative posts by devoting his time not only to the study of subjects of a strictly scientific and technical kind, but also of those bearing on the administrative and economic aspects of his work

The improvement in the status of the man of science and technologist to which attention has been directed is due, it has been suggested, to the rise and growth of the electrical industry It has been pointed out that many of the successful businesses connected with this industry have been founded, developed, and managed by men who have had the advantage of a scientific education and of a technical training, many of the most important posts are still held by a type of man with similar qualifications Being an entire new comer, and probably also by reason of the fact that much technical knowledge was involved in almost every decision, this industry was not hampered at its birth by some of the harmful traditions that have tended to limit the sphere of usefulness of the technician in the same way as has been, and still is to some extent, the case in some of the older ones The new policy has very greatly benefited the electrical industry and has enabled it to reach a flourishing condition

Now, a very cursory examination of the information contained in books of reference indicates that the improvement in the status of the technician is not confined to the electrical industry, almost simultaneously with its birth an infection seems to have spread to other industries It is on record that in 1883, when the late Sir William (afterwards Lord) Armstrong first founded his famous Tyneside shipbuilding works, he entrusted the organisation and the directing of this establishment to a technician, who some years later became Director of Naval Construction and Assistant Controller of the Royal Navy At subsequent dates, some of our railway companies selected officers from the technical side of their undertakings for high administrative posts Again, the chemical industry affords instances of chemists who have risen to the control of huge interests and have done well as administrators Men with technical knowledge and experience are also now occasionally appointed as directors on the boards of companies, this is so not only in the cases alone of those concerned with activities of an industrial kind, but it also applies equally to those whose interests are mainly financial or commercial

Apart from the government services and industry, there are the great municipal services The Royal Commission on Local Government now sitting has received a considerable volume of evidence on the aims and objects of the various vocational associations by witnesses representing them, and questions have also been raised by other witnesses as to the desirability, or otherwise, of arranging for interchanges of duties on the part of civil servants and local government officers by temporary transfers of staff from government departments, particularly the Ministry of Health, to the offices of local authorities, and vice versa Moreover, a proposal involving a fundamental change in the constitutional fabric of municipal government has also been put forward, namely, one relating to the appointment in our municipalities of a 'chief officer' corresponding to the burgomaster, who is supreme in relation to municipal affairs in certain continental cities, or of a person possessing the authority and the responsibilities of the city manager who is now in charge of municipal affairs in many important American cities Neither proposal, however, is given much support by local government officers

The town clerk, who is generally a member of one of the legal professions, is, by an almost immemorial custom, recognised as the principal officer of the Local Authority, he is *primus inter pares*, and, apart from the particular duties of his own department, co ordinates the various services of the council, in order to avoid overlapping and to prevent a course being taken by one department without consideration for its effect on another department It is, however, recognised that it would be most improper for a town clerk to criticise or interfere with a technical officer in the carrying out of the technical duties assigned to him, that is to say, the technical officers under a local authority severally exercise their functions independently of the town clerk The practice of local authorities differs, therefore, very widely from that of government departments, in the latter case, the technical branches are elaborately con trolled by the secretary's department

Some of the members of the Royal Commission appear to have been exercised in their minds with regard to the difference of treatment meted out to the two types of officers, the administrative and the technical, in the national civil service and in the local government service, in consequence, questions were put to some of the witnesses with the view of eliciting the reasons why in the latter service it is those with technical qualifications who hold the positions of 'chief officers', and it is considered that there is no field in it for the person without technical qualifications—the 'skilled ad ministrator'—although in the case of the Civil Service the former type of official "did not get to the top of it", whereas the latter type did so invariably

It has been pointed out that the difference in the treatment of the two types of officers in the two services may be accounted for historically, whereas the first services entrusted to a municipal corpora tion were of a character which required technicians at the head of them, on the other hand, the respon sibilities of government departments originally involved the consideration of problems in which the administrative aspect predominated It is further suggested that county and municipal councillors themselves do the administrative work, and rely directly on their officials for technical advice A century ago, ministers of the Crown were able to do, and personally did, a great deal of the administrative work of their departments, but, with the increasing complexity of the problems to be dealt with, the methods then in vogue went out of date and had eventually to be abandoned The system which was introduced later for dealing with the work of government departments has, in its turn, become obsolete

In the evidence given before the Commission, strong adverse criticisms have been made regard ing the narrow rules of the Civil Service, which, as a matter of practice, prevent an officer on the technical side, however well fitted and qualified he may be for the position, being promoted to the higher administrative posts In view of the fact that administrative ability of the first rank is so rare, the policy which prevails in the Civil Service in relation to this matter has been char acterised as being inexpedient, short sighted, and unjust

It is essential that ministers of the Crown should frankly recognise that government departments have completely outgrown the organisation with which they are now endowed, and even that their own positions therein, and the functions they are attempting to exercise, which are very similar to those of a general manager, no longer conform with the requirements of the day

Alterations of a far reaching character are, in consequence, needed in the organisations of our government departments One of the principal features of the reconstruction of such departments should be such as to provide that the functions assigned to ministers in charge of government de partments shall correspond with those of a chairman of a board of directors, or of a commission, and that they shall be aided directly by a body of highly qualified technical experts occupying positions somewhat similar to those of the directors of a company, and be given a distinctive title, for example, they might appropriately be called 'commissioners' If such a reform was carried out in a whole hearted manner, ministers would be placed in a better position than at present to obtain the technical advice required in connexion with the formulation of their policies, since it would reach them at first hand If, further, each of these 'commissioners' was also charged with responsibility for both the administration and the technical work of the various specialised branches of a government department, immediately under the direction of the responsible minister, the management of the public services under the central government would be more efficient and economical than is the case to day, and the ministers themselves would also be placed in a position to exercise their proper functions more effectively, and, consequently, their usefulness and the value of their work to the State would be enormously increased

Shellfish Pollution

Ministry of Agriculture and Fisheries Fishery Investigations, Series 2, Vol 10, No 1, 1928 *Report on Mussel Purification, being an Account of the Establishment of a System of Purification of Polluted Mussels, of the Experimental Work upon which it is based, and of certain General Considerations and Suggestions regarding the Sewage Pollution of Shellfish in its Public Health Aspect* By Dr R W Dodgson Pp xvi + 498 + 16 plates (London His Majesty's Stationery Office, 1928) 21s net

THIS encyclopædic summary and critical analysis of our knowledge of shellfish pollution will long remain the standard work of reference on a difficult problem hitherto baffling even the experts It is thus an essential addition to every up to date public health library But to public health authorities it is also a conspicuous milestone of progress, in that it records how scientific research, by evolving a method proved reliable through a dozen years of extensive practical trial, has solved the problem of purifying sewage polluted shellfish Seldom, indeed, does an official report on practically applied science reveal so many and so varied abilities as this its erudition, lucid presentation and scientific interpretation of facts, shrewd judgment, and sound business sense—all are so freely interspersed by touches of 'pawky' humour as to make its perusal a keen pleasure

Initially, Dr Dodgson reviews fully the literature on the existence and classification of human diseases attributed to eating shellfish 'Mussel poisoning', which is very fully discussed, is classified into three categories the erythematous, the paralytic, and the bacterial food poisoning type The characteristics of the first two, and the points to which attention is to be directed in making a differential diagnosis, are clearly set forth There should in future be no excuse for the confusion which has hitherto existed in some quarters in connexion with these conditions Dr Dodgson's analysis of the evidence establishes two points of much importance to the consumer, namely, that the erythematous type ('musselling') is never fatal, whilst the danger of contracting the fatal paralytic type is, if elementary precautions and common sense are exercised, for practical purposes negligible

The author then considers the correlation of shellfish pollution and certain human infections His initial six months' study of the physiology of the mussel was rewarded by the discovery of the cardinal fact that it filters from the water passing through it all suspended solids—including infective germs discharged by sewers into estuaries, which are most grossly polluted at low tide when shellfish are gathered Following up the trail of infection, he found untreated sewage entering estuaries from many forgotten sewers, the pollution from which was, in some cases, particularly pernicious, for example, that from isolation fever hospitals In one instance excreta from an enteric patient were discharged from a sewer mouth within 50 yards of a mussel bed on to which they flowed so rapidly that germs might enter the mussels within three minutes of being voided by the patient! This fully evidences the risk of human infection by the 150,000 cwt of mussels eaten annually, mostly uncooked, in Great Britain, particularly when, as Dr Dodgson indicates, the fresher the fish the greater is the risk of its retaining and passing on infection

The general position is summed up as follows (p 119)

"As long as dirty food—*polluted* shellfish—is used for human consumption, a serious gap must exist in the defences erected by public health effort against typhoid and other serious disease This gap is not only serious, but is one of the most pernicious of all possible gaps, for it means that we are permitting the infective material from typhoid fever patients and typhoid carriers, and that responsible for other grave diseases, to be poured on to a living article of food, so constituted as to be capable of collecting and concentrating within itself such infective material from an enormous volume of water, and, having permitted this to happen, we allow the concentrated infection to be distributed all over the country, just when we had hoped and believed that we had safely got rid of it, once and for all"

A review of remedies previously proposed shows the impossibility of keeping all sewage from all edible shellfish, and the impracticability of sterilising polluted shellfish by heat or by chemicals While urging that sewage from hospitals housing such cases as enteric should be compulsorily sterilised, chemically or otherwise, prior to discharge into any watercourse, the author shows that this method cannot be reliably or economically applied to the host of other sewers now discharging into our estuaries This section concludes with an able and comprehensive review of existing legal powers, which are shown to confer upon local authorities means of enforcing the simple and effective method of shellfish purification described below

The practical outcome of apparently abstract

research is aptly illustrated To aid in studying the course of water currents within the mussel, Dr Dodgson coloured water with fine carmine powder, and thus discovered that, as the water circulated within them, the mussels filtered off all the carmine, and extruded it firmly entangled in mucoid threads (fæces and pseudo fæces) which resisted disintegration for more than a month in still water Experiments proved that bacteria were similarly filtered off, and that even heavily polluted mussels rapidly freed themselves from polluting germs in water of suitable salinity and at ordinary temperatures Even at freezing point or there abouts similar results were obtained during the night or in artificially produced darkness In running sterile water three hours might suffice for the elimination of all bacteria

This remarkable result is largely achieved by the mussel's gills, which consist of a network of fine ciliated filaments The ciliary currents cause the water to circulate between the filaments suspended matter, including bacteria, being filtered off and becoming entangled in sticky mucus, finally to be extruded from the shell either via the gut (as fæces) or directly via the marginal recurrent ciliary stream (as pseudo fæces) As a single large mussel may thus pass through its body in 24 hours as much as 14 gallons of water, this purifying process is obviously a most powerful factor, and its cleansing action is not aided by the use of water containing active chlorine, because any disinfectant strength of chlorine inhibits or actually arrests the physiological activities of the mussel—thus leading to the retention of bacteria in the mussel body, which would otherwise have extruded them

The practical outcomes of these researches have proved of the utmost value, alike to consumers and purveyors of shellfish and to public health authorities That value lies in the discovery and proof of the fact that there is available a trust worthy, cheap, and simple process, whereby shell-fish—although gathered from polluted estuaries—may be rendered as nearly safe for human consumption as any reasonable authority can require The stages of that process, as regards mussels, for example, are as follows

(*a*) Sea water, pumped into a tank, is sterilised from all germs by adding to it 3 parts per million of active chlorine derived from bleaching powder

(*b*) Any residue of active chlorine remaining after a night's exposure in the tanks having been removed by hyposulphite, the water is then run into other tanks containing mussels spread two-deep upon wooden grids (the mussels having initially been hosed with high pressure fresh water to remove adherent mud) In this sterile, unirritating water, the mussels function perfectly, and eject practically all infective germs from their bodies during the ensuing night

(*c*) The water is then run off, and the ejected mucoid fæces and pseudo fæces are hosed away As an extra precaution, stages (*b*) and (*c*) above are repeated

(*d*) Any germs on the outsides of the shells are removed by exposing the mussels to a bath of water containing active chlorine in solution (3 parts per million)

(*e*) The mussels are loaded into sterilised sacks, which are sealed before dispatch to market with lead seals stamped 'M A F Conway', and bearing the date of dispatch

As thus carried out, this process is so effective that mussels so polluted as to contain 600 sewage germs per cubic centimetre (about a salt spoonful) of their substance, are so purified that this number is reduced in many instances to none, in most cases to less than three, and in almost all to less than five In comparison with the gross bacterial pollution of various articles of food which are con sumed uncooked, such a degree of freedom from germs is truly remarkable, as initiating a new standard of cleanliness for foods

From the business aspect no objections are forth-coming, for the process may be deemed capable of paying for itself on the basis of an output of 8000 bags per annum, and a charge of 1*s* 6*d* per bag of 140 lb of mussels purified, the capital expenditure varying from £3000 to £4500 according to site chosen From the administrative point of view, the working and control have been proved, by some years of trial, capable of being carried out with smooth effectiveness by an adequately trained tank superintendent and one unskilled assistant

This valuable report thus introduces a notable contribution to our means for preservation of the public health, and, as such, will be welcomed by all upon whom that responsible duty falls That, however, is by no means all the story, for, as Dr E S Russell, the Director of Fishery Investigations, observes in his preface "It is significant that the real key to the problem was found in direct and minute observation of the normal physiology of the mussel" Not only has a solution of a difficult practical problem been found by scientific research, but that research has also added a most interesting chapter to our knowledge of molluscan physiology

Perhaps a still more important contribution to

science has been rendered by Dr Dodgson in this comprehensive report by his skilful and courageous criticism (in Part 3) of bacteriological principles and methods of some antiquity and much in need of the caustic consideration which they receive Here again, research and the original discovery that glucose is formed from the tissue glycogen of shellfish pointed the way to criticism of certain bacterioscopic methods depending on the fermentation of lactose, which, though based on perfectly sound general principles, may be quite misleading when applied to the particular case of shellfish analysis But the "cogent evidence" to which Dr Russell refers in respect of this phenomenon and of the errors likely to be introduced by the element of chance in the interpretation of results is as resistant to concentration in a review as it is important from the point of view of the experts It will require an extensive reply from the strictly orthodox

Babylonian Astronomy and Chronology

The Venus Tablets of Ammizaduga a Solution of Babylonian Chronology by Means of the Venus Observations of the First Dynasty By Prof S Langdon and Dr J K Fotheringham With Tables for Computation by Carl Schoch Pp vi + 109 + xvi (London Oxford University Press, 1928) 35s net

THIS is a work of great interest to students both of archæology and of astronomy The story of the many stages that were necessary before a full understanding was reached of the astronomical value of the tablets is as fascinating as a romance The tablets that have come down to us were copies made in the eighth or seventh centuries B C of originals more than a thousand years earlier We are fortunate in possessing a number of different copies of the originals, the calendar dates recorded in duplicate copies are not in perfect agreement, it is a familiar fact both in ancient and modern times that numbers are particularly liable to erroneous transcription We can reasonably ascribe the few discordances that remain in the solution to this cause

The tablets are in the form of omens, stating that such and such configurations of Venus (Nininsi anna is the name used) on given calendar dates will be followed by such and such events on earth *A priori*, such documents would seem void of astronomical value, but convincing reasons have been found for believing that the omens were based on experience, and that such configurations and subsequent events had actually occurred The date of the originals was not even roughly known until Father Kugler announced in 1912 his discovery that a Sumerian phrase that had hitherto been misunderstood meant "The year of the golden throne", and was the date formula of the eighth year of Ammizaduga, commemorating his placing a golden throne and a statue of himself in a Babylonian temple This fixed the date within two centuries or thereabouts, and it was now possible to calculate the positions of Venus for different possible years The fact that transits of Venus usually occur in pairs, separated by 8 years less $2\frac{1}{2}$ days, is well known Any configuration of Venus with respect to the earth recurs after a similar interval of time But when a lunar calendar is used, the recession of the date after 8 years is 4 days, so this calendar is more sensitive than the solar one to a change of date However, an interval of 56 years would bring back the event to the same day of the month, but this would be the month preceding the original one Since the beginning of the year was somewhat elastic in those times, this might bear the same name as the original month, the same thing might even happen after a second period of 56 years, if the dates were given somewhat roughly, or the days of the month wrongly copied, there might be further uncertainty of one or two multiples of 8 years Thus we find that Kugler first adopted the year 1977 B C as the first of Ammizaduga's reign, but later he made it 176 years later in consequence of some arguments of Weidner

Dr Fotheringham then took the matter up at Prof Langdon's request He improved Kugler's calculation in two ways first, by taking into account the accelerations of the sun and Venus which had been found from discussion of ancient eclipses and in other ways, secondly, by noting that the duration of the invisibility of Venus at conjunction with the sun depends on its latitude, which in turn depends on the date in the solar year He reached the date 1921 B C as the first year of Ammizaduga, it is a curious coincidence that the A D date of its first publication was only two years different (1923)

The date 1921 B C is retained in the present publication, and the arguments in its favour have been considerably strengthened With the view of locating the months of the lunar calendar in the solar year, a number of contracts relating to the harvests of corn and of dates have been discussed Kugler made a beginning in this research, but it has been extended Also Herr Schoch devised a

new method, based on the lunar months which were recorded as having had 30 days, this method would not be in itself decisive, but it gives some clue to the actual dates of new moon, it is found to support the above solution Another confirmation is found in the accord between the chronology based on this date and that based on Schoch's identification of the lunar eclipse that preceded the fall of Ur with the one that occurred on Mar 8/9 (Julian) in 2283 B C The record of that eclipse, like the Venus tablets, is in the form of an omen

The book contains a complete chronological list of the kings of Sumer and Accad, Babylonia and Assyria, it combines the deductions from the Weld Blundell prism with those of the present volume It is well to direct attention to the note on p 83 that all the dates of the table before 2300 B C should be made 19 years later, since these had been set up before Schoch's date for the fall of Ur had been adopted Sargon of Agade reigned from 2732 to 2677, and Narâm Sin from 2652 to 2615 Thus Nabu na'id, the last king of Babylon, made an error of some 1100 years in saying that Narâm Sin preceded him by 3200 years

The book also contains discussions on the occurrence of intercalary years, both in Ammizaduga's and neighbouring reigns, these seem to have depended largely on the whim of the monarch There are tables, prepared by C Schoch, for finding approximate positions of the planets, and for obtaining the date of new moon at any epoch between 3500 B C and A D 2000

The full text of the tablets is also given, both in cuneiform and transliterated, with translation and comments by Prof Langdon

A C D CROMMELIN

World History since the War

1918–1928 a Short History of the World By C Delisle Burns Pp 447 (London Victor Gollancz, Ltd, 1928) 16s net

FOR those who desire a compact and trustworthy survey of world history since the War from the political point of view, there is nothing to be had to compare with this book It relies mainly on the much fuller accounts given in the several volumes issued by the Royal Institute of International Affairs, and it adds to them where they have not yet dealt with the particular problem The view suggested is, on the whole, hopeful, and would be more so but for the one serious defect to be mentioned later It points out, for example, the improved stability of Germany since the War "The German Reich is now much more powerful as against any of the local patriotisms of Germany than it was before the war", and again, "whereas the unity of the Russian people was dissolved by the war, that of the German people was confirmed" The real reason for this difference, however, is not hinted at, and it will be found in the defect to be referred to below

There is a wholesome protest, often repeated, against disparaging the increased attention given since the War to the economic aspect of politics "The increase of wealth and decrease of the incidental burden in producing it, is not in the least 'materialistic' The life of the body is the life of the spirit There are not two lives in the common man" The 'common' man, by the way, occurs with rather tiresome iteration and provokes the inquiry who he really is "The neglect of food supply and its incidentals—finance and commerce—by rhetorical politicians and diplomatists is not a sign of their superiority, but of their blindness to the importance of these basic factors on which their own comparative freedom from economic insecurity rests" So far, of course, as these persons do these things, they are open to Mr Delisle Burns's censure But surely they are doing it very little now?

These signs of a somewhat jaundiced eye are trifling and rather interesting blemishes on an excellent piece of work But a word must be said on the really serious point How can anyone, above all anyone of Mr Delisle Burns's knowledge and breadth of mind, offer us "A Short History of the World" without a word on the enormous development and influence of science, and that at a time when its development and influence have been greatest? It is not, as might be urged, a question of limiting the field, for other matters, desirable for a complete view, may be left out without essential damage to the main argument One can write a history of the last ten years without mentioning the poetry and art of the period It would be incomplete, but not vitally mutilated One cannot do so without science, because science is at the base of that shrinkage of the world and that permanent establishment of international relations of which Mr Delisle Burns is as conscious and as firm a defender as anyone To take two crucial examples from the book itself It is because Germany was a scientifically organised and educated country that she survived the War as she did and has increased her coherence, and because Russia was not that she went down, and, on the largest issue which arises in the period, it is because the nations of the West are the guardians of this

scientifically organised society that they must maintain their position vis à vis of the East and the less developed peoples of the globe

It is almost unnecessary to add that these last ten years have also witnessed the most amazing extensions of the scientific spirit above all in astronomy and physics that humanity has ever gained These belong to all mankind they afford the easiest means of binding the nations together and they lift the mind above the atmosphere of jealousy and discord which are so painfully apparent even in a generally hopeful book such as Mr Delisle Burns has given us F S M

Voyages of Exploration to Judge of the Bearing of Hybridisation upon Evolution By J P Lotsy and W A Goodijn 1 *South Africa* (*Genetica Nederlandsch Tijdschrift voor Erfelijkheids en Afstammingsleer* onder redactie von Dr J P Lotsy en Dr H N Kooiman vol 10) Pp viii +315+11 plates ('s Gravenhage Martinus Nijhoff 1928) 35 guilders

DR LOTSY has undertaken during recent years many voyages of exploration seeking evidence of the frequency of hybridisation in Nature in order to assess its rôle in the creation and perpetuation of the diversity in characterisation so abundantly observable Recently with his colleague Dr Goodijn he visited South Africa and in the volume under notice gives an account of the many things they saw The first part of the story concerns itself with forty three plant hybrids distributed over thirteen families

Thereafter the authors turn to a much more interesting topic that of hybrids between different human races so very common in South Africa and yet save for the classical work on the Rehobosh hybrids so far unrecorded The investigation was perforce somewhat hurried and much of that which is written is copied directly from other books which would seem to be mainly impressionistic and uncritical However the chief native races are divided for purposes of discussion into Bantu Bushman and Hottentot linneons and it is suggested that there exist some eight tribes which have had their origin in the crossing of these Quite interesting but definitely anecdotal accounts are given of certain white × black crosses The origin of the de Buys people the Bastaards and Griquas and the Cape coloured is discussed but no really satisfactory conclusion is reached

Finally a number of family histories illustrated with useful photographs is given and these may permit the enthusiast and the expert to identify the ancestry by recognising segregation among the progeny This is always a simple matter in the absence of any standard type Similarly the coloured plates (in a separate folder) illustrating the plant and human crosses are of more artistic than scientific value

Science and Personality (The Terry Lectures) By Dr William Brown Pp ix+258 (London Oxford University Press 1929) 12s 6d net

THIS volume contains the substance of three lectures which were given by Dr Brown in the United States in 1928 and were delivered in connexion with the Dwight H Terry Foundation The material there presented has been amplified by the inclusion of a selection of other papers relevant to the general theme which is broadly a consideration of religion in the light of science and philosophy

Dr Brown commences by a brief survey of the present state of the physical sciences and he then proceeds to examine the condition of the biological and psychological sciences Continuing he deals shortly with the problems of mental unity as contrasted with mental dissociation insisting that here is to be discerned a direct relation to the problems of unity and dissociation in the physical and physiological spheres He then proceeds to consider the various theories which have been advanced to explain the phenomena of suggestion passing on to an examination of the claims of psycho analysis and other forms of psycho therapy The book ends with a discussion of personality in relation to the alleged supernormal phenomena which form the subject matter of psychical research and in this section a full report of a sitting with the medium Mrs Osborne Leonard is printed in order to illustrate the bearing of the trance utterances upon the general question

Although it is obvious that Dr Brown is in favour of trying to reconcile the claims of science with those of religion it is not quite clear in what sense he uses the latter term Again the relation of religion to what he calls the universe and the concept of value which he considers an integral part of his argument are not sufficiently worked out to illustrate the problem of personality and the inclusion of some very dubious examples of clairvoyance towards the close of the volume tends rather to obscure than to clarify the fundamental issues

It is to be hoped that Dr Brown will return to the same theme in another place and develop individual points in his theory more fully than he has found possible in the present volume

Vorlesungen über theoretische Physik an der Universität Leiden Von Prof Dr H A Lorentz Band 4 *Die Relativitätstheorie für gleichförmige Translationen (1910–1912)* Bearbeitet von Dr A D Fokker Ubersetzt von Dr H Stucklen Pp ix+180 (Leipzig Akademische Verlagsgesellschaft m b H 1929) 13 80 gold marks

THIS volume is substantially a translation of the lectures delivered by Prof Lorentz in 1910–12 on what is now called the special theory of relativity with one omission and a few additions The part omitted dealt with gravitation and has been withdrawn as being superseded by Einstein's general theory One addition is an account of later experimental work on the mass of a moving electron The results of Guye and Lavanchy (1916) on

cathode rays of high velocity are described very fully, as they are regarded as removing any possible doubt as to the truth of the Lorentz transformation formulæ Another addition, taken from later lectures, discusses a few specially difficult questions concerning tension, momentum, and energy

The special theory is so well known now that the book calls for little comment The style, as might be expected, is excellent It is characteristic of the author's modesty that he dismisses in a single sentence his own researches which preceded those of Einstein

There is one point in Prof Lorentz's presentation that is rather puzzling On p 17, and again on p 27, he strongly maintains that the contraction of a moving rod is a real effect, and not merely apparent This seems to be in direct conflict with the opinion of Eddington (cf "The Mathematical Theory of Relativity", p 26) On p 28, Prof Lorentz supports his view by saying that the contraction can be photographed This perhaps establishes it as a real effect of the relative motion between the rod and the camera, but scarcely as a real property of the rod itself H T H P

Probability and its Engineering Uses By Dr Thornton C Fry Pp xiv + 476 (London Macmillan and Co, Ltd, 1928) 30s net

UNDER the impact of numerous scientific developments, physical, biological, and engineering, the subject of probability is gradually finding a position of first importance among mathematical studies Beset as it has been with its own natural difficulties and with the conflict of views regarding its foundations held by various sections, no authoritative treatise has so far appeared that has been accepted without question by all sides Many text books on the subject in the past have at best been a mere collection of examples with little or no co ordination The present volume is the result of a course given at the Bell Telephone Company and at the Massachusetts Institute of Technology on the theory of probability as applied to electrical problems, in particular those problems that arise in the work of the telephone exchange Although the book bears clear evidence of its origin, its utility is not in any sense limited to this field, and its applications in numerous directions are to real and useful things

The introductory chapters contain a very sound exposition of the fundamentals of the subject, and the author is at great pains to bring out the circumstances in which the purely abstracted problem of probability may or may not be expected to have its application in the real world In later sections, averages and distribution functions, as they occur most frequently in engineering statistics, physics and actuarial science, are handled with interesting and detailed discussions on traffic density and adjustment of traffic flow, especially in relation to the work of telephone exchanges For physicists a chapter of especial interest is that giving a concise treatment of the kinetic theory of gases, with the numerous applications of probability in that field clearly set out The book is at once clear, bright, readable, instructive, and accurate, and is certainly to be recommended

Vertebrate Zoology an Introduction to the Comparative Anatomy, Embryology and Evolution of Chordate Animals By G R de Beer (Text Books of Animal Biology) Pp xx + 505 (London Sidgwick and Jackson, Ltd, 1928) 15s net

A NUMBER of topics of considerable interest in comparative anatomy and embryology have been dealt with in the researches of recent years, but, despite their importance, they have been slow in finding their way into text books, particularly in the English language The present volume is largely concerned with these, although more generally available conclusions of fundamental importance are also included They are discussed clearly in a series of separate chapters, some of which might be expanded with advantage, and occupy just over a third of the book

The chapters on the embryology of *Amphioxus*, the frog, the chick, and the rabbit as illustrating different types of development, and those on the evolution of the various classes of chordates, are written in an interesting manner The early chapters, giving descriptions of nine different forms, are very brief and will not be of much service to the student although they may help the layman to appreciate the discussions in the subsequent pages Some of the illustrations are not up to the standard that might be expected in a work of this description, and here and there are statements that are ambiguous or incorrect

The book furnishes the general reader with a good review of the present ideas in chordate morphology, and the student of zoology will also find much that is of interest and use to him in his studies

A Study in Tubercle Virus, Polymorphism, and the Treatment of Tuberculosis and Lupus with Oleum allii By Dr William C Minchin Third edition Pp xvi + 110 + 26 plates (London Baillière, Tindall and Cox, 1927) 25s net

THE main thesis of this book is that the bacillar one is not the only form of the tubercle bacillus, and that minute spherical granules are extruded from the bacillus, which undergo a cycle of development consisting of division, budding, and protrusion of tubular structures As regards the granules, the author's observations are probably correct and are confirmatory of those of Spengler, Much, and others, and of the more recent work which suggests that there is a 'filterable' stage of the tubercle bacillus The development cycle seems much more problematical and needs confirmation For the treatment of tuberculous conditions, the author extols an old remedy, oil of garlic, and produces sufficient evidence of its clinical value to suggest that it is worthy of more extended trial The book is illustrated with a number of excellent plates, though it is questionable if the high magnification (×4000 5000) employed in the photomicrographs is of much value, as resolution is not increased thereby and there is some loss in definition

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Distribution of Temperature in the First 25 Kilometres over the Earth

IT is with much pleasure that I notice in NATURE of June 1, p 834, Dr Ramanathan's amplification and correction of the tropical portion of my diagram of distribution of temperature in a vertical section of the atmosphere of the globe from the summer pole to the winter pole I hope the time is not far distant when some other enterprising meteorologist will render a like service for the polar regions of that diagram It is badly needed

While, however, we are waiting for that amplification, it would be very helpful if Dr Ramanathan would supplement his contribution by additions and corrections within his knowledge to another diagram, namely, that of lines of equal entropy in a similar section which will be found on p 116 of the volume to which he refers

My reason for asking for this particular service is that, in order to deal with the physics of the upper air, the distribution of temperature alone is not sufficient, the corresponding values of pressure come into consideration too, and the best form in which the information about pressure can be conveyed is by a corresponding diagram of isentropic lines which can indeed be superposed without risk of confusion upon the isothermal lines already drawn

In explanation let me say that everybody recognises that convection is a primary feature of weather, and we are accustomed to think of temperature enhanced beyond that of the environment as the natural preliminary to convection So it is, but it is temperature in relation to pressure—entropy, in fact—that really counts It is entropy which decides the equilibrium position of a sample of air, whether it will rise or sink or stop where it is in a particular environment Entropy depends on temperature and pressure It is reduced by reduction of temperature, but enhanced by reduction of pressure in accordance with algebraical formulæ which are quite easy to work, and are set out in the report of the recent Leipzig meeting of the International Commission for the Exploration of the Upper Air The physical significance of an isentropic surface in the atmosphere is that air cannot pass upward from it without access to a supply of heat, nor downward without getting rid of heat Circulation along an isentropic surface on the other hand can take place without any communication of heat, no matter whether the controlling surface be horizontal or vertical at the position of the sample Convective equilibrium is the name which our predecessors gave to an isentropic condition in the vertical, and no energy is required for motion where there is convective equilibrium We are accustomed to think of convective equilibrium as characteristic of a considerable horizontal area, but that can scarcely be so—differences arise from variations in surface temperature, height, or solarisation, and the minutest difference in a region of convective equilibrium is dynamically operative

Hence the lines of equal entropy in a vertical section are a guide to the conditions of the circulation of air and may be regarded as essential to the comprehension of the physics of the atmosphere

Doubtless, in order to deal with particular conditions, diagrams of isentropic surfaces for the particular occasions are necessary, and they can be provided as soon as we can get maps of the distribution of pressure and temperature at successive levels The diagram of normals is not the final step, but it is at least a first stage, and an important one in the prosecution of productive inquiry, I trust that Dr Ramanathan will find an opportunity for providing it Personally, I require the information for tracing possible tracks of air elevated by convection in the tropical regions and descending somewhere else I have a place ready for it, and if he will supply it I shall be correspondingly grateful NAPIER SHAW

An Ancient Spearhead

IN the British, London, and Aylesbury Museums are a few iron spearheads, presumably of the Early Iron Age, and evidently copied from the cast bronze spearheads of the late Bronze Age, which ended about 800 B C in Britain All of these were found in England Mr Reginald A Smith, Keeper of British and Medieval Antiquities, British Museum, informs me that their occurrence has long been a mystery, that, on one hand, it is difficult to account for their

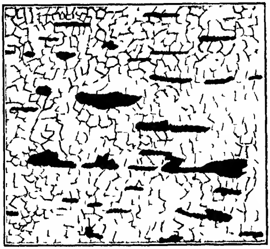

FIG 1

shape in wrought iron by reason of the high degree of technical skill required for their manufacture in this way, and that, on the other hand, cast iron, of which they may possibly be composed, is supposed to have been unknown even in medieval times

I was recently approached by him to know whether it would be possible to put this matter to the test, and a specimen in the British Museum from Golden Lane, City of London, was selected for this purpose, The weapon in question is a narrow leaf shaped spearhead of Bronze Age type, 7½ inches in length, having a short round socket with flattened sides which are pierced by two holes for a rivet The blade has a mid rib extending to the tip, and inside the socket tapers for a length of 5¼ inches Its approximate date is 7th century B C It may be a century or two later, but scarcely earlier

There was no difficulty about preparing a surface suitable for microscopic examination, although owing to the regulations the specimen itself could not be taken out of the Museum, and the necessary work had to be done there For this reason it was not

possible to photograph the actual structure obtained The section examined was parallel to the surface of the spearhead and about half way between the tip and the broadest point A sketch of the microstructure was made with great care by my assistant, Dr J M Robertson, and from this the accompanying photograph (Fig 1) was prepared The structure shown is at a magnification of 120 diameters It is typical of wrought iron The black elongated areas with somewhat serrated and rough edges represent the slag threads which have been elongated in the direction of working The small irregularly shaped polyhedra are the crystals of iron There is no doubt, therefore, that this particular spearhead consists of wrought iron, and not of cast iron

Without a complete examination and consequent destruction of the spearhead, it is impossible to ascertain how the forging was done, but there are certain features of the specimen itself which suggest two possible methods of forming The hollow centre of the rib extends to within a short distance of the point of the spear and tapers with the rib so that the metal of the rib is of approximately the same thickness throughout its length It would appear that this hollow in the rib is a consequence rather than an object of the method of forging, and it indicates that the forming was carried out on a mandril of metal or stone Two alternative methods of forming may be considered In the first the spear head could have been made from a long strip bent back over the mandril and forged down at a welding heat In this way the head would be formed from one piece of metal, the leaf shape would be obtained by chipping or grinding, the joints would correspond with the edge of the spear and a mandril would be necessary to form the central rib In the second, the mandril may have been used to pierce a billet of suitable size and have served as a means of holding the metal during forging and as an aid in forming the rib

Whatever method of forging was in fact adopted, the crystal structure of this spearhead is very similar to that of a wrought iron produced at the present time It is impossible not to admire the skill of the earliest iron workers who produced results such as this

The Dehydration of Benzene

PROF H B BAKER has shown that prolonged contact between benzene and phosphorus pentoxide results in a marked rise in the boiling point of the liquid From this we may safely infer that corresponding and concurrent variations in other physical properties, such as the refractivity, freezing point, and specific volume, take place during the process of dehydration

To test the accuracy of this supposition, I have during the past year carried out many determinations of the refractivity of benzene in the presence of pure phosphorus pentoxide For this purpose use was made of (a) a hollow prism and refractometer readable to 1" of arc, and (b) a Jamin interferometer by Hilger capable of measuring to within $\frac{1}{4}$th of a fringe For each series of experiments the benzene bought as 'pure' was re purified and subjected to a preliminary drying by calcium chloride

After introducing the benzene into the prism or interferometer, a first determination of the refractivity was made Pure phosphorus pentoxide was then placed in the liquid, and additional and periodic measurements of the refractivity effected Data thus obtained during an interval approximating six months, proved that as a result of exposing the benzene to the action of the dehydrating reagent the refractivity changed continuously On plotting refractivities against time, the resultant graph consisted of two distinct portions or limbs, both smooth, but having very different directional values A study of the whole graph has led to the conclusion that the first limb represents the rate of the removal of the mechanically admixed water, and that the second limb offers a measure of the rate of the withdrawal of water in actual combination with benzene In other words, the first limb of the graph is indicative of the rate of drying as ordinarily understood, and the second the rate of true dehydration Whence it appears that during my experiments the benzene under observation behaved as does a wet crystallised salt, such as copper sulphate when exposed to air

The results so far obtained clearly indicate that, within some as yet undetermined range of temperature, benzene firmly combines with water, and thus forms one or more hydrates This conclusion is strengthened in consequence of some preliminary measurements of the specific volume of benzene in the presence of phosphorus pentoxide This physical 'constant' is found to be dependent upon the temperature to which the benzene has been exposed *immediately before* the determination is carried out For example, I find that the normal specific volume at 18° C is lessened by a preliminary cooling of the benzene in melting ice, and increased when the liquid is first heated to 21° C Whence it appears, first, that during crystallisation, combined water is ejected from the benzene and taken up by the phosphorus pentoxide, and secondly, as the temperature is raised from 0° to 21° C, the process of dehydration is reversed so that the benzene is re hydrated by the withdrawal of water from the newly formed metaphosphoric acid From this it follows that the drying power of anhydrous benzene is, within certain limits of temperature, greater than that of phosphorus pentoxide

During precisely similar experiments conducted with benzene in the absence of phosphorus pentoxide, the changes in the specific volume, although in kind the same, were relatively quite insignificant

These investigations are being extended, and in due time I hope to give a detailed account of the work elsewhere

The Intensive Drying of Liquids

THE well known work of Prof H B Baker on the properties of liquids and solids which have stood for long periods of time in closed vessels with phosphorus pentoxide is of the greatest importance to chemists Since the publication of Prof Baker's 1922 paper, in which he reported a remarkable change in some of the physical properties of ten liquids which had been dried for from eight and one half to twenty eight years with phosphorus pentoxide, the problem of the influence of traces of water on pure chemical substances has been of controversial interest Several authors have described experiments which are interpreted as confirming Prof Baker's work (Smits, *J Chem Soc*, **125**, 1068, 1924 Mali, *Z anorg Chem*, **149**, 150, 1925 J W Smith, *J Chem Soc*, 867, 1928), while I have not been able to check this work (Lenher and Daniels, *Proc Nat Acad*, **14**, 606, 1928) with benzene and carbon tetrachloride which had been dried for from four to four and one half years (1923–1928) The difficulties of repeating Prof Baker's experiments are very great, because

experiments carried out in a drying time less than that taken by him, which do not effect a change in the dried liquids, can always be met with the practically unanswerable criticism that intensive drying had not been obtained

I have no reason to believe that the liquids described by me in the *Proceedings of the National Academy of Sciences* were not intensively dried In fact, if one accepts the work of Smits (loc cit) the liquids which were sealed up with phosphorus pentoxide in 1923, and were examined in 1928 by me, were certainly intensively dried, though no change in the physical properties of these liquids was observed As I could see no explanation of my results other than the obvious conclusion that the boiling point of dried liquids and undried liquids is the same when superheating is effectively prevented, there remained the difficulty of explaining Prof Baker's remarkable results Experiments were performed to see if the effects reported by him could not be obtained under similar experimental conditions with ordinary liquids These experiments, a full description of which will be published shortly in America, show that ordinary pure benzene carbon tetrachloride, and water give apparent boiling points as high as 27° above the normal boiling point when measurements are carried out in a reproduction of the apparatus described by Prof Baker and Prof Smits I have repeated the crucial experiment of Baker and Smits (Smits, loc cit , Baker, *J Chem Soc*, **123**, 1223, 1923) with exactly the apparatus and procedure described by them, using ordinary benzene, and I have observed the same phenomena There can be no doubt that what is interpreted by these authors as a fractional distillation of dried benzene is superheating of benzene, for the same effect is obtained with ordinary pure benzene

The conditions which are favourable to this apparent rise in boiling point have been studied and will be described at length elsewhere Some of these conditions are (1) the use of a heating bath (2) the immersion of the thermometer bulb in the liquid the boiling point of which is being measured (3) allowing a liquid to stand in contact with a flocculent solid, such as redistilled phosphorus pentoxide, which will remove dust particles (Spring, *Rec Trav Chim Pays Bas*, **18**, 233, 1899), and (4) distillation of the liquid into a clean flask before determining the boiling point, which tends to free the liquid of dust particles which act as centres for the formation of bubbles to initiate boiling (Martin, *J Phys Chem*, **24**, 478, 1920)

I have repeated and extended Prof Baker's experiments on benzene which has been subjected to a high direct current potential (*J Chem Soc*, 1054, 1928) The boiling point of benzene subjected to a potential of 450 volts direct current for more than twenty four hours in a reproduction of Prof Baker's apparatus was found to be unchanged, namely, 80° to 80 2°, when heating was carried out with a platinum wire heating element under conditions where it is known there is less than 0 03° of superheating When boiling point determinations were carried out both on benzene subjected to the direct current potential and ordinary benzene with no potential applied in an identical apparatus, using a heating bath (Prof Baker seems to use a heating bath in his boiling point determinations), no difference which could be attributed to the influence of the potential was observed, both tubes were easily heated 10° to 25° above the boiling point of benzene before ebullition began One is forced to conclude not only that there is no real change in the state of liquids subjected to a high direct current potential, but also that the original measurements were carried out under conditions where superheating is practically unavoidable

It does not seem necessary here to consider the theories of Prof Baker and Prof Smits on the intensive drying of substances, but this matter, together with additional experiments and a review of the published evidence for the change of some of the physical properties of liquids on prolonged drying, will be dealt with in the forthcoming paper referred to above

X-ray Evidence for Intermolecular Forces in Liquids

DIFFERENT mathematical methods[1-5] have been used to express the conception of the 'structure of a liquid' in exact formulæ, mainly with the intention of accounting for the X ray diffraction pattern The different treatments, however, have a common principle, which for our purpose may be stated in the following way The arrangement of the molecules in the liquid, and of the electrons in the molecules, causes a non uniform distribution of scattering power in the liquid This distribution may be resolved in a continuous range of periods in a way analogous to, but not identical with, ordinary Fourier analysis In X ray terminology these periods may be called 'spacings', if properly defined each of them is related to a certain diffraction angle by the well known Bragg relation, and their strength is measured by the corresponding intensity in the diffraction pattern

We will confine ourselves to molecules which do not differ *very* much in shape from spheres Then the most prominent spacing is due to the mutual distance of neighbouring molecules, and it is indeed this spacing which accounts in most cases for the 'principal halo', as has been put on firm ground for the first time by an experimental study of Keesom[1]

The interpretation of the diffraction pattern *outside* the principal halo is complicated by the fact that here the 'inner structure' of the molecule, mentioned above, may also play a part On the contrary, I wish to emphasise that this influence must be negligible in the region of the pattern *inside* the principal halo This arises from the fact that if the inner structure is resolved into 'spacings', these are of course mainly shorter than the intermolecular distances Therefore it may be stated that *the diffraction pattern of liquids inside the principal halo is only related to the mutual arrangement of the molecules*

This circumstance suggests the possibility of applying some theoretical considerations First, it has been shown[3,4] that for the case of *very* small diffraction angles the intensity must approach a definite limiting value, which may be calculated from the compressibility of the liquid, and is ordinarily about five per cent or less of the intensity that would result if the scattering of all molecules were incoherent But we may perhaps go a little further, at least when the intermolecular forces may be neglected (except of course in so far as they prescribe a definite volume for a definite quantity of molecules) To this end we compare our problem with the analogous one-dimensional case,[4] where the required calculations are easily carried out rigorously, and show that, when we proceed

[1] W H Keesom and J de Smedt, *Proc Amsterdam*, **25**, 188, 1922 W H Keesom, *Proc Amsterdam*, **30**, 341, 1927

[4] F Zernike und J A Prins, *Zeitschr f Phys*, **41**, 184, 1927

[5] G W Stewart, *Phys Rev*, **32**, 558 1928

from the principal maximum to smaller angles the intensity falls off continuously and rather rapidly to the limiting value already mentioned There is no reason to suppose that this should be radically different in three dimensions

With the view of testing these points I have recently examined the diffraction pattern of many liquids at small diffraction angles and have arrived at some results that seem interesting enough to communicate to NATURE As an example let us take water (here it is chiefly the arrangement of the oxygen atoms that determines the diffraction pattern) It is well known that the principal halo of water lies at a diffraction angle to which corresponds a spacing of about 3 A, in good agreement with the mean intermolecular distance I have found however that at the inner side of this halo the intensity is rather strong and roughly constant till a very small angle is reached, corresponding to a spacing of about 17 A At this angle the intensity falls off rapidly, and for still smaller angles approaches a limiting value which may be assumed with some reason to agree with the theoretical limiting value considered above But how are the spacings between 3 and 17 A to be explained? We have already seen that we certainly must look for an explanation in the arrangement of the molecules A closer examination shows that this arrangement must be of the following kind in the immediate neighbourhood of every molecule the mean density must be greater than at greater distances This arrangement may be described as a 'tendency to association' though I think this is mostly to be understood in a dynamical rather than in a statical sense The reason of this arrangement is, of course, to be found in the nature of the attractive intermolecular forces

The same strong scattering inside the principal halo is found with many other liquids, and recently it has also been remarked by Krishnamurti [6] that with liquids classified from other reasons as 'associating' it is often so strong as to give rise to an 'inner ring' This agrees with the explanation given above

I should like, however, to point out, that a scattering inside the principal halo, stronger than the limiting value, though much weaker than in the previous cases, is present also with liquids, as benzene, carbon tetrachloride, carbon bisulfide, and others,[7] which are usually not called 'associating' Indeed the only exception known to me is that of mercury From this it would seem that in the X ray pattern we have a much more sensitive method for studying the intermolecular forces than in many other methods Perhaps we may hope in due time to be able to draw more definite conclusions from it In this respect it might even sometimes serve us better than the diffraction pattern of the solid state

X-ray Pattern of Metallic Crystals

WHILE reading the literature on diffraction of X rays, I came across interesting photographs of X ray patterns for a few metallic foils—aluminium, cadmium, copper, lead, silver, thallium, tin, zinc, and several kinds of brass—at different temperatures (Nishikawa and G Asahara, *Phys Rev*, 1920) The most interesting fact one finds from this paper is that there is a remarkable change in the nature of the pattern for a metal as time elapses after the rolling process Silver and tin for example gave ill defined patterns immediately after the rolling process, but these gradually changed during the following two or three weeks to the distinct spot patterns characteristic of annealed samples Nishikawa and Asahara conclude from this that for these samples the crystal growth which accompanies anneal ing takes place at room temperatures

We had in our laboratory a few metal foils kept at room temperature for about twenty years This is indeed a sufficient time for the complete recovery of the foils after the process of their production, and a beautiful spot pattern was expected Patterns for a few metallic foils were therefore taken For this purpose a Hadding tube with a copper anticathode was worked at about 85 kv and 10 ma A strong beam of X rays was allowed to pass through the material The pattern was recorded on a photographic plate kept at a distance of 3 cm from the leaf Silver and gold gave a ring pattern the rings were quite continuous and there was no indication of any spots on the plate In the case of tin (grey) the pattern was mostly similar to No 27 of Plate 1 of the paper quoted above and not spots as in No 27 For gold and silver the rings were not only of similar nature but were also of identical diameter The diameter of the inner ring was 3 7 cm, and that of the outer one 4 5 cm The intensity of the inner ring was about ten times the intensity of the outer one From these facts one is tempted to draw the following conclusions

(*a*) For silver and gold the lattice is the same, and is the same in magnitude This is borne out by the experiments made by 1 Vegard in a different way (*Phil Mag*, 32, 1920) (*b*) These metals do not recover from the effects of the process by which the leaves are made using the terminology of Nishikawa and Asahara (*c*) It is more proper to regard a thin metal leaf as an assemblage of metallic crystals as in the case of powders, for which by Hull's method we always get a ring pattern

Taking d as the lattice constant responsible for the production of both the rings, we find that $\sin\theta/\sin\theta = 0\ 87$, which is about the same as $Cu(K\beta)/Cu(K\alpha)$ It thus appears that the two rings are due to $K\beta$ and $K\alpha$ lines of copper

Emission Lines in the Spectrum of the Solar Corona

IT seems very improbable that the bright line spectrum of the inner corona can be attributed to thermal excitation of the coronal matter We may seek its cause in the process of photoelectric ionisation and apply then, as a first and rough estimate of its brightness, the same analysis as Dr Zanstra has done in the case of diffuse nebulæ (*Astrophys Jour*, 65, No 1) Thus we assume in this approximation that the emission spectrum of the corona is due to a mechanism of recombination of free electrons with atoms, ionised by the high quantum radiation, emerging from the sun, acting as a black body radiator, and that the corona consists only of monoatomic hydrogen We have to suppose, further, that the high quantum radiation is completely absorbed by the coronal material, and that all the freed electrons recombine with the ionised hydrogen atoms

[6] P Krishnamurti, *Ind Jour Phys* Calcutta 2, 491 1928 In another paper Mr Krishnamurti has also studied solutions from the same point of view as I did in a previous letter to NATURE (*Ind Jour Phys*, Calcutta, 3, 209, 1928, NATURE 123, 84, 1929)

[7] As a curious fact it may be mentioned that organic iodides seem to show an inner ring while bromides do not, even if the molecules are rather long (for example, C_{16}-dibromide) For the longest spacing of C_{16}-dibromide in solid state I found 12 6 A, this low value probably indicates that the CH_2-chain is not straight in this compound

With these assumptions we can apply Zanstra's formula for the ratio of the integral brightness of the corona to that of the sun

$$L \sim \int_{x_0}^{\infty} \frac{x^2}{e^x - 1} dx \Big/ \int_{x_1}^{x_2} \frac{x^2}{e^x - 1} dx, \quad x = \frac{h\nu}{kT},$$

where T is the sun's effective temperature, h and k are well known constants ν_0 will be in our case the frequency corresponding to the head of the Lyman series ($32\ 84 \times 10^{14}$), ν_1 and ν_2 are the limits of frequency for photographic rays ($\nu_1 = 5\ 95 \times 10^{14}$ and $\nu_2 = 9\ 10 \times 10^{14}$) Expressing L in differences of stellar magnitudes Δm we get

T	Δm	m
6400	18 0	8 0
6200	99 1	6 9
6000	20 0	- 6 0
5800	20 8	- 5 2

(m_c is stellar magnitude of the corona, $m = -26\ 0$ mag)

We can conclude from these data that even in the case of lowest admissible effective sun's temperature, we should obtain on the plates the effect of a relatively faint but characteristic bright line spectrum superposed on the continuous spectrum of the corona (Russell Dugan, Stewart, Astronomy, vol 2, p 507)

It should be noted that the proposed explanation of the bright coronal lines is related to a fact noticed by Balanovsky and Perepelkin (*Mon Not Roy Ast Soc*, **88**, p 747), namely, that the coronal material seems to be attracted by the solar prominences This may be due to the fact that a part of the high frequency quanta, being absorbed by the prominence, does not reach the coronal matter and produces a darkening of the corona over the prominences In that case the coronal emission lines ought to weaken considerably above a prominence, and such an effect, if observed during an eclipse, would afford a proof of the photoelectric origin of the coronal emission spectrum

Growth-gradients and the Axial Relations of the Body

IN previous communications (see Huxley, 1927, *Biol Zentralbl*, **47**, 151) it has been pointed out that in Crustacea the presence of a centre of active growth, for example, in a male chela, is associated with excess growth of the other walking legs The third maxilliped, however, is not affected in this way, but appears to be slightly decreased in the male The question arose whether this was a positional effect, appendages anterior to the growth centre being inhibited in their growth those posterior being accelerated, or whether, since the maxilliped was an appendage of different type from the pereiopods, its growth was not correlated with theirs

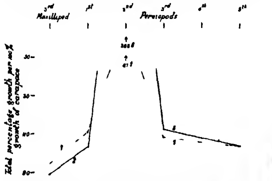

FIG 1—Amount of growth in length per 100 per cent growth of carapace length in male and female prawns (*Palæmon carcinus*)

To settle this question, measurements have been made on a large Indian species of *Palæmon* (*P carcinus*) in which the second pereiopod, not the first, is enlarged as the male chela The material was presented by the Zoological Survey of India through the kindness of Col Seymour Sewell

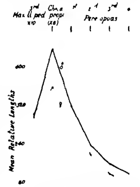

FIG 2 Relative lengths (in per cent of carapace length) of male and female spider crabs (*Inachus dorsettensis*) After M E Shaw *Brit Jour Exper Biol* **6**, 145

The results appear quite definite For 100 per cent increase in carapace length the percentage increase in length of the various limbs measured are as follows

Maxilliped	Pereiopod				
3rd	1st	2nd	3rd	4th	5th
♂ 89 0	103 2	265 0	112 2	107 8	103 2
♀ 94 6	111 1	167 0	108 1	105 2	103 1

The accompanying diagram (Fig 1) shows the results graphically Fig 2 shows the effect in *Inachus*, where the first pereiopod is the large chela Other methods of analysing the figures confirm this conclusion, namely, that exceptionally active growth in one appendage is correlated with a slight acceleration of growth in the appendages posterior to it, a slight retardation in those anterior

It has previously been established that the heterogonic growth of an appendage takes place most rapidly in a 'growth centre' near its tip, and that there is a 'growth gradient' down from this region towards the trunk It would thus appear that when the local growth gradient of the appendage reaches the trunk, it is influenced by the axial relations of the whole animal, and affects the regions posterior to the appendage in a different way from those anterior to it No view has as yet been put forward as to the mechanism of this influence, and we should welcome any suggestions bearing upon it

Growth and Longevity of Whales

ACCORDING to Mr N A Macintosh (British Association Report, 1928) Blue whales and Fin whales grow quickly and probably reach maturity in the short space of two years, Mr Macintosh's statement implies that, in favourable circumstances, these great animals might increase in number fairly quickly, but that they die without attaining any great age

In the case of the Greenland whale the duration of gestation and lactation are unknown, but the following facts suggest that it takes more than two years to reach maturity, that it multiplies very slowly, but that it attains a considerable age

1 So far as can be ascertained now, the Greenland

whale is 14 or 15 feet long at birth, is about 20 feet long and its whale bone less than 2 feet long when it is weaned, but is not sexually mature until its length is about 50 feet and its whale bone exceeds 10 feet.

2. As stated in my letter on the "Extermination of Whales" (NATURE, Mar. 2) in the Greenland Sea in the period 1860–1909, only a small number were killed by the whalers, including those that may have died after breaking loose, two or three less than ten a year, and that notwithstanding this small mortality at the hands of their human enemies in those years they showed no signs of increase. It might be objected that the whalers were not the only enemies of the Greenland whale and that others came to an untimely end in other ways, but of this there is no evidence. In the Greenland Sea the Killer whale, its most likely enemy, is not found amongst the ice, and as far as I saw the whales do not appear to suffer or die from disease. Only those that died from harpoon wounds were found floating dead.

3. Harpoons were sometimes found in whales, which the animals appear to have carried about buried in them for a long time.

In the Greenland Sea, in 1863, my father killed a large whale in which he found an old harpoon marked 'Pow and Fawcus, Newcastle, 1839', and in 1872 he killed two others, also large, in each of which he found old harpoons (Buckland's "Log book of a Fisherman", etc., p. 247).

In Davis Strait in 1894 the *Terra Nova* killed a large whale (12 feet bone), in the blubber of which was found embedded a harpoon bearing the name 'Jean of Bo'ness', and dated forty years back. The *Jean*—a well known whaling ship—was lost in Davis Strait in 1857 (*Zoologist*, 1895, p. 94).

Reduced Flowers of *Ranunculus*

I AM glad my letter to NATURE (April 13, p. 568) has been the means of eliciting from Mr. Marsden Jones and Dr. Turrill a very interesting joint communication (NATURE, May 25, p. 798) on the above subject. I hope I have not unwittingly been attempting to steal their thunder!

The references to the literature they give are very welcome. Apparently these buttercup plants with reduced (female) flowers have hitherto failed to interest British field botanists—an instance perhaps of the lack of sympathetic feeling and co-operation between the systematists and the geneticists.

As yet I have not come across in this district the reduced form of *Ranunculus bulbosus*, but shall keep my eyes open now that the buttercup season is with us. Plants of *R. acris* with the small flowers and aborted stamens are appearing as usual.

If there be evolutionary significance in these reduced flowers, then seeing there are all grades between plants with completely hermaphrodite flowers and those with no functional stamens, it looks as if there is here an example in support of the view of "the inevitability of gradualness" (to adopt a famous phrase used in another connexion) in evolution.

The writers of the joint letter express surprise at my not mentioning a freak plant of *Ranunculus acris* I found here in the middle of a pasture field a few years ago. Reference to such a plant did not appear germane to the subject matter of my former letter, for I regard it as a sport which has no bearing on the evolutionary trend of the species. Others naturally may take a different view. It is pleasing, however, to know that it is of value to these workers on the genetics of the genus, especially as they have proved it to be functionally male only—a point which was not obvious to me at the time of its discovery. The original plant is still in the garden here. It does not grow nearly as strongly as the ordinary or reduced (female) form of *Ranunculus acris*; consequently in the wild state it might soon have failed to hold its own and been squeezed out of existence. It was a frail affair when I lifted it from the pasture. A feature of it not mentioned in the Marsden-Turrill letter is the distinctive character of its foliage. The leaves are somewhat crested and less sharply cut than those of the type, so that the plant can readily be recognised when not in flower.

Nervous Impulse in *Mimosa pudica*

IN a letter under the above heading (NATURE, April 13, 1929) Prof. Hans Molisch describes certain experiments which appear to confirm the earlier work of Sir J. C. Bose. Space does not permit of a full discussion of these results, but it is rather surprising to find that Prof. Molisch regards the experiment of Bose on the supposed reflex arc as satisfactory evidence, since the fallacy in this experiment has already been demonstrated by K. Umrath (*Planta*, 5, 1928, p. 295, footnote).

As Umrath points out, and as I also have found, the serial reactions of the pinnæ take place in the same way, whether one stimulates a pinna of a leaf attached to a shoot or one from which the main pulvinus has been removed. This fact disposes of the contention that an afferent impulse is changed into an efferent one in the main pulvinus. Further, neither Sir J. C. Bose nor Prof. Molisch mentions the reactions of the secondary pulvini. I have noticed that if one stimulates one pinna, either electrically or by cutting, in the large majority of cases the secondary pulvini of the other pinnæ react *before* the main pulvinus, thus showing that the excitation has already reached them. As Umrath points out, there is a delay in the transmission between the secondary pulvinus and the basal pair of pinnules. This delay allows time for the excitation to reach the main pulvinus, which thus reacts before the excitation is apparent in the pinnules on the unstimulated secondary petioles.

Occasionally I have observed the excitation beginning to pass up the unstimulated pinnæ before the main pulvinus reacts, but usually the time which has elapsed is not sufficient for it to pass beyond the secondary pulvini.

It is therefore apparent the transition of the excitation from one pinna to another takes place at the apex of the petiole and not through a reflex arc passing through the main pulvinus.

The Ratio of the Mass of the Proton to that of the Electron

IN a recent paper (*Proc. Roy. Soc.*, 122, p. 358, 1929) Prof. A. S. Eddington reached the conclusion that the value of the physical constant $ch/2\pi e^2$ is given by the integer 136. His theory reduces the evaluation of this constant essentially to the counting up of symmetrical elements in a square array. The numbers

of such elements in arrays arising in this connexion are 10, 136, etc

In this light, it is interesting to speculate if at least some of the dissimilarities between the proton and the electron are not somehow bound up with the question of degrees of freedom, and, in particular, if another important non dimensional physical constant, namely, the ratio of the mass of the proton to that of the electron, M/m, cannot be accounted for by counting up elements and by performing simple operations with the numbers so obtained If so, it is plausible to assume that M/m should depend on two such numbers, one of them being 136 The other number here taken is 10, as the absence of protonic spin hints at the smaller value With these two integers on hand, and with the observed value of M/m (1840, roughly) in mind, it is tempting to write

$$\frac{M}{m} = \frac{(136)^2}{10} = 1849\ 6$$

I am aware of no proof of this relation But as I do not, at present know of any reason for ascribing the numerical result, without at least some hesitation, to a mere coincidence, I believe that the numerical agreement in this empirical relation warrants notice

Freshwater Medusæ in England

IN NATURE for Jan 12, Prof Hickson has recorded freshwater medusæ and their polyps from Mr V B Poulton's aquarium at Boscombe Afterwards these were assigned to *Craspedacusta sowerbii* after comparison with drawings made at the British Museum of polyp stages of that species found last summer on *Pandanus* roots in the *Victoria regia* tank of the Royal Botanic Society and exhibited at a meeting of the Zoological Society

The Boscombe polyps afford additional confirmation of the evidence for linking Sir Ray Lankester's Regent's Park medusa with the polyps of Bourne, Parsons, and Fowler, since they bear medusa buds

In case any other amateur should observe freshwater medusæ in England it is to be hoped that it will occur to him to communicate with the British Museum It seems highly probable that *Craspedacusta* occurs in a wild state in British river systems, and it would be well if a sharp look out for it were maintained

The Crystal Structure of Nickel Films

FILMS of nickel deposited on rock salt by sputtering in residual gas or argon, show an unexpected structure on removal from the rocksalt and examination by the cathode ray diffraction method As is well known, the normal structure of nickel is face centred cubic, as found both by X-ray and electron diffraction methods The new structure turns out to be hexagonal, the values of the axes being $c = 4\ 06$ A , $a = 2\ 474$ A ratio 1 64, which is near enough to the ratio 1 633 for closest packing Nickel thus resembles cobalt in crystallising in both cubic and hexagonal closest packing The density calculated from the above axes is 8 86, in good agreement with that of the metal in bulk The structure is thus different from an hexagonal form found by Bredig and Allolio (*Zeit f Phys Chem* , **126**, p 53, 1927) by spluttering in hydrogen The latter had a density of only 7 04 and is probably a hydride The above is, I believe, the first case of a new crystal form found by electron diffraction

A Proposed Survey of the Burnet-moths

I AM at present undertaking a survey of the variations in the male and female genitalia and in the wing patterns in the genus *Zygæna*, or Burnet moths This necessitates the collection of specimens from as many parts as possible of the British Isles and continent of Europe I should therefore be very grateful if specimens could be sent to me this summer They should be taken *in pupa* and, if possible at least two dozen from one locality or colony It is very necessary that pupæ from neighbouring or different colonies should be kept separate Details as to the position and extent of the colonies would be welcome so that they can be identified afterwards on Survey maps Pupæ may be taken on the grass stems, packed in a small box and sent to the address below Due acknowledgments to the collectors will be made of course in resulting publications

The Emission of Positive Ions from Metals

DURING the study by me of critical potentials in metallic vapours (*Phys Rev* , August 1928), it was noticed that positive ions were given off by heated metals and that these ions persisted for very long periods of heat treatment A determination of e/m of the positive ions from heated metals gives the following results Copper, iron, nickel, and platinum when heated, give alkaline ions only, as has been found by other observers Tungsten, molybdenum, and tantalum when heated to a temperature where vaporisation becomes appreciable, give ions the atomic weights of which agree with that of the metal emitting them Other metals are under investigation

Adder or Nether

IN his note upon dragonflies in NATURE of June 1, Dr Tillyard asks whether the adder is still called the 'ether' in any part of England I cannot answer for England, but 'nether' is good Lowland Scots for 'adder', and is given in that sense in Jamieson's "Dictionary of the Scottish Language" Among examples given by Skeat of initial *n* shifting from the noun to the indefinite article, or from the article to the noun, he mentions *addere* and *naddere* as interchangeable forms in Middle English , but he says nothing on the question whether 'adder' comes from Anglo Saxon neoðera, nether—the lowly one

HERBERT MAXWELL.

Monreith, Wigtownshire

The Hormones of the Sexual Glands.

RECENT work on the internal secretions of the gonads illustrates the fact that progress is only rapid when a simple specific test for the principle under investigation is available The earlier reports of the isolation of an ovarian hormone failed to arouse the interest of more than a few workers, since the test of activity used, the growth of the female genital tract following injection of the extract into an immature or adult normal animal, was liable to the fallacy that such growth might have occurred naturally, whilst even in spayed animals the end point of the reaction was indefinite in either case the test animal must be killed

The discovery by Stockard and Papanicolaou that the particular stage of the œstrous cycle in a living guinea pig could be easily determined by taking a smear of the vaginal contents was soon applied by Long and Evans and by Allen to the rat and mouse, and the method of following the activity of ovarian extracts by observing the appearance of œstrus after injection of the preparation under test in ovariectomised animals by means of the vaginal smear technique was quickly developed In the case of testicular extracts no such simple test is available, with the result that our knowledge of the hormones of the ovary, incomplete though it is, is in a much more advanced state than that of the secretions of the testis

THE OVARY

A very good review of the physiology of ovarian activity has been given by A S Parkes (*Biol Reviews*, vol 3, p 208, 1928), to which those interested in this subject may be referred At the present time opinion generally favours the view that the ovary secretes at least three different hormones, one controls the development of the secondary sex organs, the uterus, vagina, etc, before puberty, one is responsible for the œstrous symptoms, whilst the third is secreted by the cells of the corpus luteum

It is possible that the prepubertal growth of the secondary organs is due to the secretion of the œstrus producing hormone, a view, however, which presupposes an abrupt change in its mode of action at puberty On the other hand, the œstrous reaction of ovariectomised animals following an injection of 'œstrin' appears incomplete, in that copulation is only infrequently observed, and in the spayed bitch the hormone only produces symptoms of pro œstrus, so that possibly the missing factor may be the hormone responsible for the initial development of the accessory sex organs The cause of the first œstrus at puberty appears to lie outside the ovary, and recent work suggests that a hormone from the anterior lobe of the pituitary gland is concerned both in stimulating the first œstrus and maintaining the regularity of the œstrous cycle However, since injection of an extract of a young male pituitary will produce œstrus in an immature female with intact ovaries, the actual reason for the sudden development of œstrus at puberty still remains obscure

By far the greater amount of recent work has been devoted to the extraction and physiology of the œstrus producing hormone or 'œstrin,' as Parkes and Bellerby have named it At present two widely different methods of extraction have been utilised, resulting in the production of the hormone in an oil soluble or water soluble state In the first method fat solvents are used for the extraction thus the minced ovaries may be thoroughly extracted with alcohol, the filtrates concentrated to a small bulk again taken up in alcohol, filtered, and set aside for the separation of fats and cholesterol The filtrate is then taken to dryness, dissolved in ether and lipoids precipitated by addition of acetone (F Dickens, E C Dodds, and S Wright, *Biochem Jour*, vol 19, p 853 1925) Material obtained by such a process is a brownish oil, soluble in fat solvents and thermostable the activity remains in solution when sterols are precipitated by digitonin A dose of about 1 10 mgm is necessary to produce œstrus in 50 per cent of a series of ovariectomised rats

A variety of methods has been used to obtain the hormone in a water soluble form Dodds has obtained it in the form of a hydrochloride by extracting minced ovaries with picric acid and acetone or minced placenta with hot hydrochloric acid and precipitating the picrate in the filtrate, the picrates being converted into hydrochlorides by solution in acid alcohol followed by precipitation of the hydrochloride by acetone the material thus obtained is of about the same activity as that extracted by the use of fat solvents More recently the same investigator has described a method for obtaining the water soluble hormone in a purer state (H Allan, F Dickens, E C Dodds, and F O Howitt, *Biochem Jour*, vol 22, p 1526, 1928) Placenta is used as source rather than ovary it is heated with baryta and the filtrate concentrated and extracted with butyl alcohol by shaking the extract is evaporated under reduced pressure almost to dryness, and the residue dissolved in hot water and filtered, the precipitate and filtrate are both extracted with ether, the extracts washed with water and concentrated to an oily residue This is dissolved in alcohol and then suspended in water and extracted with ether, the ethereal extracts are washed with hydrochloric acid and water After removal of the ether the residue is suspended in water and heated with baryta the activity passes into the filtrate from which barium is removed as sulphate or carbonate The material appears to be in true (or colloidal) solution, since it is filterable and dialysable about 0 02 mgm solid matter will produce the œstrus response on injection There is no relationship between the nitrogen content and activity of the solution Millon's reaction is positive, but the biuret test is negative

There is an important difference between the reactions of the hormone in solution in oil and in water a single dose of an oily preparation will induce œstrus in an ovariectomised rat or mouse,

whereas a single dose of an aqueous solution may be entirely without effect a series of six injections spread over forty eight hours will, however, in the case of an active solution, produce œstrus on the third or fourth day The necessity of multiple injections of aqueous solutions was first stressed by Laqueur and has been fully confirmed by Dodds

The œstrus producing hormone occurs in the follicles and stroma of the ovary but is absent from true luteal tissue it is present also in placenta, urine, and probably blood It is probably produced by the cells of the ovarian stroma, whence it finds its way to the other situations in which it is found the follicle is certainly not an essential source, since ovaries sterilised by exposure to the X ray still produce it, animals thus sterilised passing through the cyclic changes of œstrus in a perfectly normal manner As regards its presence in the placenta, it is possible that this organ withdraws it from the circulation in order to protect the fœtuses from its influence

Œstrus supervenes after an injection of œstrin in about two days, and ovariectomy may be followed by œstrus 36 48 hours later, indicating that under natural conditions the stimulus to the vaginal re action is already active about two days before the reaction occurs Examination of the ovaries indi cates that follicular maturation occurs during the 48 hours before œstrus, that is, after the stimulus has become active so that both processes appear to depend on the same stimulus, and the view that the follicle is the source of the œstrous reaction becomes untenable (F W R Brambell and A S Parkes, *Quart Jour Exp Physiol*, vol 18, p 185, 1927) Injection of a large amount of œstrin has no effect on this latent period, but prolongs the period of œstrus even up to about a fortnight Ovariectomised animals are usually fat and sluggish œstrin restores activity and reduces weight, rats show a period of maximum activity at the time of œstrus The work that has been carried out on the effect of ovarian extracts upon metabolism indicates that in some animals (dogs), especially after castration, the nitrogenous meta bolism is increased whilst the gaseous exchange is diminished injection of extracts of corpora lutea has the opposite effect on the nitrogen output In other species, for example the rabbit, little change in the metabolism has been observed following the injections (V Korenchevsky, *Brit Jour Exp Path*, vol 6, p 6, 1925) L Mirvish and L P Bosman have found that alcohol extracts of ovary reduce the blood calcium of rabbits and human beings of either sex after injection, the effect reaching a maximum in twenty four hours with a return to normal in forty eight hours (*Quart Jour Exp Physiol*, vol 18, pp 11 and 29, 1927)

The influence of the menstrual cycle upon the mental and muscular efficiency and general func tional activity of women has been investigated by S C M Sowton, C S Myers, and E M Bedale (Industrial Fatigue Research Board, Report No 45, 1928) The direction of any change in efficiency at the menstrual period appears to be influenced by the social status of the subject studied, University students showing no change or a greater efficiency As regards functional efficiency, there appears to be a periodic heightening in the late intermenstrual phase with a corresponding reduction shortly before or at the onset of menstruation Since ovulation in the human female occurs about the middle of the cycle, this result is parallel to the greater activity observed in the rat at the time of œstrus

The changes in the uterus after œstrus do not appear to depend on the presence of œstrin in fact, prolongation of the action of œstrin hinders them and injected during pregnancy, abortion is produced Although probably responsible for the pro œstrous bleeding which is seen in some animals, the post œstrous bleeding which occurs in primates appears to set in when the action of œstrin wears off Thus hæmorrhage from the genital tract has a different significance in different species F H A Marshall considers that menstruation in the human female represents a pro œstrous and a pseudo pregnant degeneration of the uterine mucosa telescoped into one phenomenon in other words, each cycle commences before the previous one has completely finished a similar overlap is observed in the cycles of the cow (*Quart Jour Exp Physiol*, vol 17, p 205, 1927)

In several species, for example the guinea pig and opossum, a certain amount of mammary develop ment occurs during œstrus and can be produced in ovariectomised animals by an injection of œstrin or by grafting an ovary into a castrated male, but such development must be distinguished from that occurring during pregnancy In general it may be stated that post œstrous changes in the secondary sex organs depend on the influence of the corpus luteum developed by the ingrowth of cells into the ruptured Graafian follicle after ovulation, the actual degree of development of this body depending on whether the ovum has been fertilised or not, and also upon the species

In the rat and mouse the development of the corpora lutea of ovulation is very slight, in the guinea pig and cow more marked, whilst in the dog, ferret, and rabbit it is so considerable that the changes brought about in the accessory organs simulate those of pregnancy A sterile copulation in the rat or mouse is followed by a more prolonged development of the corpora which become func tional Histological differences between corpora of ovulation and pregnancy have been described by A Ostrčil and O Bittmann (*Publ Facult Médicine*, Brno, vol 4, p 217, 1926)

The functions of the corpus luteum, so far as they are at present known, are four in number the inhibition of œstrus and ovulation, sensitisation of the uterus for reception of the fertilised ovum, the maintenance of pregnancy and the development of the mammary glands preliminary to lactation Removal of the corpora of ovulation in animals in which they are functional results in an earlier appearance of the next œstrus, prolongation of the functional life of these bodies causes its prolonged disappearance A single body in one ovary can pro duce this effect, and injections of extracts are stated to inhibit ovulation in rabbits (W P Kennedy

Quart Jour Exp Physiol, vol 15, p 103, 1925) Conversely, Parkes and Bellerby have found it possible to produce œstrus during lactation in mice by injection of œstrin, the amount required depending on the number of young suckling above two (when spontaneous œstrus may occur) The inhibition to the action of œstrin is abolished in a lactating mouse unilaterally sterilised by exposure of one ovary to the X ray, by removal of the opposite ovary, containing the corpora lutea, indicating that the inhibition is certainly due to a secretion from these bodies

A functioning corpus luteum is associated with a sensitiveness of the uterine mucosa to stimuli, either the fertilised ovum or an artificial stimulus, resulting in the production of decidual tissue, in which the ovum, if present, can be embedded Artificial stimulation of the mucosa is without effect in animals such as the rat or mouse with a short œstrous cycle, in which the corpora of ovulation are probably functionless, but the uterus can be made sensitive by inducing pseudo pregnancy and is also sensitive during lactation, in both of these states the life of these organs is considerably prolonged Their influence is probably hormonic in nature, since a grafted uterus can be sensitised

The presence of a functioning corpus luteum is essential for the maintenance of pregnancy, or at any rate its greater part In unilaterally sterilised mice, removal of the ovary containing the corpora invariably resulted in abortion, whilst removal of the sterile ovary was without effect hence the presence of ovarian tissue *per se* is without influence on pregnancy, the corpus luteum being the essential organ (Parkes) In the cow the corpus can be expressed manually its removal results in abortion within a few days (O Zallmann, *Publ biol Haute École Vét*, Brno, vol 1, p 255, 1922) Towards the end of pregnancy the corpora lutea atrophy, evidence has been brought forward which suggests that during pregnancy the sensitivity of the uterus towards the oxytocic principle of the posterior lobe of the pituitary gland is diminished and returns to normal when the corpora atrophy also injection of extracts, obtained from ovaries at the end of pregnancy, stimulate the secretion of this hormone, suggesting a mechanism whereby the corpus luteum both maintains pregnancy and allows parturition at the proper time

The presence of functioning corpora lutea is associated with a degree of mammary gland development which is not observed in their absence, but it is not yet certain whether this stimulus alone suffices to bring these glands to complete lactation it is possible that some product of conception is necessary for the final development E Homann has suggested that the uterus plays a part in the development of the mammary glands (*Berich Natur forsch Gesellsch Freiburg*, vol 26, p 289, 1926)

(*To be continued*)

Infra red Spectra [1]

By SIR ROBERT ROBERTSON, K B E, F R S

HISTORICAL

IN the year 1800 the elder Herschel, by placing a thermometer in the region lying beyond the visible red of the solar spectrum, gave the first experimental proof of the existence of radiation there by observing a rise in temperature of the instrument, and his son in 1840 described the existence of emission bands in the same region as shown by a discontinuous evaporation of alcohol from blackened paper placed in the same region

To illustrate action beyond the visible red of the spectrum the following experiment was made As it was impracticable to use the sun's spectrum, the beam from an arc lamp was dispersed by means of a large rock-salt prism, giving the usual spectrum visible to the eye A card on which a phosphorescent powder (calcium sulphide with nickel as impurity) was first caused to glow brightly by subjection outside the theatre to ultra violet light from a mercury lamp and then placed in the spectrum, when the existence of radiation beyond the visible was shown by the quenching of the phosphorescence for some distance past the red

This region of the spectrum attracted much interest from the middle of last century and onwards when instruments of increasingly refined character were evolved to detect and measure effects of emission and absorption of radiation there Thus photography was tried, and Abney succeeded in penetrating the region for a short distance, which has not been exceeded by more recent workers employing special sensitisers for their plates Langley with the bolometer, Boys with the radiomicrometer, and Coblentz with the thermopile, succeeded in measuring quantitatively radiation in the infra red, the last two instruments are the principal ones employed to day in that region which lies nearest to the visible Still farther out, measurement of the energy in the beam dispersed by means of reflection from the polished surface of crystals gave important results in the hands of Rubens and his colleagues, while within the last year Raman by an entirely different technique, to be mentioned later, has indicated how infra red radiations can be deduced from spectroscopic measurements in the visible spectrum

ELECTROMAGNETIC WAVES

The relationship of the infra red region to other parts of the spectrum was illustrated by a diagram simplified from that prepared by Dr F E Smith (see "Phases of Modern Science," 1925), in which the whole range of electromagnetic waves from γ rays to the longest radio waves, and only completed in recent years, is set forth On this diagram (Fig 1) were indicated the respective lengths of the waves from crest to crest in each region the cosmic rays of Millikan, supposed by him to proceed from

[1] Synopsis of the Friday evening discourse delivered on Mar 1 at the Royal Institution

the birth of atoms such as helium, oxygen, silicon, and iron, in the profound depths of space at the lowest extremes of temperature and pressure, of a wave length of about $2 \times 10^{-8}\,\mu$ ($\mu = 0\,001$ mm), the highly penetrative γ rays about $4 \times 10^{-6}\,\mu$, which accompany radioactive change, the X rays about $1\,5 \times 10^{-5}\,\mu$, also penetrative of matter on account of their short wave lengths the ultra violet rays, to about $0\,4\,\mu$, which promote many chemical reactions, the visible spectrum, from about $0\,4\,\mu$ to $0\,8\,\mu$, infra red rays, from $0\,8\,\mu$ to about $23\,\mu$ (the near infra red) or to $300\,\mu$ (the far infra red), heat rays and short Hertzian rays to $1 \times 10^{8}\,\mu$, and then the rays used for wireless, the length of which may be measured in miles, 5XX, for example, being 1560 metres or about a mile long It is a characteristic of all these waves, from the shortest to the longest, that they are propagated at the same speed, the speed of visible light, or 186,000 miles a second

The clue to the properties of these waves was found by Faraday when he discovered rotation of the plane of polarisation of light in the magnetic field, a discovery of which Tyndall said "I would liken it to the Weisshorn among mountains, high, beautiful, and alone" This in turn was translated by Clerk Maxwell into the succinct notation of mathematics, and it formed the basis of his electro magnetic theory, the foundation of modern electro mechanics Since then, the likeness in character of these electromagnetic waves has been shown by their being capable of dispersion, interference, resonance, and by many other physical properties

As to the effects of the radiations in different parts of the spectrum, it may be said that whereas in the shorter wave length regions comprising the γ, X rays, and visible spectrum, these are mostly electronic, in the infra red region the transitions are caused by changes in the oscillatory states of the atoms in the molecule or of the rotational states of the molecule itself

QUANTITATIVE MEASUREMENT OF INFRA RED BANDS

Dispersion by means of a grating having been referred to, a modern infra red spectrometer of Hilger was then described as to its respective parts, the source of radiation (a Nernst filament), the slits, the reflecting mirrors, the dispersing prism (of quartz up to $3\,\mu$, fluorite up to $8\,\mu$, of rock salt up to $17\,\mu$, or of sylvin up to $23\,\mu$), and the thermopile Special reference was made to the thermopile, composed of bismuth silver couples used in conjunction with a galvanometer for measuring the energy passing through the instrument Its sensitiveness was illustrated by allowing a little compressed air to enter a sealed bell jar containing the instrument, when by adiabatic compression of the air, the heat generated was registered by movement of a spot of light from a Moll galvanometer

An experiment was then performed to illustrate the method of mapping an absorption band, ammonia being the gas employed Two tubes were so arranged that they could alternately be thrown into the optical path between the source of radiation and the spectrometer, one tube being empty while the other contained ammonia gas The energy passing through the respective tubes was measured by a galvanometer which threw a spot of light on a large scale on the wall of the theatre At $1\,8\,\mu$ the difference between the throw of empty and gas tubes was small, but this difference increased up to $2\,2\,\mu$ and then decreased These differences were noted and then plotted against wave length on co ordinates marked out on the blackboard, when a distinct band due to absorption by ammonia appeared in this region

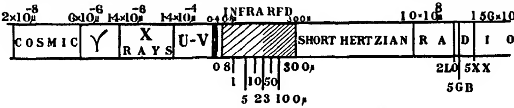

FIG 1 —Electromagnetic waves Velocity = 30 000 000 000 cm per sec = 186 000 miles per sec

OSCILLATION AND ROTATION BANDS

Bands due both to oscillation of the atoms in the molecule and rotation of the molecule itself are found in the infra red spectrum Oscillation bands were shown by Drude, from the phenomenon of dispersion in crystals, to be necessarily present, having wave lengths such as occur in this region of the spectrum, if certain smaller charged particles (electrons) are concerned in the ultra violet region As the effect is one of resonance, the atoms in a molecule respond in their vibration to radiation possessing some particular frequency, and this was illustrated by a model in which a ball suspended on a spring from the end of a light rod supported on two nodes, was made to perform vertical oscillations, whereupon a ball similarly suspended at the other end of the rod picked them up and vibrated vertically in phase with the former ball The electronic linking between the atoms prevents their oscillation being truly sinusoidal, harmonics may therefore be expected and are in fact found

Molecules also undergo rotation, and this effect is reflected in their infra red spectra The main bands are due to oscillation, but in addition the rotation of the molecule also produces bands, of a simple character in the far infra red, but in the near infra red as fringes superimposed on the oscillation bands Rayleigh, assuming on the basis

of classical mechanics a Maxwellian distribution of velocities, in 1892 showed that an oscillator emitting and absorbing at a frequency ν_0 due to its oscillations alone, would, when rotating about an axis perpendicular to its line of vibration with a frequency ν_r, emit and absorb at the new frequencies $\nu_0 + \nu_r$ and $\nu_0 - \nu_r$. This seemed at first to meet the case, as in some of the early bands, such as those of Burmeister, two broad areas occurred which the Maxwellian distribution of rotational velocities would require. In 1911, however, Nernst concluded that rotation must also be quantised, and in 1912 Bjerrum and E. v. Bahr resolved a band of hydrogen chloride into a series of small bands, which they ascribed to the effects of rotation of the molecule. This band has been better resolved by Imes and others, and from the spacing of the fringes the diameter of the molecule of hydrogen chloride has been calculated. Sommerfeld, applying the principle of Bohr, showed that the equal spacing of the fringes is best explained by quantising the moment of momentum, so that each quantum jump represents a change in the moment of momentum. If the moment of momentum $J\omega$ is taken as a whole multiple of $h/2\pi$, $J = mh/2\pi$ and $E_{\text{kin}} = \frac{h^2}{8\pi^2 J}m^2$, by the Bohr Einstein conception

$$h\nu = E - E_1 = \frac{h^2}{8\pi^2 J}[m^2 - (m+1)^2] = \frac{h^2}{8\pi^2 J}(2m - 1),$$

whence the space difference is $h/4\pi^2 J$, a result in accordance with facts. It will be seen that by putting the spacing difference $\Delta\nu = \frac{h}{4\pi^2 J}$, the moment of inertia of the molecule can be calculated, and, from the moment of inertia, given the masses of the vibrating atoms, the length of the molecule.

INFORMATION GIVEN BY INFRA RED SPECTRA

In the first place, we get the frequency of oscillation of the atoms within the molecule, and the frequency of rotation of the molecule itself. These have been shown for a simple molecule such as that of hydrogen chloride. In addition, with more complicated molecules, it is possible to construct models by taking into consideration the presence of absorption bands and assuming a law of force between the atoms in the molecule. Thus Hund considers that ammonia has a tetrahedral structure, and this is probably also the case with the analogous phosphine and arsine. With these gases at least three sequences of bands have been found in each, corresponding with three degrees of freedom of oscillation, one of the sequences in each gas having five or six harmonics. In this sequence the frequency of vibration gets slower as the weight of the atoms nitrogen ⟶ phosphorus ⟶ arsenic increases in the three gases.

It is interesting from the chemical point of view to see if any of these degrees of freedom correspond to the chemical bonds of the chemists, and some hint of this is obtained in one case at least. Thus by progressively substituting the H in NH_3 by CH_3, a certain band—the first harmonic of the main sequence mentioned above—disappears from the spectrum after the last H has been substituted, so this degree of freedom of oscillation has been identified as connected with the chemical bond N H.

Again, as regards rotation, we have found two moments of inertia in ammonia, of which one can be attributed to rotation round the median line and the other round the centre of mass at right angles to the median line. Calculation of the length of the molecule, as above described, gives a value similar to, although somewhat smaller than that obtained by Rankine from measurements of viscosity of this gas. By the comparison of spectra of related compounds, as for example in the case of hydrocarbons, definite bands have been attributed to certain groups or radicles. In the case of solids, certain groupings such as NH_4^+ or CO_3^- have similarly been identified in the spectrum of salts.

In the hands of Coblentz, infra red data and technique have been used to determine the quantity of radiation from the sun, stars, and planets, and he has also deduced the temperatures which prevail in these bodies, and even the differences in radiation from the hemispheres of Mars.

The knowledge of the infra red spectrum of water vapour and of carbon dioxide is of importance in considering the nature and quality of energy reaching us from the sun, and only recently Dr. G. C. Simpson, by making use of the absorption coefficients of water and carbon dioxide in the infra red, has deduced that an increase in solar radiation would result in increased cloud and precipitation, and even in the apparent paradox of an ice age. Further, Paschen's determination of the emission and absorption bands of these gases is fundamental in questions relating to combustion.

FUTURE WORK IN THE INFRA RED

Such are some of the results that spring from the consideration of infra red spectra. On the more theoretical side it has thrown light on and given support to the quantum theory. It has passed into the hands of the still more modern exponents of the wave mechanics and found to be in accord with their predictions, as for example in connexion with the assumption of half quantum numbers. This is a field in which its usefulness is only beginning.

Only last year, Prof. Raman of Calcutta, by imposing monochromatic radiation from a mercury lamp on gases and liquids, observed spectroscopically in the scattered light not only the original line but also others at frequency differences which he finds are equal to frequencies in the infra red at which bands characteristic of the gas or liquid were known. This brilliant experimental confirmation of the quantum theory may prove of the highest importance from a theoretical point of view when it comes to be explained why in the Raman effect not all the bands found in the infra red by the usual means appear, and why others appear to be disclosed only by the Raman effect.

Like the X rays, the infra red deals with the

structure of the molecule but while X rays reveal the molecule in its static condition and are especially applicable to solids infra red spectra reveal the dynamic characteristics of the molecule in gases liquids and to a restricted degree in solids In the future it will undoubtedly be used to a greater extent in the determination of the nature of chemical linkages and generally for a solution of problems of chemical constitution

As Garner and his school have shown important deductions can be made as to the rôle of infra red radiation in combustion as for example in the effect of water when it is present in carrying off the energy of radiation produced when carbon monoxide combines with oxygen and as the bulk of the radiation from flames is in the invisible part of the spectrum and mainly in the infra red there is here a wide field of work in clearing up the mystery of flame and the same is true as regards the phenomena of explosion of both gaseous and solid explosives

It is to be regretted however that more work is not being done in Great Britain in the exploration of this region It is true that the technique is difficult and there have been several investigations reported of an accuracy that leaves a good deal to be desired Most of the work until now has been done in Germany and in the United States little having so far come from British universities with the exception of Cambridge where there is an embryonic school The subject is perhaps scarcely one suitable for a young graduate to acquire the technique and embody a year s work in a thesis for some degree but one for a more permanent staff and I should like to make a plea for its greater consideration in Great Britain as a field of experiment and study likely to assist in the solution of many physical and chemical problems which in due course will have its reflection in the domain of technical application

Sir J J Thomson has given us the electron Rutherford the proton with its planetary electrons and the structure of the proton the Braggs have elucidated the structure of many molecular fabrics but the molecule as a dynamical entity has been comparatively neglected For it is in the infra red region of the spectrum that this behaviour can best be studied In this aspect the problem is a physical one for the most part the technique is difficult but likely to be productive of much that is important in our conception of the structure of matter It is for this reason that one would like to see in Britain a strong school arise which would have as its object the study of the dynamical behaviour of the atoms in the molecule and of the molecule itself

Obituary

PROF WILLIAM KUSTER

DR WILLIAM KÜSTER professor of organic chemistry and technology at the Technische Hochschule in Stuttgart died suddenly on Mar 5 of heart failure From the pages of a recent issue of the *Chemiker Zeitung* we glean the following details of his career

Born at Leipzig in 1863 Kuster received his early education in Berlin and studied later at the Universities of Tubingen Berlin and Leipzig At Leipzig he worked under the direction of Wislicenus with whom he remained for a while after graduation until he was appointed assistant to Hufner at Tübingen where he was given charge of the practical chemistry classes for medical students In 1894 he published his first paper on salts of hæmatin This was followed by an intensive study of the pigments of blood and bile subjects which he made peculiarly his own and remained his chief interest throughout life

In 1903 Kuster was appointed professor of chemistry and pharmacology at the veterinary college at Stuttgart and lecturer on pharmaceutical chemistry at the Technische Hochschule The duties attached to these offices were so burdensome that but little time was available for research Moreover at the veterinary college he found that no provision had been made by his predecessor for experimental work In spite of these difficulties he succeeded during the next eleven years in publishing numerous papers on hæmatin porphyrin pyrrole, and bile pigments

On the retirement of Prof C von Hell, the department of chemistry at the Technische Hochschule at Stuttgart was completely reorganised and Kuster was appointed to the chair of organic chemistry and technology Under his direction the department was greatly enlarged and in spite of the difficult nature of the work in which he was engaged he attracted a great number of research students to assist him in his investigations In this way Küster and his collaborators were able to make a large number of important contributions in the field of biochemistry Later his interest extended to other branches of natural products such as sugar albumen lignin etc He also contributed to the well known handbooks of Abderhalden and Thoms

WE regret to announce the following deaths

Prof Jules Cornet the distinguished geologist and professor in the University of Ghent and at the School of Mines at Mons *correspondant* of the Paris Academy of Sciences who was well known for his geological explorations in the Congo in 1892 and 1895, on May 17

Mr Stewart Culin curator of ethnology in the Museum of the Brooklyn Institute, Brooklyn, N Y, known especially for his comparative studies of the games of North American Indians and other races, on April 8 aged seventy years

Prof Charles Depéret professor of geology in the University of Lyons and a foreign correspondent of the Geological Society of London on May 17, aged seventy four years

M Ulysse Gayon a distinguished biologist and chemist and honorary doyen of the Faculty of Sciences at Bordeaux, aged eighty three years

News and Views.

In the short address which he delivered at the dedication of Darwin's home to the nation on June 7 (Nature, June 8, p 875), Sir Arthur Keith touched upon the relationship between sentiment and science When sentiment enters a laboratory by the back door science takes the earliest opportunity to escape by the front, yet, since life is as it is, science cannot easily be cut adrift from personality The value of such a gift as that which Mr Buckston Browne has made to the British Association lies in the power of the personal associations of its material contents and surroundings to throw the visitor back into the very atmosphere of the century and of the place in which Darwin moved and thought So a background of sentiment is formed which illumines and may help to interpret the development of the man's mind and the direction of his labours Down House is a memorial, not to Darwin's science, which will outlast our buildings, but to his personality It is especially appropriate therefore, that the donor should have expressed the wishes that the house and grounds should be maintained in a state as near as possible to that in which Darwin modelled them, and that they should be used to advance the cause of science, in ways in which the Council of the British Association thinks best "If any place can provide inspiration for research it should be Darwin's own gardens"

Sir Arthur Keith's presidential address at the annual congress of the South Eastern Union of Scientific Societies on June 5 at Brighton was singularly happy both in subject and method of treatment In demonstrating the racial characters of the pre Roman inhabitants of Southern England, he was able to draw much of his material from discoveries on the South Downs relating to prehistoric man, and to refer to material evidence deposited in local museums Taking the skeletal remains found in the neighbourhood of Brighton, the Maycroft skeleton, the Ditchling and Blackpatch (Worthing) finds, he linked them up with the crouched burial discovered at St Catherine's, in the Isle of Wight, some three years ago Hence by means of the identification by Mr O G S Crawford of a peculiar piece of pottery found in 1881 in a burial at Nunning, some ten miles from St Catherine's and preserved in the Carisbrooke Castle Museum, he was able to relate the Brighton folk as kin to the Beaker folk who settled in Britain at the end of the neolithic and beginning of the Bronze Age some two thousand years before Christ, a relation to which the skeletal remains had pointed, but for which cultural evidence indicative of a chronology had been lacking It was outside Sir Arthur Keith's purpose to trace the Beaker folk back to their origin on the continent, but he did refer to the related flint miners of Belgium, this enabling him to offer an interesting suggestion of child sacrifice as a possible explanation of the discovery of skeletons of children buried with those of adults

It is unnecessary now to follow Sir Arthur further, when, pointing out the gap in our knowledge of the physical characters of the inhabitants of Britain after the settlement of the Beaker folk, he turned to trace the history of the people of Southern England back through the finds which could be dated to periods immediately preceding the Roman invasion It may be noted, however, that here again he gave full weight to local investigation and also to those of Mr and Mrs Cunnington at All Cannings Cross and Woodhenge In fact, throughout the whole address it was patent that he addressed a wider public than his immediate audience, and had in mind the broader aspects of the specific problems with which he was concerned His brilliantly lucid reconstruction of the racial history of prehistoric Southern England was in fact a convincing demonstration of the methods of study of prehistory and an eloquent plea for a wider recognition of the value of archæology in the reconstruction of history Sir Arthur Keith brought out even if he did not specifically stress in every instance, the value to archæological studies of what may be termed localised research It has been mentioned that his material was largely drawn from local investigations Not only was this the case, but also it was by means of the correlation of local records and the examination of local evidence when housed in museums within reach of its original environment that this pregnant comparative study was made possible Hence Sir Arthur Keith's address should provide a stimulus to all local archæologists and all local scientific societies

After the great paroxysmal eruption of Vesuvius in 1906 there followed seven years of obstruction and comparative repose In 1913 the conduit became open and the normal type of external activity began Since then the crater has been steadily filling from a succession of central conelets, and at intervals in recent years there have been minor crescendos of explosive and effusive activity By far the greatest and most spectacular of these broke out in the early hours of June 3 The outburst began with tremendous explosions and the hurling into the air of masses of incandescent material The central conelet split and collapsed As it fell back into the crater lava welled out and occupied the north eastern quadrant of the crater Prof Malladra announced on June 3 that he considered the eruption to be one of the periodic recrudescences of activity, that it was unlikely to last more than two or three days, and that a disastrous eruption of the culminating type—such as those of 1872 and 1906—was not yet to be expected

On the morning of June 4 it became clear that for a minor eruption the manifestations were more than usually violent The interior of the crater now became a lake of effervescing lava some 500 yards in diameter The lava overflowed into the Valle dell Inferno and escaped down the outer slopes into the valley of Cuppaccio and towards the little town of Terzigno, following the course of the 1834 lava-stream After a short interval of quiescence from 2 30 to 7 30 P M there was a sudden paroxysm of activity for three quarters of an hour Incandescent matter rose

1500 feet above the crater and fell in glowing showers on the slopes of the volcano Afterwards there were loud and frequent explosions, followed by an ash cloud that rose to still greater heights From 11 P M on June 5 to 3 A M on June 6 there were further tremors and explosions, and columns of lava were thrown into the air to break into incandescent bombs Since then there have been (at the moment of writing) no further reports of activity The lava stream has extended five miles down the south eastern slopes, widening to a frontage of 900 yards, destroying 110 acres of cultivated land and wiping out three small hamlets Although Terzigno was evacuated with the prompt aid of the military, the township itself has fortunately been spared, the lava having halted 300 400 yards from the houses It is estimated by Prof Malladra that the volume of lava approaches half that emitted during the 1906 eruption

THERE is a remarkable article in the June number of the *Realist* which will arouse interest and, it may be hoped discussion in wider circles than even the readers of this journal It is a merciless, and on the whole well founded analysis—most people would call it an exposure—of Wordsworth's appreciation of Nature Prof Herbert Dingle in "The Analytical Approach to Wordsworth", shows by abundant quotations what was the actual mental attitude of the poet towards the Nature which he worshipped It was not one of questioning or of interest in the changes or process of Nature but of passive meditation and happy acquiescence in scenes and thoughts which were familiar to him He does not seek for truth but for a mystic sublimity of feeling of which the attainment was a solemn duty of man He never therefore particularises either in describing a person or a natural object Cliffs are simply 'lofty' and trees 'dark', just as his human beings are distinguished not by their interesting peculiarities but by their age or their occupation, things common to a host of people

PROF DINGLE scarcely does justice to the stimulus towards science given by the preface to the second edition of the "Lyrical Ballads" in 1800, which is one of the most admirable things in English criticism and puts the man of science and the poet in a friendly and natural relation together Yet even in speaking of this, Prof Dingle manages to put his finger on a weakness, or at least a limitation, of Wordsworth's attitude The poet when speaking of the labours of the man of science regards him as isolated from the poet it is only when finished products are reached that the poet can take them up and make use of them Just as in science Wordsworth would make use of the finished product, so in human society he tends more and more to dwell on the past His attitude is thus almost completely static, as Shelley's by his burning forward vision and exuberant imagination becomes vague and unreal The whole question is of extraordinary interest and it is much to be hoped that critics interested both in science and poetry will take it up Sully Prudhomme raised the same point in France about a hundred years later and lamented how little influence the strides of science had exercised on the inspiration of poets in the interval Perhaps the growth in mass and specialism of science makes contact all the more difficult what Prof Dingle makes us desire is a greater community of spirit

IN *Engineering* for May 31 is an illustrated account of the famous Carl Zeiss Optical Works at Jena, which owe their foundation to the partnership of Carl Zeiss (1816–1888), an instrument maker, and Ernst Abbe (1840–1905) the physicist, begun in 1866 At one time the works employed nearly 10,000 men and women, and in the article is a plan showing the development of the Zeiss Factory at various periods and the recent extensions The original workshops were in the town of Jena, and in 1876, by which time the 3000th microscope had been sold, the present site was purchased In the early 'eighties Otto Schott, the glass maker, became associated with Zeiss and Abbe, but the glass works, though administered by the Carl Zeiss Foundation, remains independent of the instrument factory Brief accounts are given of Abbe's contributions to mathematical optics, of the manufacture of optical glass, and of the formation and working of the Carl Zeiss Foundation, and together with these are a few details regarding the planetaria constructed by the firm, and of the Zeiss double refracting telescope sent to the Lembang Observatory, Java, and of the 650 mm refractor finished in 1914 for the Neu Babelsburg Observatory, Potsdam

IN the same issue of *Engineering*, in a Supplement dealing with the exhibits at the North East Coast Exhibition, Newcastle upon Tyne, opened by H R H the Prince of Wales on May 14, is a short description of the 36 inch reflecting telescope made by Messrs Sir Howard Grubb, Parsons & Co, for Edinburgh Observatory Built to the specifications of Prof Sampson, Astronomer Royal for Scotland, the telescope is mounted equatorially, three rates of motion being provided for both axes, the fastest giving one revolution in 3 minutes, while for fine setting the rate of movement is one revolution in two days and for guiding one revolution in 60 days The optical system is that introduced by Cassegrain in 1672, the main mirror of parabolic form being 37 in in diameter, 6 in thick, and having a central aperture $3\frac{1}{2}$ in in diameter Its focal length is 15 ft The Cassegrain mirror, near the upper end of the tube, is of hyperbolic section, 10 in in diameter, and is designed to give an equivalent focal length of 54 ft in conjunction with the main mirror The instrument will be installed in Edinburgh Observatory at the close of the Exhibition

THE eighty second annual meeting of the Palæontographical Society was held in the rooms of the Geological Society, Burlington House, on May 31, Dr F A Bather, president, in the chair The annual report announced the publication at an early date of new monographs on Corallian Lamellibranchia, by Mr W J Arkell, and on Cretaceous Terebratulidæ, by Dr M R Sahni It also made special reference to the death of one of its oldest members and most

valued contributors, Sir William Boyd Dawkins Mr A J Bull, Dr O M B Bulman, Dr L F Spath, and Mr S Hazzledine Warren were elected new members of Council Dr F A Bather, Mr Robert S Herries, and Sir A Smith Woodward, were re elected president, treasurer, and secretary respectively In a brief address, the president alluded to the numerous gaps in the series of monographs on British fossils which still existed, and made suggestions for future work

THE Medical Research Council, after consultation with the Ministry of Health and the Board of Education, has appointed the following committee to inquire into the prevalence and mode of spread of minor epidemics in residential schools especially those believed to be spread by 'droplet infection', and to report upon the means by which they may be prevented or restricted Sir George Newman (Chairman), Dame Janet Campbell, Dr R H Crowley, Surgeon Comdr S F Dudley Dr J A Glover Prof M Greenwood, Mr L R Lempriere Miss E M Newbold, Prof W W C Topley, and Mrs Joyce Wilson (Secretary)

DURING the past season the price of oysters has remained at a high level, owing mainly to the scarcity of stocks In an article on British Oyster Fisheries published in NATURE of March 23, Dr J H Orton discussed the various causes for this scarcity and indicated, in particular, the dangers of over fishing In this connexion it is worth while to direct attention to a "Report on a Survey of the Fal Estuary Oyster Beds" (November 1924) "With Notes on the Biology of the Oyster" (published by private subscription at Falmouth, 1926, but obtainable from the Marine Biological Association, Plymouth, price 2s 6d), in which Dr Orton deals with a particular depleted fishery and suggests various measures to restore it to a productive state The report is of great value to all concerned in the investigation and administration of oyster fisheries, but being privately printed it may easily escape the notice of those interested

THE bird sanctuary at Duddingston Loch, in the Royal Park of Holyrood in Edinburgh, is making satisfactory progress, and the third Report of the Committee (Edinburgh and London H M Stationery Office 6*d* net) shows that its members are keeping close watch on the development of the area Further planting of trees has taken place, with the object of forming a screen to keep out engine sparks from the neighbouring railway, to which was due a disastrous fire in the spring of the previous year One of the problems of the Loch has been the remarkably few aquatic species of birds which reared young to maturity in spite of the large number of nests, and this is attributed partly to the presence of many pike in the Loch itself, and partly to the frequent attentions of some lesser black backed gulls An attempt was made to reduce the former by dragging the loch, the latter emphasise the danger run by any policy of wholesale and indiscriminate protection The entomological and botanical surveys of the area inaugurated in 1927 with the view of studying the interrelations between plant and animal life have been continued, and a short note on the entomology of the sanctuary, by P H Grimshaw, of the Royal Scottish Museum, concludes the report

THE story of the Greenland whaling industry, in which Great Britain shared in the seventeenth and eighteenth centuries, has been traced in connexion with many of the seaports taking a major part in the 'fishery' For the first time, however, an attempt has been made to give a consecutive account of the whaling of the port of Aberdeen, in an excellent article by James Pyper, in a recent issue of the *Scottish Naturalist* (p 39) In 1749, for the first time, whaling vessels sailed from Scotland, and in 1752 Aberdeen entered the trade with two vessels By 1814–17 the port stood only after Hull and London in the number of its whaling ships and its tonnage of oil Five years later London had dropped out of the first rank, and Peterhead, with 16 vessels, stood second to Hull with 40, Aberdeen, with 14 following third In the average tonnage of oil per vessel, however, Aberdeen now stood first, the total cargoes amounting to 1225 tons It was a small return compared with the enormous catches of the present day finner industry, but it spelt a season of prosperity for the northern seaport The account gives a vivid notion of the ups and downs of the fishery Of the ten ships which sailed in 1830, four were lost in the ice with six of their crews, two ships returned from the fishing 'clean', one had two whales, and the remaining three, a single whale each

THE Report for the year 1928 of the National Physical Laboratory covers 284 pages, of which 200 are devoted to detailed accounts of the work carried out in the various departments These accounts are well illustrated and show that the Laboratory continues to maintain its position as one of the most active centres of research into questions bearing on our national industries The projected new physics building, which has been referred to in the annual reports for many years, is now under construction so far as its central block is concerned, and the scattered rooms in the basement and other parts of Bushy House previously occupied by the Physics Department are to provide accommodation for the Electrical Standards and other departments Work on standards of measurement has been carried on actively during the year, and with the increase of test work for the industries has diminished the time devoted to general research The high voltage equipment is nearing completion and will enable tests up to a million volts to be made A useful addition to the report is a section of 20 pages giving precise definitions of the units and standards of measurement employed at the Laboratory

IN his discourse on "Excavations at Ur, 1928–1929", at the Royal Institution on June 7, Mr C Leonard Woolley gave a short account of the final clearing of the great temple of the Moon god Nannar, whose history was traced from the foundation of the building by king Ur Nammu about 2300 B C until its last restoration by Nebuchadnezzar in the sixth century B C The main part of the lecture was devoted to a

record of the continued excavation of the prehistoric cemetery More royal tombs were found, two of which gave entirely new information as to the ritual of a king's funeral, one of these was intact, and the tomb chamber, the stone dome over which was found unbroken, contained some remarkable gold objects Much richer than this was a 'death pit' containing seventy four bodies, many of them lavishly decorated with gold, and four harps and two statues, these are among the finest objects of art yet discovered in the cemetery Other graves produced a very large collection of funeral furniture in gold, silver, copper, stone, and clay, of which the more important were illustrated Finally, a description was given of the work carried on at a lower level than the graves, which resulted in finding evidence of the historical character of the Flood

IN Basel on Oct 8–12, 1928, was held an interesting short course upon the use of electrostatic methods in biochemistry and biology, in which a group of scientific workers gathered from various centres were introduced particularly to the work of the Prague school (Prof R Keller R Furth, etc) Some of the communications given at this 'school' are published in the *Kolloidchemische Beihefte*, vol 28, 1929 (pp 208 390) After general introductory papers by Prof Spiro, of Basel, and Prof Keller, papers were given upon methods of measuring electric potentials in the organism, upon the preparation of micro electrodes, pH determination in living organisms, upon the use of vital staining in biology, upon dispersoid analysis by a new dialysing apparatus, etc In all many new experimental avenues of approach to biological problems were discussed and some results obtained by these new methods briefly indicated Many new fields of biological investigation are being actively pursued by this group of investigators, who are introducing physical methods into biochemistry and biology, and this collection of papers illustrating their outlook will be of interest to workers in widely different fields

THE great demand for cheap electrical power for heating makes it necessary to raise the transmission voltage to the highest permissible limit, as otherwise the cost of the large amount of copper in the mains is prohibitive from the commercial point of view Even to relatively short distances, a voltage of 132,000 is being used In Berlin quite recently an overhead line several miles in length for transmission at 100,000 volts has been erected in the suburbs of the city The question of carrying this line to the centre of the city is at present under consideration, and in all probability underground mains will be used In Hamburg there are at present two cables, each nine miles long, working at 60,000 volts, and in Nurnberg there is an underground cable connecting two net works, which works at 110,000 volts In the event of a fault to earth occurring on a high tension cable, a very large current will flow, and the cable will be seriously damaged for several yards on each side of the fault An interruption of the supply will probably ensue A method of preventing this is described in *A E G Progress* for April The high voltage underground networks are connected with Petersen arc suppressors In the event of a fault occurring these devices allow a lagging current to flow through the fault This combines with the 'capacity to earth' current at the point, making the voltage of the cable at the point practically zero and preventing a serious fault from developing It prevents also the development of high frequency currents which arise when an arc ensues These currents, as Duddell pointed out many years ago, may cause resonance voltages at points remote from the fault and so break down the insulation of the cable In Great Britain and in America, steady progress is being made in the development of very high voltage cables, but we think more attention should be paid to developing devices to safeguard them when in operation

THE Medical Research Council announces that, on behalf of the Rockefeller Foundation, it has made the following awards of travelling fellowships for the academic year 1929–30 These fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine and surgery, and who are likely to profit by a period of work at a chosen centre in America or, in special cases, in Europe, before taking up positions for higher teaching or research in the British Isles Olive B Buckley, Dr G A C Gough, W R Henderson, Dr D Hunter, G E Lewis, Dr M M Suzman, Janet M Vaughan Dr Gough's fellowship is tenable at the University of Munich, the others at centres in the United States

THE condition of St Mary's Abbey has caused concern to the Council of the Yorkshire Philosophical Society, and following upon a thorough inspection and report by H M Office of Works, it has been recommended that certain steps should be taken to improve the amenity of the site and to ensure the preservation of such portions as remain The estimated cost of the work proposed is £3370

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in economic history and economics at Armstrong College, Newcastle upon Tyne—The Registrar, Armstrong College, Newcastle upon Tyne (June 19) Two forest officers under the Forestry Commission—The Secretary, Forestry Commission, 22 Grosvenor Gardens, S W 1 (June 20) Two temporary investigators and a temporary assistant under the Department of Agriculture for Scotland, in connexion with an inquiry into the marketing of livestock and other agricultural produce in Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (June 21) A teacher of agricultural science under the Londonderry and Limavady Regional Education Committee—The Principal and Secretary, Education Office, Limavady, Co Londonderry (June 22) A Paterson research scholar in the Cardiographic Department of London Hospital—The House Governor, London Hospital, E 1 (June 22) An advisory officer in agricultural botany at the Edinburgh and East of Scotland College of Agriculture

—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (June 28) A lecturer in geography at Armstrong College, Newcastle upon Tyne—The Registrar, Armstrong College, Newcastle upon Tyne (June 28) An assistant part time lecturer in the biology department of the Plymouth and Devonport Technical College—The Education Office, Rowe Street, Plymouth (June 29) A full time teacher, for building trade subjects, at the Cheltenham Technical School—The Principal, Technical School, Lansdown Road, Cheltenham (June 30) Four assistant conservators in the Indian Forest Service—The Secretary, Services and General Department, India Office, S W 1 (July 1) An assistant in geography at the London School of Economics and Political Science—The Secretary, London School of Economics, Houghton Street, W C 2 (July 1) A mining engineer under the Safety in Mines Research Board—The Under Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, Millbank, S W 1 (July 2) An assistant or junior lecturer in the department of zoology of the University of Edinburgh, with special knowledge of invertebrates—The Secretary the University Edinburgh (July 5) A professor of physiology at the Medical College, Vizagapatam, Madras — The Secretary to the High Commissioner for India, General Department, 42 Grosvenor Gardens, S W 1 (July 6) A senior lecturer in biochemistry in the University of Stellenbosch, South Africa—The Registrar, University of Stellenbosch, Stellenbosch, South Africa (July 31) A lecturer in mathematics at the Gordon College, Khartoum—The Controller, Sudan Government, London Office, Wellington House, Buckingham Gate, S W 1 A resident tutor (woman) to take geography and some education at the Edgehill Training College, Liverpool—The Principal, Edgehill Training College, Liverpool A lecturer in electrical equipment of the motor car at the Wimbledon Technical Institute—The Principal, Technical Institute, Gladstone Road, S W 19 A teacher of building subjects at the Croydon Polytechnic—The Principal, Croydon Polytechnic, Scarbrook Road, Croydon A lecturer in building at the Huddersfield Technical College—The Director of Education, Education Offices, Huddersfield A male junior assistant at the Chemical Warfare Research Department of the War Office—The Chief Superintendent, Chemical Warfare Research Department, 14 Grosvenor Gardens, S W 1 An assistant lecturer in physics at the University College of Hull—The Secretary, University College, Hull An assistant in the mechanical engineering Laboratory of University College, London—The Secretary, University College, Gower Street, W C 1 Two male laboratory assistants in the Research Department, Woolwich, with laboratory experience in physics—The Chief Superintendent, Research Department, Woolwich S E 18 A head of the experimental branch under the directorate of ballistics of the Research Department, Woolwich—The Chief Superintendent Research Department, Woolwich, S E 18

Our Astronomical Column

FIREBALL OF MAY 30 —A brilliant fireball was observed from several stations in Cornwall on May 30 at about 11 0 P M G M T Observations have however, come in from only Lostwithiol and Bugle, and these are of somewhat rough character The meteor gave a very brilliant flash and lit up the surroundings to such a degree that the observers found it difficult to note exact features of the path It passed along the southern sky from west to north and was evidently from a radiant in the eastern region of the heavens Its motion was moderately slow, for it occupied 4 or 5 seconds in its flight One of the observers, who was walking in the direction away from the object, says that he observed a great light behind him as though a brilliantly illuminated motor car was overtaking him It appeared like a dazzling ball of fire, but when a good view was obtained of it the nucleus appeared relatively small, though surrounded by a strong glare which apparently lit up the country Further observations are required of this interesting object, which came on the night of the general election, and on this account may have attracted notice from a greater number of observers than it would otherwise have done

VENUS A MORNING STAR —Venus is now a 'morning star' and will continue to precede the sun during the remainder of the present year The planet will attain its greatest elongation on June 29, when its position will be 46° west of the sun Its brilliancy is now declining, but not to any great extent Atmospheric conditions introduce more variations than are sometimes brought about by real differences Thus Venus will appear brighter when its computed lustre is less and when the air is very clear, than at a time when atmospheric vapours dim its light

Venus is now approaching Jupiter and the two planets will arrive at conjunction on July 14 at 10 A M, when Venus will be placed about 3° S of Jupiter Before sunrise this pair of attractive objects may be viewed in the E N E sky before sunrise Venus rising ten minutes after midnight, and Jupiter fifty seven minutes after midnight If the morning sky is clear the two planets may be easily identified and their relative brightness compared

SATURN —The planet Saturn will reach opposition to the sun on the night following June 21 The apparent magnitude will be + 0 2, and the planet will appear brighter than at an ordinary opposition because of the more favourable conditions prevailing The rings will be widely open and the planet will be situated almost midway between aphelion and perihelion At an unfavourable opposition, Saturn may shine as a star of + 0 8 mag only, but with attendant conditions favourable it may appear as a + 0 2 mag star It is true the aspect is by no means starlike, for the planet shines with a steady, dullish light, much in contrast with the sparkling diamond like brilliancy of the fixed stars At the time of Saturn s best display this year, its position will be placed on the extreme west border of Sagittarius, and as the planet is moving westwards it will shortly after enter the south region of the constellation Ophiuchus, and be visible to the north east of the star 44 Ophiuchi For critical observation the planet cannot be considered in a good position, its declination being 22° south, and its altitude, when passing the meridian, not greater than 16° or 17° to observers in the south of England

Research Items

INHERITANCE FEES.—In *Man* for May, Mr. J. P. Driberg directs attention to an element in primitive marriage which appears to have escaped general observation, namely, the inheritance fees or dues paid by an inheritor of a widow to the responsible members of her family. Such a fee has been found to be compulsory among three unrelated peoples—the Lango of Uganda, and the Didinga and Bari of the Sudan. Among the Lango a widow is normally inherited by a brother of the deceased or by his sister's son: in either case a bull being payable to the woman's family. She is differentiated from the wives by being called an inherited wife. Among the Didinga the deceased's brother pays the fee and calls the children his own; but if a sister's son or mother's sister's son inherits the widow, the son pays the fee and claims any children of the new marriage. Among the Bari, when a sister's son inherits, the fee is paid from the estate and the children belong to the estate. This seems an anomalous custom, as the bride's family had already received the full price from the original husband. It arises from an intention of making clear the economic and social status of the children of the new marriage. Marriage is not regarded as completed until the birth of the first child. The bride may not be called a wife till then. Sometimes she only lives in the bachelor's hut until the child is born. In the case of a divorce the bride price is returned and the children go with the mother; but the father even after years may recover the children on payment of the 'heifer of upkeep' to the family of the girl or her new husband. Among the Bari, if a marriage takes place without payment of the bride price, the wife's family take all the bride price paid at the marriage of the first daughter of the union. If there is no daughter the family keeps a son until he is ransomed.

THE SHISHAK MIGRATIONS.—Sir Flinders Petrie in *Ancient Egypt*, Pt. 4, 1928, states that the excavations at Gerar (Palestine) have produced repeated evidence of a movement from Central Asia to the west at about 950 B.C. Pottery models of square waggons with divisions from front to back and with two types of pottery wheels, one smooth, the other knobbed, are found. Similar waggons come from Anau, and knobbed wheels occur in the treasure of the Oxus, from 300 miles farther east. The latter wheel is designed to prevent sinking in sand and belongs to desert dwellers. Two types of bronze arrowhead come from Central Asia, one with a tang similar to a type found at Tomsk; the other is the triangular bladed arrowhead of Minussinsk, Altai, Perm, Siberia, and south-west Caspian. The broad bladed iron dagger belongs to Anau, the Caspian, and Caucasus. Lastly, all the pottery figures of oxen are humped, a central Caspian type not found west of Mesopotamia. This movement, dated at 970 B.C., links with Sheshenq, the 'Man of Susa' entering Egypt. Shushinak is the national deity of Elam, worshipped at Susa, and was also a great deity among the Persians. The attribution of Libyan descent to Sheshenq is due to a misreading of the genealogy of Horpasen. His name labels his origin plainly. Further, owing to the practice of hepatoscopy, a Babylonian connexion has been suggested for the Etruscans. Now the horned head-dress of divination, the vases of offerings in Etruscan tombs in the shape of a cone with two globes over it, and other evidence point to a middle Asian origin for the Etruscans, and, it is suggested, link them up with the westward movement of Turkomans, of which evidence is found at Gerar, and of which the coming of Sheshanq to Egypt formed part.

THE EXTERMINATION OF THE HEATH HEN.—The heath hen of America (*Tympanuchus cupido*), a near relative of the prairie hen which abounds on the prairies of the Mississippi valley, provides one of those problems of casual extermination which man seems powerless to stay. Fifty years ago the heath hen was a common bird on the island of Martha's Vineyard, to which it was confined. But about fifteen years since its numbers were reduced with remarkable suddenness. Attention was directed to the danger and thousands of dollars were spent in an effort to protect the birds. We now learn from a *Daily Science News Bulletin*, issued by Science Service, Washington, D.C., that even so late as 1916 there still survived about 1000 heath hens on the island reservation, and fears of their extinction were allayed. Then, just at the time when the hens were sitting on their eggs, a disastrous forest fire swept over the area, causing the loss of the year's brood as well as of many of the females. It is said that the inbreeding of the few surviving birds weakened the stock, which became subject to some of the common poultry diseases. Two years ago ornithologists were able to find only 30 specimens on the island; in a year the number was reduced to nine, a little later to three, and then to two. Now only a single specimen is known to exist—the heath hen of Martha's Vineyard is virtually extinct.

AN ALLEGED ANTHROPOID APE EXISTING IN AMERICA.—A discovery of extraordinary interest is that recorded by Dr. George Montandon in *La Nature* of May 11, where he describes from a photograph, which is reproduced, a supposed anthropoid ape from South America. A pair of the apes was seen by M. François de Loys in the virgin forests on the borders of Colombia and Venezuela, and the female was killed. It measured about 1.6 m. in height, and, as the photograph shows, had a distinctly human appearance. Moreover, the beast had no tail, and its teeth are said to have numbered 32, although, most unfortunately, the skull was afterwards damaged during the expedition and was eventually lost. On the strength of these characters, and particularly of its size and appearance, Montandon regards the creature as a new anthropoid ape related to the gibbons but bearing a resemblance in its coat and in the proportions of its limbs to the orang-utan. Accordingly he names it *Ameranthropoides loysi*, after its discoverer, and makes use of its presence in America to support his theory of the parallel development of anthropoids in America, Asia, and Africa. On the whole, in view of the scanty evidence, we prefer the caution of Prof. L. Joleaud, who in a subsequent paper in the same number of *La Nature* suggests that the new monkey is probably not a true anthropoid ape, but a specialised relative of the spider monkeys (*Ateles*).

ANATOMY OF A FŒTAL AFRICAN ELEPHANT.—Dr. N. B. Eales (*Trans. Roy. Soc. Edin.*, vol. 56, Pt. I, 1929) completes her study of the African elephant based on the examination of a well-grown fœtus. Previous parts dealt with the anatomy of the head and with the body muscles. The final part deals with the remainder of the organs. The most interesting feature in the anatomy of the elephant is the reduction of the pleural cavities shortly after birth by the ingrowth of trabecular connective tissue from the thickened costal and dorsal pleura. The result of the obliteration of the pleural cavities is to reduce costal movements during breathing to a

minimum and to make respiration in the elephant largely diaphragmal The elastic tissue helps to control the powerful diaphragmatic movements so that the air is not sucked too violently through the long nasal tubes The diminution of the collapsing power of the lungs consequent on their adherence to the walls of the chest has rendered intra pulmonary cartilages unnecessary In the light of her investigations, Dr Eales discusses the relationships of the two living species of the Proboscidea, and the affinities of the group as a whole She agrees with the view of the palæontologists that the African and Indian elephants should be placed in two distinct genera *Elephas* (Indian) and *Loxodonta* (African) The characters of the two genera are summarised and the view adopted that they belong to different lines of descent Discussing the affinities of the Proboscidea as a whole, Dr Eales shows that their characters bear evidence of affinities with the stock from which sprang the rodents Sirenia Hyracoidea and the primates, and that their nearest relatives are the Sirenia and the Hyracoidea The Ungulates are not near them in descent She therefore supports the modern view that the Proboscidea should be elevated to the rank of order and removed altogether from the Ungulata

RECLAMATION OF MOSS LAND —Although much work on reclamation of moss land has been done the essential principles of the treatment have never been properly established Some experiments, described by J Gillies (*Scottish Journal of Agriculture* 12, p 126), have recently been carried out on a large tract of this type of land in Dumfriesshire and some fundamental results obtained Before any reclamation by manurial or other treatment can be attempted effective drainage is essential Dung was the best type of manure for the purpose but it would be difficult to obtain in sufficiently large quantity for work on a large scale Gradual improvement might however, be secured by grazing stock introduced at intervals from fertile land For correcting acidity various forms of lime are suitable but they all proved of little value unless phosphate was also supplied the commercial grades of basic slag, mineral phosphate, and superphosphate are the types of phosphatic fertiliser most likely to prove of economic value Potash and quick acting nitrogen on the other hand, produced no visible improvement Direct seeding with grass and clovers in July yielded very good results if manures were supplied, particularly where dung could be given Germination, however, failed completely on untreated moss or where lime only was added Care was necessary to avoid overshadowing of the introduced species by the natural moss in the early stages of growth, tramping by stock or any other method which tended to consolidate the surface being very beneficial Red and white clovers, cocksfoot, Italian and perennial rye grass, tall and meadow fescues all germinated freely and were easily established Rose bay willow herb is a serious trouble in any reclamation work, and if strong measures are not taken to suppress it, the moss land may merely change to an equally valueless tract of willow herb

HYBRIDISATION OF THE MOLLUSK *CERION* —Dr Paul Bartsch, Curator of Mollusks in the U S National Museum, has for some years experimented in hybridisation with various species of *Cerion* In August 1928, whilst visiting the Tortugas Laboratory, he examined his enclosures in which had been placed young individuals of *Cerion viaregis* and *Cerion incanum* and succeeded in finding one adult which he claims to be a perfect hybrid (Year Book No 27 of the Carnegie Institution of Washington, 1928) Criticism was expressed after the original crossing experiments, because Dr Bartsch had employed large groups (500 individuals), and it was suggested that the organisms claimed to be crosses were possibly mutations of one of the two species involved To settle this point restricted areas (cages or islands) were used one virgin individual of each of the two species being placed in each isolated area There was a large mortality, but in one cage the adult hybrid was found This is identical with those assumed to be hybrids in the mass experiments a result which was to be expected as in no colony of *C viaregis* nor *C incanum* has any individual appeared comparable in appearance to the hybrids in question It is to be hoped that more of these interesting forms will be forthcoming

THE BREAD FRUIT OF TAHITI —It is unusual in a modern botanical monograph to find a description of thirty two varieties of a plant species which contains no scientific names The bread fruit is usually regarded as a cultivated form of *Artocarpus incisa* but according to Raoul the name bread fruit should not be attached to the wild tree of Malaysia with fertile seeds described by Linnæus with this Latin name, but should be restricted to the cultivated tree of Oceania, for which no other Latin name is at present available Gerrit Parmile Wilder describes thirty two varieties of this tree found growing in Tahiti and Moorea, the fruit and foliage of each variety being illustrated by photographs in *Bulletin* 50 of the Bernice P Bishop Museum One of these varieties Huora produces true seeds but all are propagated vegetatively usually by root cuttings This monograph describes fully the native method of preparing the fruit for the table, and the value assigned by the natives to the edibility of the different varieties The author makes the interesting comment that he noted no insect fungus, or other pest upon the bread fruit tree which has been in cultivation on these islands long before it was first seen by Europeans in the Marquesas in 1595

VIRUS DISEASE OF PLANTS —Recent work in Queensland Australia, with which Prof E J Goddard has been associated, seems to have demonstrated beyond doubt that the economically important disease of the banana known as bunchy top is a virus disease with an aphis vector An account of further work upon this disease, with suggestions as to its control, is given in Vol 2 No 1, of the *Journal* of the Council for Scientific and Industrial Research of the Commonwealth of Australia Prof Goddard has drawn upon his experience in this investigation in his presidential address to the Royal Society of Queensland, published in Vol 40 No 1, of the *Proceedings* of the Society He evidently inclines to the view that the virus will be found in the category of living organisms, ultra microscopic in size, and therefore presumably forming an intermediate step between the molecular organisms of the inanimate world and the cellular organisms of the visible animals and plants He does not deal, however, with one puzzle which this point of view presents to the investigator If such ultra microscopic forms of life exist, why are they not to be found leading a saprophytic or even an autotrophic existence? Until now, attempts such as have been made by Hugo Miehe (*Biolog Centr*, 43 1924) to cultivate such ultra microscopic saprophytic organisms have failed to produce any evidence of their existence

DIFFERENTIATION IN THE SILL OF PIGEON POINT — A valuable study by F F Grout of the association of anorthosite and granite with dolerite in the great 'diabase' sill of Pigeon Point, Minnesota, appears in the *Bull Geol Soc America*, vol 39, 1928, p 555 A

chilled doleritic roof phase intervenes in most places between the acid differentiates and the quartzite roof Locally this phase contains abundant phenocrysts of labradorite, and these pass here and there into masses of anorthosite These light masses apparently rose in the magma at an early stage because of their lower specific gravity Some assimilation of quartzite by the magma is indicated but it is suggested that the granite was probably formed essentially by differentiation, with assimilation as a merely subsidiary factor The occurrence of granite at Pigeon Point is ascribed to the unusual thickness of the sill (250 700 ft) which allowed ample time during cooling for differentiation to occur The composition of the average dolerite magma is such that granite could be formed from it by crystallisation or by the separation of partially miscible fractions in about the proportions actually found at Pigeon Point Numerical data indicate that probably much less than a quarter of the total granite was due directly or indirectly to assimilation of sediments

TRANSMISSION OF SOUND WAVES IN THE EARTH —The solution of the problem of underground communication through earth strata would be of great value to miners Unfortunately its solution offers great difficulties The ideal method should enable miners to communicate no matter the nature of the strata, whether they are water bearing or not and also whether they are broken up by old workings The apparatus must be cheap light, and able to withstand rough usage A large number of experiments have been undertaken by the United States Bureau of Mines to find out the best way of communicating between miners entombed by a disaster and persons on the surface As many of the bituminous coal mines in America are comparatively shallow, even a partial solution would be of value to them In *Technical Paper*, No 433, of the Bureau of Mines, experiments on communication by L C Ilsley, H B Freeman, and D H Nellers are described Owing to the great developments taking place in radio it was hoped that by this means communication could be established The tests were made at the Bureau s experimental mine in Pennsylvania Vertical antennæ were found to give the best results, but on the whole radio methods were found to be of little practical value A promising method discovered was to connect the source of electrical energy (two dry cells) between a point on one side and a point on the other side of the coal seam Some of the paths of current flow spread out to the surface and could be picked up by a telephone satisfactorily by choosing suitable earths It was found, however, that this 'roof to rail method was only practicable for the transmission of signals from the surface into the mine and was therefore only a half solution Tests made with a geophone—an instrument which converts the earth waves made by hammering on the rock into an air wave which is heard in the ear as sound—gave good results The simplicity of this method and of the requisite apparatus is greatly in its favour

TEXTILES AS INSULATORS —The usefulness of industrial research is well shown in an article by A C Walker on "Textiles as Insulators", which appears in the *Bell Laboratories Record* for April Silk has been used for many years for insulating conductors owing to its much higher insulation resistance than cheaper fibrous materials like cotton The fact that the insulation resistance of textiles is greatly diminished when moisture is absorbed, suggested that a research on the effect of moisture on textiles might discover methods of treating them which would improve their electrical properties It was found that the continued application of voltage sometimes increased the insulation resistance a hundredfold This was traced to the partial removal of electrolytic impurities The most significant evidence of the importance of electrolytic impurities in silk, wool, cotton, and other textiles is the great improvement in their electrical qualities due to thorough washing with water It was found that cotton washed with water from Lake Michigan had higher insulation resistance than cotton washed with distilled water in the laboratory A saturated solution of magnesium carbonate was then used with encouraging results Washing the cotton with a little calcium sulphate in it gave as satisfactory results as using water from the lake As a result of the research the insulation resistance of cotton can now be improved by simple washing processes to such an extent that its use as a substitute for unwashed silk for telephone cords has been approved It is estimated that for this purpose alone the annual saving effected in manufacturing costs to the Bell Company is about one hundred thousand pounds

EFFECT OF DRYING ON THE PROPERTIES OF BENZENE —The effect of intensive drying on the physical properties of benzene has been re investigated by Briscoe Peel and Robinson whose results are described in the *Journal of the Chemical Society* for March Baker s previous conclusion that the density of benzene does not change upon drying has been confirmed not only for the liquid as a whole but also for the various fractions obtainable by distillation After drying for sixteen months there did not appear to be any definite change in the surface tension, and any change that may have taken place would seem to be in the direction of a decrease Baker, however, found a considerable increase after a year s drying and attributed it to a change in the degree of association The reason for this discrepancy is not apparent and the experiments are being continued

CHEMICAL APPARATUS —Messrs Griffin and Tatlock, Ltd , have issued their new catalogue of chemical apparatus, No 12A, as an attractive and well illustrated volume of close on a thousand pages The firm, which combines the former businesses of J J Griffin and Sons, Ltd , and Baird and Tatlock, Ltd , is established in London, Glasgow, Manchester, Edinburgh, and Liverpool The volume is divided into 12 sections which are further classified for convenience in the list of contents The usual fittings and furniture of chemistry laboratories are illustrated not only with pictures but also with model plans and sections A special feature of the Balance Section is the Christian Becker chainomatic balance, the action of which is fully described In the section for physical chemistry will be found apparatus for measuring osmosis, surface tension, etc , and also pyrometers and various kinds of electrical appliances A section on micro analysis opens with references to standard works where complete descriptions of methods of work will be found The apparatus is specially designed for the methods of Pregl and Dubský A large selection of the well known Reichert microscopes is minutely described in the optical section, which also includes refractometers, spectrometers and polarimeters with various accessories, as well as optical benches, mercury vapour lamps, selenium cells, etc , and the Bausch and Lomb projection apparatus for which the firm acts as sole agent Meteorological appliances, laboratory machinery, and apparatus designed for the special methods of assaying used in many different industrial processes form a prominent feature of the catalogue At the end there is a fairly long list of chemical and technical books and of Kahlbaum's pure chemicals

Systematic Investigation of the Oceans

AN international oceanographic conference was held in May 1928 in Berlin to commemorate the centenary of the Gesellschaft fur Erdkunde, which has published a series of papers dealing with recent and imminent expeditions[1] Most of these naturally deal with the results obtained by the *Meteor*, but articles also describe the work of the *Carnegie*, of the little Norwegian auxiliary ketch *Armauer Hansen* in the north east Atlantic, and the aims of the new Dutch Expedition to the East Indies in the *Willebrord Snellius*

As these articles are for the most part summaries of methods used and results achieved, they cannot be condensed into a short review, but the following notes on various points in this symposium may be of general interest

Numerous samples of sea water collected by the *Meteor* in the Atlantic were analysed for gold by the method due to Haber, whereby the gold in the water is adsorbed on a precipitate of lead sulphide which on heating with lead formate and boric acid leaves a minute bead of gold This is picked out from the crucible and measured under the microscope

An ingenious method was used to collect the small amount of lead sulphide, about 40 milligrams in each litre of sea water The full flask was inverted over a crucible also containing water and the whole spun in a centrifuge, when the lead sulphide collected at the bottom of the crucible To prevent loss of water in handling, the top of the crucible was covered with a rubber cap

The plankton rich upper layers were found to be richer in gold than the water below, much of this being adsorbed on, or contained in, the organisms The quantity varied from about $\frac{1}{100}$th milligram of gold per cubic metre to a third of this amount, or less in the deep water

The greater part of the scientific work of the *Meteor* centred around depth and physical measurements, from which to deduce the oceanic circulation from the internal field of force produced by differences in density, from the general distribution of salinity, and from direct current measurements For the first time these were successfully made from a ship at anchor in mid Atlantic where the depth was over 4 kilometres For this purpose stocked anchors weighing a quarter of a ton and a tapered wire cable 7½ kilometres long were carried The circumference of the wire cable at the anchor end was 3 6 cm and at the end made fast to the winch 5 cm

The temperature measurements at various depths were made with reversing thermometers, every pre caution being taken to attain the greatest possible accuracy In order to avoid error in reading due to parallax—a matter of very real difficulty on board a small ship in rough weather—the thermometer tubes were ground semicircular in section, with the bores close to the flat face upon which the graduations were marked The readings were carried to the third place of decimals, the graduation being in 0 05°

Only general conclusions regarding circulation in the Atlantic have yet been published, the mass of data and calculation for the application of Bjerknes' theory is in process of being worked up

An account of the biological survey by E Hentschel includes a chart showing the number of plankton organisms present per litre of surface water (Fig 1)

The effect of water rising from below and bringing nutrient salts to the upper layers, where there is sufficient light for plant growth, is clearly shown along the west coast of Africa The same effect is also shown in lower latitudes due to convection currents and unrestrained turbulent motion unchecked by a discontinuity layer

The chemical observations by H Wattenberg are of particular interest The distribution of phosphates and nitrates and the relation of these nutrient salts to the density of plankton in the south Atlantic confirm and extend previous investigations in more limited areas The distribution of dissolved oxygen was found to be regular and to reflect the circulation in the deep water, saturated cold water falling in high alti-

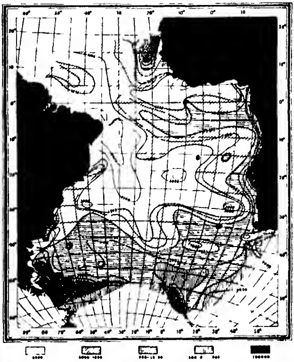

FIG 1—Plankton content of the surface water of the Atlantic, showing number of organisms per litre of water From Verhandlung der ozeanographischen Konferenz

tudes and filling the depths of the oceans, overlaid by water layers of less oxygen content in lower latitudes The minimum occurs at about 200 metres in the tropics, where a relatively thin warm and light layer lies like oil on the heavier water below, mixing by convection is hindered, and the supply of oxygen is cut off from above This minimum layer appears to be the graveyard of plankton organisms where oxygen is used up during their decay The presence of 5 to 6 c c of oxygen per litre in the deep water of the oceans indicates its origin in those latitudes where the surface water is at a temperature where more oxygen is needed for saturation, and where in winter convection currents can extend deep into the sea

The distribution of dissolved calcium carbonate in the sea is peculiar In the upper water layers of the tropics values indicating 50 per cent over saturation are indicated, below this the main mass of water is under saturated, less so near the bottom, where calcium carbonate is apparently dissolving out from the calcareous skeletons of dead organisms The actual quantity of calcium in solution, however, is considerably less in the upper layers, where it is utilised to build up the skeletons of such organisms

Closed Carbon Chains in Organic Chemistry

PROF W H PERKIN chose 'The Early History of the Synthesis of Closed Carbon Chains" as the subject of the first Pedler lecture, which he delivered before the Chemical Society on May 30 It was he said, very difficult to appreciate the fact that not more than fifty years ago the idea was firmly fixed in the minds of chemists that organic compounds must be sharply divided into the group having open carbon chains and the group having six membered rings The lecturer gave an interesting account of his discussions as a young student, with Victor Meyer and Baeyer regarding the possibility of preparing compounds containing rings composed of three, four or five carbon atoms and of his resolve to prosecute researches in that direction

The first step consisted in the condensation of trimethylene bromide with the sodium derivative of acetoacetic ester followed by hydrolysis whereby a product then believed to be acetyltetramethylene carboxylic acid but afterwards shown to be methyldihydrohexonecarboxylic acid, was obtained Before the erroneous interpretation had been corrected however the new method was vigorously developed in various directions, a substance which, indeed, proved to be tetramethylenecarboxylic acid being obtained in 1883 by the action of trimethylene bromide on the sodium derivative of malonic acid, followed by hydrolysis and elimination of carbon dioxide

Two years previously Markownikoff and Krestownikoff had obtained an acid which the lecturer and E Haworth afterwards proved to be *trans* tetramethylene 1 3 dicarboxylic acid, it was remarkable that this earlier observation attracted little attention at the time, and remained undeveloped Experiments on the action of ethylene bromide in place of trimethylene bromide on the sodium derivatives of acetoacetic ester and malonic ester brought the lecturer into conflict with Fittig, who with his pupils was at that time investigating the conditions of formation and the properties of lactones Prof Perkin gave a brief account of the evidence which led to the recognition of the formation of acids derived from trimethylene

The next step was to devise a method for the preparation of a derivative of the five carbon ring Tetramethylene bromide was then unknown, but ten years later it was obtained accidentally during the preparation of pentamethylene bromide, on condensation with the sodium derivative of malonic ester it readily yielded pentamethylenedicarboxylic ester, this on hydrolysis and elimination of carbon dioxide affording the long sought pentamethylenecarboxylic acid Similarly, hexamethylenecarboxylic acid was synthesised from pentamethylene bromide, and was shown to be identical with hexahydrobenzoic acid resulting from the reduction of benzoic acid In the meantime, an alternative method for the synthesis of the five carbon ring had been devised in 1885, the disodium derivative of pentanetetracarboxylic ester was treated with bromine, the resulting pentamethylenetetracarboxylic ester then affording pentamethylene 1 2 dicarboxylic acid The demonstration of the stability of the five carbon ring confirmed the views which Baeyer had, but a few months previously developed in his Spannungstheorie'

Finally, the lecturer referred to the syntheses of hydrindene and tetrahydronaphthalene, published conjointly with Baeyer in 1884 Interaction between *o* xylylene bromide (which proved troublesome on account of its severe effect on the eyes) and malonic ester proceeded exactly as Baeyer predicted

---

The Fauna of Scotland during the Ice Age.

IN his recently published presidential address to the Royal Physical Society of Edinburgh (*Proc*, vol 21 Part 4, February 1929) Dr James Ritchie discussed the Ice Age in Scotland in its faunistic bearings While Scotland must have shared in some degree the fluctuations of climate which have left traces so marked on the neighbouring shores of continental Europe, the earlier fluctuations either left no material remains or these have been removed by subsequent glaciation, for there is no faunistic evidence of the long series of changes which represents the early ice age or *altdiluvium* of continental geologists The Scottish Ice Age exhibits but a relatively short section of the Pleistocene glacial epoch

The remains of early glacial animals in Scotland are extraordinarily scanty, but they belong to the most important of all the animals as indicators of the period of their sojourn—the mammoth, the woolly rhinoceros, and the reindeer The association of these three animals indicates a period corresponding to the Third Terrace of the Thames Valley The mammoth and reindeer remains of Kilmaurs were overlaid by an extensive deposit of boulder clay, indicating conditions of ice covered land in which even such sub arctic animals could not have survived Their appearance in Scotland therefore must date to a preceding warmer period which was followed by a major glaciation

The known distribution of the mammoth in Scotland extends from Berwickshire through Mid lothian to Lanarkshire and Ayrshire Northward migration of the mammoth may have been prevented by a water barrier formed by the junction of the estuaries of the Forth and Clyde Such a condition in the midland valley would be accounted for by a relatively slight subsidence of the land Representative animals of the later glacial faunas have been found in Scotland only in isolated spots, with the exception of the fairly extensive faunas first discovered by Drs Peach and Horne in limestone caves near Inchnadamph, now being further explored by Dr Ritchie, Mr J E Cree, and Mr J G Callander

The oldest fauna so far discovered appeared after the cave riddled hill, more than 1000 feet above sea-level, had been set free from an ice cap which left enormous deposits of silt in the inner cave, and is an arctic fauna containing scarce remains of reindeer, many arctic rodents, the arctic wolf, lynx, and a very large bear A considerable period must have elapsed before the second fauna made its appearance, when the animal remains became involved in streams flowing off the valley glacier this fauna was predominatingly a reindeer fauna, remains of more than 400 individual reindeer having been discovered in a single cave of relatively small size There *is* no trace here of modern Scottish animals These appear in a higher layer which contains for the first time remains of red deer and, on account of the skeletal character and mode of burial of human remains in it, may be regarded as belonging to the period of Azilian culture, between the Palæolithic and Neolithic Ages.

University and Educational Intelligence

BIRMINGHAM.—The Mason chair of botany made vacant by the death of Prof. R. H. Yapp, has been filled by the appointment of Prof. Walter Stiles, professor of botany in the University of Reading. Prof. Stiles is well known for his work in plant physiology and on the cold storage of food. He has made numerous contributions to knowledge of cell permeability and photosynthesis.

CAMBRIDGE.—J. C. Burkill, Peterhouse, and P. A. M. Dirac, St. John's, have been appointed university lecturers in mathematics.

G. Anrep has been reappointed university lecturer in physiology, and H. Banister lecturer in experimental psychology.

R. A. Webb has been reappointed demonstrator in pathology and H. E. Tunnicliffe demonstrator in physiology.

The Council of the Senate recommends the adoption of the following regulations for the A. W. Scott fund:

I. The money received from the bequest of Prof. A. W. Scott for the furtherance of physical science shall be separately invested and shall constitute a fund called the A. W. Scott fund.

II. The income of the fund shall be applied as follows:

1. A short course of annual lectures shall be instituted in the physics department, and a sum of £100 shall be paid to the lecturer.

2. The head of the department may make grants, not exceeding a total of £150 in any financial year, to necessitous research students working in the Cavendish Laboratory.

3. A sum of £50 shall be retained in the fund each year, and money so accumulated may at any time be used by the head of the department in defraying the expenses of occasional small scientific conferences to be held in the laboratory.

4. The remaining income of the fund shall be paid into the departmental fund of the Cavendish Laboratory for general purposes.

The Rouse Ball studentship at Trinity College, founded for the purpose of enabling a student to study mathematics or the application of mathematics in a foreign university or school, has been awarded to W. R. Andrews.

On June 4 honorary degrees were conferred upon Sir Kynaston Studd (Lord Mayor of London), Prof. Langevin, Sir Frank Dyson (the Astronomer Royal), and Prof. Beazley.

The Appointments Committee of the Faculty of Agriculture and Forestry will shortly proceed to appoint (1) a university lecturer in agriculture to give instruction in crop husbandry, and (2) a university lecturer (Gurney lecturer) in forestry to give instruction in forest botany. Particulars may be obtained from Prof. T. B. Wood, Department of Agriculture, University of Cambridge.

LEEDS.—The Senate has awarded the degree of doctor of science to Mr. J. H. Birkinshaw and Mr. A. J. V. Underwood. Mr. Birkinshaw's thesis was entitled "Studies in the bio-chemistry of micro-organisms"; Mr. Underwood submitted a series of papers under the general title of "The application of mathematical methods to some engineering problems".

LONDON.—The degree of D.Litt. has been conferred on Dr. F. A. P. Aveling, University reader in psychology, for a Thesis entitled "The Psychological Approach to Reality".

Prof. John Coatman has been appointed as from Aug. 1, 1929, to the University Chair of Imperial Economic Relations tenable at the London School of Economics.

Calendar of Patent Records

June 17, 1783.—John Fischer, mechanic, of London, is the first patentee of a pedometer, his patent, sealed on June 17, 1783, being for "a geometrical and pedometrical watch which not only answers the purposes of a common watch, but is also distinguished by showing on the dial every step the walker makes and by measuring the distance". A combined pedometer and watch of this type made a few years later, but not by Fischer, is in the South Kensington Museum.

June 18, 1823.—Great economy and improvement in the bleaching industry resulted from the patent granted to William Southworth for a machine to hang out wet fabric in the tenter house and take it up when dry, the specification of which was enrolled on June 18, 1823. This was the first successful application of machinery to this purpose, and the invention was widely adopted. The life of the patent was prolonged for five years from 1837 in the name of E. Haworth.

June 18, 1849.—The Bourdon pressure gauge derives its name from Eugene Bourdon, who obtained a French patent for the instrument for fifteen years on June 18, 1849. An instrument acting on the same principle was invented about the same time by R. E. Schinz, a railway engineer of Cologne, as a gauge for locomotives, and was patented in Germany by C. J. Rahskopf, a watchmaker of Coblenz, in March of the same year. The rights in Bourdon's English patent were acquired by Messrs. Dewrance, of London.

June 20, 1801.—The lithographic printing process was patented on June 20, 1801, by Alois Senefelder, a native of Prague living in Germany. Senefelder brought the art to great perfection, and in 1818 published instructions for using it.

June 20, 1840.—Samuel Morse patented his electric telegraph system in the United States on June 20, 1840, and the first commercial telegraph was opened between Baltimore and Washington in 1844.

June 21, 1889.—To William Friese Greene, a London photographer, must be awarded the honour of having first introduced a practical camera capable of taking an unlimited number of photographs in rapid sequence upon a band of sensitised celluloid film and suitable for subsequent reproduction in the form of a moving picture. His patent was taken out in conjunction with Mortimer Evans and is dated June 21, 1889. The first moving picture taken by Friese Greene was that of the traffic at Hyde Park corner, and it was shown on the screen at a meeting of the Royal Photographic Society in 1890.

June 22, 1839.—On June 22, 1839, Abel Morrall, a needle maker of Studeley, was granted a patent for burnishing the eyes of needles by threading them upon a roughened steel wire stretched in a frame and caused to revolve or to move backwards and forwards. The needles are thus made to vibrate upon the wire, and the eyes are very effectively smoothed. Up to that time there was no method of making the elongated eyes smooth, and the patent, which was acquired by Messrs. Bartlett of Redditch, became a very valuable one.

June 22, 1906.—Low temperature carbonisation of coal and the production thereby of a smokeless fuel dates from the work of Thomas Parker, engineer, of Wolverhampton, who patented his process on June 22, 1906, and introduced the new fuel to the public under the name of "Coalite". Plants were erected at Plymouth gas works and later at Barking, but commercial success was not at that time achieved, and it has required many years of research to make coalite a marketable product.

Societies and Academies

LONDON

Geological Society, May 8.—F. M. Trotter: The glaciation of eastern Edenside, the Alston Block, and the Carlisle Plain. Three glaciations separated by intervals have been recognised. The ice of the first or Scottish glaciation deployed from the Southern Uplands, swept across the Carlisle Plain, one stream continuing eastwards, the other advancing up Edenside, where it was joined by a stream from the Lake District. Exposures of the ground moraine of this glaciation are rare, and in eastern Edenside the moraine is in places overlaid by a series of contorted laminated clays, etc. These clays are in turn overlaid by the drifts of the second or main glaciation, when eastern Edenside was occupied by Lake District ice and Cross Fell ice. Because of the presence of Scottish ice on the north and ice from Howgill and Wild Boar Fells on the south, Edenside became congested with ice. The surface level of the ice rose to 2200 feet at least, and probably higher. The retreat of the ice front after the maximum of the main glaciation can be traced stage by stage. The last glaciation was the renewed advance of the Scottish ice across the Carlisle plain, up to an altitude of 400 or 500 feet O.D. At its maximum extension, and during its retreat, this glacier dammed up glacier lakes which drained south-westwards.—J. A. Douglas: A marine Triassic fauna from eastern Persia. An account of the discovery by Mr. R. C. Jennings and Mr. K. Washington Gray, geologists of the Anglo-Persian Oil Co., of a marine Triassic fauna in the district of Naiband. Comparison with other Triassic outcrops suggests an extension of the Triassic Tethys into Persia in Carnic times, and again at a later stage, in the Rhætic period. During the intervening Noric epoch, however, communication with the Mediterranean province was severed, while species characteristic of the Trias of the East Indies make their appearance in great numbers. There is little evidence for migration having taken place between the two areas along the 'Himalayan route' and it is suggested that the continental barrier of Gondwanaland was breaking up into an archipelago of islands.

Royal Meteorological Society, May 15.—J. Edmund Clark, I. D. Margary, R. Marshall, and C. J. P. Cave: Report on the phenological observations in the British Isles, December 1927 to November 1928. The year 1928, considered as a whole, differed but slightly from the average for 35 years. We think of the year as sunny, but the dull spring balanced brilliancy in January, July, and September; so, too, the bitter December and chilly June were offset by the wonderful warmth from January to April, with only occasional slices of cold. December checked the hazel, despite January, making it flower at the average date; coltsfoot came early. The horse chestnut flowered two days instead of six earlier than the hawthorn. Migrants, despite some remarkable premature records of swallow, chiffchaff, and cuckoo, averaged only a couple of days early. But this fully suffices to make the lines of equal appearance dates (isophenes) shift markedly northwards compared with 1927.—D. Brunt: The index of refraction of damp air, and the optical determination of lapse rate. The correction to the index of refraction to allow for the presence of water vapour is given. Variations of humidity give results which cannot be distinguished optically from variations of temperature.—J. Reginald Ashworth: The influence of smoke and hot gases from factory chimneys on rainfall. In a manufacturing town such as Rochdale, the combustion of large quantities of coal must produce an upward current of hot air which is probably sufficient to influence the rainfall. The variation of the rate at which rain falls agrees very closely with the fluctuation of smoke emission as tested by the average number of soot particles deposited from the air each day of the week.

DUBLIN

Royal Dublin Society, May 28.—J. Joly: Bi-radiant needles for use in the radioactive treatment of tumours. These needles, like those developed by the author in collaboration with Dr. Walter Stevenson in 1914, are hollow, so as to contain radium or its emanation. They are, however, divided vertically into half-needles differing in density or thickness so that rays issuing from opposite sides of the needle are unequally screened. It is therefore possible to control the intensity of radiation in different directions. Thus the natural selective effect which is believed to be responsible for the success of radio-therapy, may be enhanced by the orientation of the needles; the surrounding healthy tissues receiving definitely weaker radiation than the body of the tumour. Details respecting security against rotational movements of the needle when *in situ*, their various forms, and mode of construction are given.—W. R. G. Atkins and H. H. Poole: (1) Photo-electric measurements of illumination in relation to plant distribution. Pt. 2. Using portable galvanometers and blue-sensitive vacuum sodium photo-electric cells of the Burt type measurements were made of the daylight factor (δ) at various points in a garden; δ may be as low as 1.3 per cent under laurel bushes and holly, where only ivy straggles. *Scolopendrium vulgare* may thrive with $\delta = 2.2$ per cent. (2) The photo-electric standardisation of an uranyl oxalate method of daylight photometry. By exposing 10 c.c. of solution in six-inch quartz tubes it was found that from 0.183 to 0.236 c.c. of N/10 oxalate was destroyed per thousand metre candles per hour. The illumination was measured by a Burt cell. In noon July sunlight 85 mg. oxalic acid may be destroyed per hour, and the daily variation in this rate was studied. (3) The photo-chemical and photo-electric measurement of the radiation from a mercury vapour lamp. The uranyl oxalate method, the fading of methylene blue, the production of nitrite, and the Burt sodium cell were used, in conjunction with erythema tests, to measure the radiation from a quartz lamp. By means of various screens it was shown that what the cell measures may be taken as an index of the therapeutic value of the radiation. The intensity reaches a minimum one minute after the arc has struck and reaches a roughly constant value, fifteen times as great, five minutes later.

PARIS

Academy of Sciences, May 6.—The president announced the death of Dr. Trabut, *correspondant* for the Section of Rural Economy.—L. Cayeux: The conditions of the Silurian sea with Graptolites in Normandy. A study of the upper Silurian as revealed by a deep boring made at Danneville, Calvados, in a search for iron ore. The Graptolite Gothlandian of Normandy offers strong evidence in favour of a phenomenon of lagunar evaporation, leading to the formation of a bed of gypsum.—Charles Richet and Mme. L. Braumann: The accelerating action of minute amounts of lanthanum salts on fermentation. The amount of acid produced by the lactic ferment is increased by amounts of lanthanum sulphate of the order of 10^{-8} grams per litre.—Gabriel Bertrand and Mlle. C. Voronca-Spirt: Titanium in phanerogam plants. Titanium is met with in all phanerogams, the

green parts, especially the leaves, containing the highest proportion of the metal Titanium has been found in plants by other workers, but its presence has been ascribed to the accidental presence of dust Precautions against such contamination have been taken —**J B Charcot** The South American Antarctic A statement of the results of French explorations, especially those of Dumont d'Urville —**Léon Guillet and Michel Samsoen** Studies of traction at high temperatures A description, with illustrations, of the arrangement of test pieces and furnace, the latter automatically controlled within 3° of 450° C Figures are given for the elastic limits of four steels —**E Mathias** Contribution to the study of fulminating matter its explosion by shock Historical summary of cases of globular lightning —**Charles Nicolle, Charles Anderson, and Pierre Hornus** A new spirochæte from a case of recurrent Moroccan fever A discussion of the relations between the spirochætes of Spain, Mansouria, and the new organism, based on the agglutination effects and partial immunities —**Constant Lurquin** The forms of extension of the Bienaymé Tchebycheff criterion —**J Favard** What is the smallest circle in the interior of which can be put all the plane convex curves of length L and surface S ?—**Bertrand Gambier** Groups of transformation and geometrical theorems —**Georges Giraud** The generalised problem of Dirichlet, complements relating to the linear case and to the non linear case —**A Angelesco** Certain polynomials of Tchebycheff —**Rolf Nevanlinna** A problem of interpolation —**R Chambaud** The bending of rectilinear pieces submitted to an eccentric force of compression —**D Wolkowitsch** A new type of spring —**P Biquard** The phenomena produced by the interposition of a metallic plate in a bundle of ultra sound waves —**Henri Chaumat** A comparison between electro static machines and direct current dynamo machines —**Henri Gutton** The dielectric constant of ionised gases —**L Bouchet** The electrolytic potentials of some metals Results of measurements of the electrolytic potential, referred to the normal calomel electrode taken as zero, are given for magnesium, zinc, hydrogen, copper, and silver —**Mlle A Serres** The magnetic properties of ferric oxide and of some ferrites above their Curie point, conservation of constant paramagnetism in these combinations —**Robert Forrer** The two Curie points, ferromagnetic and paramagnetic To obtain spontaneous magnetisation, the existence of a magnetic moment and a spontaneous orientation is not sufficient, there must be hysteresis in addition Ferromagnetism only exists below the two Curie points —**A Couder** Description of the diffraction figure at the mean focus of an astigmatic bundle —**E Sevin** The theories of the continuous X spectrum and of Compton's phenomenon Remarks on a recent communication of Décombe on the same subject —**Jean Jacques Trillat** The phenomena of orientation and of pseudo crystallisation resulting from the effect of traction in colloidal gels Results obtained by the application of X ray photography to nitrocellulose or cellulose acetate films under varying amounts of stretching —**C Pawlowski** The production of the H-disintegration rays under the α radiation of polonium The α rays of polonium are, as Schmidt has shown, capable of producing the disintegration of aluminium The H_α rays can be produced not only by α rays of a path of 3 9 cm but also by those of a path of 2 4 cm —**E Cornec, H Krombach, and A Spack** The equilibria between water and the nitrates and sulphates of sodium and potassium —**P Lebeau and A Damiens**: A new method of preparing fluoride of oxygen —**Ch Bedel** The solubility of silicon in hydrofluoric acid The variations in the solubility of silicon in hydrofluoric acid have been attributed to the state of division of the former, the experiments detailed in the present paper do not confirm this, the most important factor in the attack being the concentration of the acid —**Mlle M Cabanac** The hydrogenation of the acetals of the fatty acids The reaction is

$$CH_3\ CH(OR)_2 + H_2 = C_2H_5\ O\ R + ROH,$$

and appears to be general It constitutes a method of preparing either symmetrical or mixed ethers —**D Ivanoff** The thermal decomposition of the organo magnesium alcoholates —**Y Milon** The existence of a marine Eocene formation in the depression of Toulven (Finistère) **Bruet** A particular facies of the upper Pleocene of the valley of the Aujon (Haute Marne) —**G Delamare and C Gatti** *Indiella americana*, a hyphomycete capable of cultivation —**Jules Amar** The pulmonary *tirage* This term is applied to the expression $\pi h/p$, where π is the perimeter taken round the level of the breasts h the height of the bust, and p the weight of the body This has an average value of 124 for men and 108 for women —**Emile F Terroine and Mlle Thérèse Reichert** The influence of the salt ration on the magnitude of the nitrogen retention in the course of growth It has been shown in an earlier communication that the presence of a complex mineral ration (common salt, potassium chloride, potassium phosphate) considerably increased nitrogen retention during growth It is now shown that the constituents of the saline mixture taken singly, exert no favourable action —**E Voisenet** Divinylglycol considered as the cause of the bitter taste in the disease of bitter wine From a sample of Burgundy attacked by the disease a liquid has been isolated with a very bitter taste It has been identified as divinylglycol, $CH_2 - CH - CH(OH) - CH(OH) - CH = CH_2$ —**Georges Blanc and J Caminopetros** The duration of conservation of the virus of dengue in the Stegomyas The influence of the cold season in the infecting power It has been shown that dengue is transmitted in Greece by the mosquito *Stegomya fasciata* The infected mosquitoes can live under favourable conditions at least 200 days They lose their infecting power when the mean temperature falls below 18° C, but the virus is not destroyed, since the Stegomyas again become infectious when the temperature rises above 18° C This mosquito can thus carry the infection from one year to the next

The British Patent System

ON a number of occasions in recent years attention has been directed in these columns to the importance of the British patent system from the point of view of scientific men and we have pointed out that the defects from which it suffers, whether in respect of law or of administrative machinery, ought to receive more serious consideration from the Government of the day than they have until recently obtained It has therefore been particularly gratifying to note a number of indications that the importance of this branch of the public service is coming to be recognised more adequately One of the pleasantest of these indications was the conferment in the birthday honours list, of a knighthood on the Comptroller General of Patents Mr W S Jarratt whose appointment a few years ago gave much satisfaction to those who had been contending that scientific and technical qualifications were essential to the adequate discharge of the Comptroller s duties

The report recently issued by the British Science Guild on the subject of the reform of the patent system has received general support from the Press and from a large number of interested bodies but perhaps the most interesting comments yet made upon it are those that have just been issued by the General Council of the Bar, which appointed, some time ago, an extremely strong committee to review the British Science Guild report The committee included, among others, Sir Duncan Kerly, K C (chairman) Mr James Whitehead K C, the Hon Stafford Cripps, K C, and Mr Trevor Watson, the members agree that the report of the British Science Guild ' is generally excellent, and that most of its proposals are reasonable and likely to be useful " They then discuss certain of its paragraphs in detail

The committee agrees strongly that the effect of paper anticipations ' should be restricted, that remedies against unwarranted threats should be strengthened, and that appeals from the decisions of the Comptroller of Patents should be heard by a special judge in chambers instead of by the Attorney General or Solicitor General as at present The only proposals in respect of which the committee is opposed to the Guild s recommendations are those which would extend the judicial duties of the Comptroller It thinks that the object of these proposals—namely, the mitigation of the present high cost of patent litigation—would be better achieved by (1) resort to arbitration or (2) agreement between the parties whereby the issues to be

tried in court may be narrowed down The latter of these alternatives commends itself strongly to common sense, but the former presents difficulties In a highly technical industry it is often far from easy to find an expert whose interests are entirely independent of those of the parties, and it is very much more difficult to find such an expert possessed of the additional qualification of experience in the construing of patent specifications

The recent appointment by the Board of Trade of a departmental committee, under the chairmanship of Sir Charles (formerly Lord Justice) Sargant, to consider the subjects dealt with by the British Science Guild's report, has brought the proposals for reform within the realm of practical politics These proposals have five principal aims (1) To diminish the grant of invalid patents , (2) to relieve the main patent system of the monopolies for small innovations which may be regarded as useful designs rather than inventions, and are protected in Germany by *Gebrauchsmuster* , (3) to mitigate the evils arising from the high cost of litigation , (4) to render more accessible to the public the information which is in the possession of the Patent Office , and (5) to improve in detail the efficiency of the patent system

The procedure to be adopted by the Sargant Committee has now been decided, and it appears that evidence will be received from persons having a suitable *locus standi* It is to be hoped, therefore, that the manufacturers and others whom the subject concerns will make themselves familiar with the proposals which have been put forward, in order that a widely representative body of reasoned opinion may be available to the new committee It is gratifying to know that many organised bodies have, like the General Council of the Bar, appointed responsible committees to examine the matter from the points of view which they represent, and that at its recent meeting the Council of the British Association resolved to support the recommendations of the British Science Guild

The growing importance of the patent system is indicated by the statistics disclosed in the Patent Office Report for 1928, which was published on May 31 last The volume of patent business shows a rapid increase, the number of complete specifications filed during the year, namely, 24,045, being greater by 2648 than that for the previous year The number of letters dispatched increased from 314,000 in 1927 to 331,000 in 1928, the number of patent specifications sold from 370,808 to 424,028, and the number of applications under the International Convention from 6810 to 7971 The amount received from renewal fees increased by only £5767 to a total of £283,252, but somewhat larger increases may be expected under this head as the effect of the War period passes away

It is remarkable that during the same period the total strength of the staff increased only from 696 to 698, while the strength of the examining staff increased by only 4 to a total of 240 The staffing question is a very grave one, for not only is the work of the Patent Office dangerously in arrear, but also the utmost difficulty is likely to be experienced in obtaining any additional examiners who may be required to implement the recommendations of the Sargant Committee A competitive examination for technical posts in the Patent Office was held last year and failed to attract candidates further, the cream of the examining staff is constantly being skimmed away by the offer of more lucrative appointments in industry The problem of obtaining and keeping properly qualified recruits is one of the most urgent of those which call for early solution It is not satisfactory that officials who to day are entrusted with highly confidential information, should to morrow be working for rival firms in whose employment their knowledge may be embarrassing

On the other hand, there should be no difficulty in financing considerable improvements in the machinery of the patent system without recourse to the public purse, for the annual surplus of fees over expenditure has reached the very large amount of £147,840 out of a total revenue of £544,740 , and to this surplus should properly be added the cost of maintaining the Patent Office Library, which is used by the general public and cannot be regarded as the exclusive concern of patentees The following table is of interest in this connexion

Year	Complete Specifications Filed	Surplus £	Strength of Examining Staff
1924	18,800	75,202	253
1925	19,434	88,540	241
1926	19,948	98,813	238
1927	21,397	112,939	236
1928	24,045	147,840	240

On the whole, it may be said that there is a better prospect now than at any other time during the past twenty five years of bringing the patent law and machinery up-to date The co operation of all who have serious contributions to make will be needed if full advantage is to be taken of the opportunity which has presented itself

The Beginnings of Entomology

Materialien zur Geschichte der Entomologie bis Linné Von Dr F S Bodenheimer Band 1 Pp x+497+24 Tafeln (Berlin W Junk, 1928) 2 vols, £6

ENTOMOLOGY has been called the Cinderella of the sciences If the study of insects has for long played the part of neglected sister among kindred pursuits, it cannot be denied that of late years it has held a position second to none in respect of its bionomic, economic, and hygienic importance Entomological history is, however, poor in comprehensive treatises This is remarked by Dr Bodenheimer at the outset of the present work, which, though modestly entitled ' Materials for the History of Entomology ", and stated by him to aim only at a survey, not an exhaustive presentation, is a monument of careful and industrious research, and goes far towards repairing the deficiency to which he directs attention

The earliest entomology was utilitarian, the production of silk and of wax engaged the attention of the most ancient civilised races, to the exclusion of any matter of biological interest According to Chinese tradition, silk cultivation, for the sake of clothing and of religious ceremonial, goes back to the Emperor Fu hsi at the beginning of the third millennium B C The secret of silk production was rigidly kept throughout many ages, but within comparatively recent times illustrated works, professedly based on earlier treatises, have been issued by the Chinese, giving details of the whole process Some interest in natural history is evinced by late editions of the Erh ya, an encyclopædia attributed in its original form to a writer of the sixth century B C Recognisable figures of the dung beetle, wood boring larvæ, the cicada, mantis, and mole cricket are reproduced by Dr Bodenheimer from this work

To the ancient Egyptians, as to the Chinese, the appeal of entomology was mainly utilitarian, though bees, and possibly wasps, appear as symbols so early as the period of the First Dynasty A relief from the temple of Ne user re (about 2600 B C) shows the process of extracting honey from combs after fumigation, of refining, and of sealing it in a permanent receptacle Representations of butterflies are found among Egyptian wall paintings, some of which may almost certainly be identified as *Danaida chrysippus* Egyptian pharmacology contains recipes in which insects take part, while the " Book of the Dead " has many references to insects The interest taken in the scarabæus as an emblem of the sun-god is well known, it does not appear, however, that the Egyptians were acquainted with its metamorphoses Herodotus in his book about Egypt mentions the use of mosquito curtains

Little is known of the entomology of Assyria and Babylon, but there is a cuneiform record of the importation into Assyria and acclimatisation of bees for honey and wax, sculptures and seals of these nations present good figures of flies, and of locusts preserved for food The inhabitants of Palestine were interested in insects chiefly for their useful, noxious or troublesome qualities Besides locusts, the raids of which are so vividly described by the prophet Joel, there are references in Isaiah to the ravages of the clothes moth, honey seems to have been known to the Israelites only from wild bees In later times the Talmud contains natural history items of interest

It is remarkable that among the earliest relics of European civilisation occurs the symbolising of the soul under the figure of Psyche, or the butterfly A striking reproduction of a Mycenean wall painting is given by Dr Bodenheimer, in which the death goddess, walking in a field of asphodel, is surrounded by fluttering butterflies With Homer we enter upon a new period His likening of the opposed ranks of Greeks and Trojans to swarming flies, and his similes derived from bees, wasps, cicadas, the gadfly, locusts, show powers of keen observation and poetic insight A passage in the Iliad proves that its author was aware that maggots of carrion were the offspring of the blowfly In Aristotle we meet the embodiment of Hellenic thoroughness, the principles of classification, the facts of anatomy, physiology, reproduction, metamorphosis, are minutely dealt with by him in relation to insects as to other forms of life Good natural history notes are to be found in his works, and on all these accounts the philosopher of Stagira well deserves to be known as the father of scientific entomology Among his successors, Theophrastus has valuable entomological observations, chiefly from the point of view of injury to vegetation, while Dioscorides regarded insects chiefly as ingredients in the Pharmacopœia But the biological interest started by Aristotle was never entirely lost His facts were incorporated in later treatises, and were amplified by Pliny, the eleventh book of whose ' Natural History ", devoted to insects, shows him to have been more than a mere compiler He, says our author, rather than Aristotle, gave the impulse to Gesner and Aldrovandi But the sober minded Romans generally went in for utility The entomology of Cato, Varro, Columella was of the ' economic ' variety, and even

Virgil's poetic and imaginative "Georgic" on bees had an ultimately utilitarian object.

With the advent of the Middle Ages the Hellenic love of observation and desire for scientific knowledge underwent a temporary eclipse. Such compilations as were produced tended rather to utilitarianism or to moral teaching. But from the beginning of the twelfth century may be roughly dated a revival of interest in Aristotle, preceded by Arabic influence which began to make itself felt at an even earlier date. Aristotelian science spread into western regions, especially Spain, through Arabs who derived it from Byzantium. A translation of Aristotle's zoological works into Arabic, with a commentary, had been made about A.D. 1000; much advance had also been effected by subsequent Arabic writers. A great name of this period is that of Albertus Magnus (1193-1280), Provincial of the Dominicans and Bishop of Regensburg, whose fine treatise "De Animalibus", with its faithful following of Aristotle, gained him the title of "Aristotle's Ape". The book shows evidence of original observation, and contains acute remarks on the relation of structure to function. The somewhat small portion devoted to insects, like the rest, is naturally not devoid of errors; but Dr. Bodenheimer is probably right in asserting that there is no greater biologist than Albertus between Aristotle and Réaumur.

The end of the fifteenth century witnessed the dawn of a new age in art and literature. The discovery of America, the general revival of Greek, the invention of printing and the rise of vernacular literature combined to set in motion a fresh impulse towards learning in general and the cultivation of science in particular which has gone on without a break to the present day. From this time natural science gradually disentangled itself from theological and medicinal limitations. It must be admitted that in the general revival entomology lagged somewhat behind. Its new age can scarcely be said to begin until Aldrovandi published in 1602 his "De Animalibus Insectis" in seven books, the result of fifty years' study, and the first work entirely devoted to entomology. His classification, founded on Aristotle, whose influence was still strong, is in some respects less in accordance with Nature than that of his master. But he remains a true Aristotelian, though a critic of that author's mistakes. His volumes contain excellent figures, especially of Lepidoptera, and also the first illustration of insect anatomy (the silk gland of *Bombyx mori*).

The English physician Mouffet (1530-1604) carried on and added to the compilations of Gesner and Wotton, of which he had received the drafts through Thomas Penn. Mouffet's figures of insects, which are mostly independent of Aldrovandi, are quite good. They were not published until 1634. Bacon made observations on insects, but had little or no direct influence on biological science; nor had his younger contemporary Descartes much interest in biology and its problems.

Harvey (1578-1657), who may be called with justice the founder of modern physiology, was the first of modern biologists to include invertebrates in his physiological researches. His wide conception of the 'ovum', which he took to include both larva and pupa, had the unfortunate result of leading to Swammerdam's theory of 'evolution', 'emboîtement', or preformation of the imago in the egg. Before the close of the seventeenth century Redi had disproved by experiment the theory of spontaneous generation which had held the field since Aristotle; Malpighi had published under the auspices of the Royal Society his elaborate work on the anatomy of the silkworm; and Swammerdam had executed the admirable insect dissections illustrated in his great "Bibel der Natur". A little later the pioneer microscopists Leeuwenhoek in Holland and Hooke in England had investigated and figured the compound eyes of insects, the histology of insect muscle, the structure and action of insect wings, and parthenogenesis in aphids. Goedart, a painter who took to entomology, and Lister, physician to Queen Anne, occupied themselves with the question of insect parasites. Lister was the first to establish the true life history of the parasitic wasps.

In 1705 Madame Merian published her finely illustrated work on the insects of Surinam. A little later came Vallisneri, who, in spite of his dictum that "Observation is better than Speculation", firmly supported Swammerdam's doctrine of 'evolution'. But the chief name for entomology at this period until the advent of Linnæus is certainly that of the versatile Réaumur, whose volumes of "Mémoires" contain most valuable studies in insect anatomy and physiology. The succession was carried on by Roesel and Bonnet; and before the end of the eighteenth century the binary system of nomenclature, towards which the previous work of Ray and Willughby had tended, was, in the hands of Linnæus, to make identification for the first time generally possible.

At this point the present instalment of Dr. Bodenheimer's exhaustive treatise is brought to a conclusion, leaving Linnæus and his successors to be dealt with in a future volume. Much commendation is due to the author for the way in which he has carried out his laborious undertaking, of which the

present article may be taken as virtually a summary The book is well produced and well illustrated The only printers' errors that have come to notice are a misplacement of reference letters on Plate VII, and " Bohart " for Bobart (the Keeper of the Botanic Garden at Oxford) on p 491

Modern Cosmogony

(1) *Astronomy and Cosmogony* By Sir James H Jeans Second edition Pp x+428 (Cambridge At the University Press, 1929) 31s 6d net

(2) *Eos or The Wider Aspects of Cosmogony* By Sir James Jeans (To day and To morrow Series) Pp 88+6 plates (London Kegan Paul and Co, Ltd, New York E P Dutton and Co, 1928) 2s 6d net

(3) *Cosmology a Text for Colleges* By Prof J A McWilliams Pp x+243 (New York The Macmillan Co, 1928) 10s 6d net

(1) THE publication, within a few months of a second edition of " Astronomy and Cosmogony ", replete with abstruse mathematical formulæ and priced at 31s 6d, is a noteworthy event on which Sir James Jeans may well be congratulated The demand for the book is a striking tribute to the clearness and wide appeal of the author's manner of exposition, as well as to the extent of his reputation as an authority on questions of cosmogony, for the present boom in matters astronomical, especially of the more speculative type, is by no means a sufficient explanation Naturally, within so short a time, no need has arisen for drastic alteration, although there has been more modification than the mere correction of minor errors and misprints The book has been expanded by references to various observational and theoretical results which have appeared since the first edition was written, and space has been allotted more liberally to certain problems and investigations " which ", says the author, " friendly critics thought I had dismissed too briefly in the original book " We note that among the problems and investigations thus referred to are some of those mentioned in the review of the first edition which appeared in NATURE of Aug 4, 1928 The new edition contains eight pages more than the old This is due almost entirely to additional matter, the amount of modification of the original text being negligible There is nothing that calls for special comment The former point of view is maintained without change, and the prospect it commands, though scanned in slightly greater detail in certain directions, preserves the same aspect Sir James Jeans's methods, as well as his conclusions, are highly original, and whatever may be thought of their validity, are singularly acute and penetrating It is too early yet to form an estimate of their final value, but we may say with confidence that no consideration of the subjects with which they deal can afford to neglect so important a contribution

(2) It was a happy idea of the editors of the ' To day and To morrow " series to pay some attention to Yesterday, and the choice of Sir James Jeans as historian could scarcely have been improved upon Readers of NATURE are familiar with the general character of the cosmogony which, during recent years, he has been engaged in constructing, and they will find here a clear and summary account of it in its most up to date form The book is based on the Trueman Wood lecture delivered before the Royal Society of Arts on Mar 7, 1928, and a lecture on " Recent Developments of Cosmical Physics " at the University of London on Nov 9, 1926 Both these lectures were reproduced in NATURE shortly after delivery The present volume, therefore, is to be recommended on account of its compactness rather than its novelty, and also for the illustrations of nebulæ and star clouds, of which six are excellently reproduced The book is less an argument than a description, leading, as all scientific work does, to more questions than it answers For the reasons which have led to the conclusions presented, the inquirer must be referred to Sir James Jeans's larger work on ' Astronomy and Cosmogony " It is necessary to say this because, taken alone, some of the statements appear to wear an air of confidence unjustified by the grounds on which they are based Whatever may be the reader's reaction to the views expressed, however, the reading of the book will be accompanied by unalloyed pleasure Sir James Jeans remarks that astronomy is a subject on which ' one could hardly be prosaic if one tried " We have received many proofs that this is an under estimate of human ingenuity, but if the remark be restricted to the present author we can give it whole hearted assent

(3) Prof McWilliams's book is described as " a text for colleges " Cosmology is not a subject with which we are familiar in college curricula, but it is clear from the treatment that the book is intended mainly for Roman Catholics, for the viewpoint of the Catholic Church is taken through

out It is impossible, therefore, for one who does not share that viewpoint to treat the discussion with much sympathy It does not appear to us, for example, that the author presents the most significant feature of the transition from Ptolemy to Copernicus in the following brief (and only) reference to the event " In the sixteenth century, Copernicus, a cleric and physician as well as astronomer, got out the system that is accepted to day thus was fulfilled the conjecture of St Thomas that some day another system might supplant the Ptolemaic " Apart from matters of prejudice, however, the reasoning is not of the kind which is likely to convince the scientific mind What, for example, are we to make of the following argument to prove that the assertion that the material universe is actually infinite in extent is contradictory in itself " ?—" In any *extension* we can conceive a part to be subtracted annihilated, or removed from consideration Now the remainder is either finite or infinite If finite, then that finite remainder plus the finite part removed equaled infinity, which is a contradiction If the remainder be infinite, then the void left by the part subtracted constitutes a limit to the infinite remainder, and by restoring the part we add to the actually infinite all of which is contradictory " We can only say that those to whom such arguments appeal will find here a systematically classified text book, each chapter of which contains a concisely worded thesis, arguments in favour thereof, a statement of possible objections with the replies thereto, and a list of references to other relevant literature The book is clearly written and well produced H D

Hurricanes in the West Indies

Los Huracanes en las Antillas Por Rev Simón Sarasola, S J Segunda edición, aumentada con el Apéndice Génesis y Evolución del Huracán de 20 de Octubre de 1926 y Catálogo de Ciclones en la Isla de Cuba de 1865 a 1926, por Rev Gutiérrez Lanza, S J Pp xv + 254 (Madrid Bruno del Amo, Habana 'La Moderna Poesía", 1928)

THE early appearance of a second edition of this useful treatise on the hurricanes of the West Indies by the Director of the Colombian Observatory at Bogota suggests that the work has already been found serviceable in that part of the globe

It appears that there is a suggestion of an English translation before long, which seems a highly desirable proposition in view of the number of British colonies in the West Indies Incidentally, such a translation would very considerably lighten the labours of an English reviewer who now asks the author's indulgence for any shortcomings resulting from unfamiliarity with Spanish

The treatise opens with a general account of the circulation of the atmosphere and the character of cyclones with a discussion of the different kinds of clouds illustrated by some good photographs, among which is a thundery cumulo nimbus of superb proportions It then goes on to the proper subject matter more specifically, dealing with the signs of approaching hurricanes, differences in their intensity and in the frequencies of the tracks they pursue in different months of the year It is shown how far European methods of forecasting storms based upon the principles of Bjerknes Guilbert Vercelli and others are locally applicable, and a considerable amount of space is given to the theory of tropical revolving storms The concluding part of the book discusses the correlation between hurricanes and sunspots and other indices of solar activity, but as usual in this field without any very decisive results

Tropical cyclones appear to make up for their greater violence by being distinctly less frequent than those of extra tropical latitudes, although a comparison is rendered difficult since there is no evidence of uniformity in the criteria adopted for defining a West Indies hurricane and a European gale A catalogue at the end of the volume shows that in the single island of Cuba, eighty five ' hurricanes ' of varying intensities occurred during the sixty two years, 1865–1926, giving an average of one or two a year whereas the number of ' general gales ' in the British Isles average about ten yearly

As in all other regions devastated by tropical storms, the West Indies suffer most in the later summer and autumn months Thus, out of 239 cyclones of varying intensities recorded in the West Indies between 1887 and 1923, May had 1, June 16, July 17, August 39, September 78, October 71, November 15, and December 7

The author presents a very impartial and open minded account of the vexed question of cyclonic genesis, and states his own views on the subject We should like to suggest that he might here have effected to advantage some unification of ideas Whereas he favours the view that the tropical disturbances arise from the encounter of opposing currents, he does not take kindly to Sir Napier Shaw's suggestion that polar front principles may be applicable in this region Now hurricanes in the West Indies, as in other tropical regions, occur

just at the time of year when the migrating trade wind system, having reached its farthest position across the equator is likely to be more heavily charged with moisture than the other trade system which it encounters Hence there is likely to be some kind of 'front' or 'discontinuity' in the trough of relatively low pressure between the interacting trades where the cyclones form and there is actual evidence that humidity 'fronts' in the doldrums may play a more important part in storm production than thermal fronts, which are so pronounced in temperate latitudes (See for example, C S Durst, *M O Geophys Mem*, No 28, 1926)

We think it should be better realised by writers on the theory of cyclones that there is nothing to warrant the assumption that these any more than other natural phenomena, are to be explained in terms of a single cause There must be various contributing collateral and sequential factors involved in the cause of cyclones

The appendix gives a vivid narrative of the dreadful cyclone that devastated Cuba in October 1926 The Meteorological Service issued timely warnings, and such measures as were practicable to lessen the number of fatalities were taken in the city of Habana and elsewhere It is quite clear that cyclones in the West Indies are taken very seriously, as well they might be A bad storm may take a day or two to pass over a district, may bring 10 to 20 or more inches of rain in twenty four hours, and wind blowing at the rate of 100 to 150 miles per hour There can be no question that when the area covered and time occupied by such violence of wind and rain are considered, the tropical cyclone must be regarded as the most formidable type of storm that occurs on this planet, with the possible exception of the great snow blizzards of colder climates

The Normal and Pathological Physiology of Bone its Problems By Prof R Leriche and Prof A Policard Authorised English Translation by Prof Sherwood Moore and Prof J Albert Key Pp 236 (London Henry Kimpton, 1928) 21s net

"LES problèmes de la physiologie normale et pathologique de l'os" of Leriche and Policard was published in Paris in 1926 The two American doctors to whom we are indebted for this translation plead difficulty in excuse of defects which are indeed evident There are, however, few obscurities which cannot be resolved without access to the original The French title is to be preferred to the English, because it modestly emphasises the 'problems' instead of the physiology The work is, happily, not physiological It is incorruptibly biological, and in this its remarkable character lies Areas in process of ossification are in reality regions with a sluggish circulation, with difficult interchange The composition of the blood in the great vessels permits no deduction concerning the chemical behaviour in these areas That is the weak point of all chemical research up to the present time The methods are most exact, but that is not true of the object subjected to research The problem on the whole is badly put And when well put, the methods are no longer applicable" Bone formation is a succession of phenomena hæmorrhage, de differentiation' of connective tissue, œdema, resorption of bone and its deposition in the ossifiable medium present Each of these phenomena is in itself commonplace What is peculiar is their juxtaposition The essence of the process lies in a vascular congestion acting simultaneously on the connective tissue and a calcified tissue" It is an organic result The work should be in the hands of every English surgeon, both on account of its extensive practical wisdom, and as an instruction in methods of research It is a little distressing to see the word evolution so carelessly used The original conveys a variety of meanings

The Economics of Rail Transport in Great Britain By C E R Sherrington Vol 1 *History and Development* Pp xii + 283 Vol 2 *Rates and Service* Pp xii + 332 (London Edward Arnold and Co 1928) 12s 6d net each vol

MR SHERRINGTON'S two volumes are complementary to each other, each containing the same foreword by Sir Guy Granet and the same preface, while the first volume after a short chapter on the function of transportation, deals with the growth of British railways, their rolling stock, locomotives tracks, and the regulations which are part of their history the second volume treats of the organisation and administration of railways, and their relation with the State the public, and industry His wide experience as a lecturer on economics and as secretary to the Railway Research Service enables him to write in an impartial yet authoritative manner, and no one interested in railways could fail to appreciate his masterly review The history of the British railways treats of them in the four groups as we see them to day, the review of the locomotive development is more general As to railway administration, the trend is towards a closer study of the internal economy of railway management, and from the second volume the layman can obtain some impression of the complicated nature of the problems involved

Regarding nationalisation, Mr Sherrington remarks that "it is hard to visualise in the case of the railways any very great advantage in the change over under present conditions, and it certainly would tend to decrease any desire to improve efficiency", while in his discussion on

road transport he says, 'where ruthless competition for traffic not sufficient to warrant the two systems is taking place, its development should be opposed provided the rail method satisfies public wants, and can be operated more cheaply"

Matriculation Botany a New School Course By Mary A Johnstone Pp xii + 324 (London and Toronto J M Dent and Sons, Ltd, New York E P Dutton and Co, 1928) 4s 6d

IN spite of the number of school text books of botany already available which cater for the needs of candidates of matriculation standard, teachers of such pupils would be well advised to consider Miss Johnstone's manual The author thinks that "to a large extent general knowledge of plant life is best acquired through the detailed study of the life histories of a few specially selected plants", ecology being treated as an integral part of plant study from the beginning Carrying out this idea, she uses the life histories of bluebell, lesser celandine, coltsfoot, and wheat as starting points for a thoroughly sound school course on the physiology, structure, classification, and adaptation to environment of common plants The section on soils and the notes on common trees are also worthy of special mention

The skilled teacher is in evidence throughout the book, and the scientific spirit is displayed in such comments as the following "Because these are advantages they must not be assumed to be the reasons" (why certain trees are deciduous)—an example of the kind of warning of which students of botany are in constant and peculiar need The 120 illustrations are excellent examples of the line drawings which pupils should be required to make—except in one respect the scale of magnification or reduction is consistently not stated It is, indeed, conceivable that unwary young readers might suppose, from an examination of the drawings of soil bacteria, that *Nitrosomonas* is not only of the general shape, but also of the size, of a tadpole! Another small fault, which should be rectified in the reprints which are sure to be called for, is the repeated reference to 'centimetres' of water on p 259

Dynamics a Text book for the use of the Higher Divisions in Schools and for First Year Students at the Universities By A S Ramsey Pp xii + 259 (Cambridge At the University Press, 1929) 10s 6d net

THIS book is intended primarily for students in the higher divisions of schools who intend to take an honours course of mathematics at a university, and also for university students preparing for a first honours examination The text is based upon courses of lectures given to first year students preparing for the Mathematical Tripos, and it is assumed that readers are already familiar with elementary dynamics, and have an intimate knowledge of the elements of the calculus

The subject is presented with logical precision, and in a manner which is admirably appropriate to the requirements of those students for whom the book is intended An excellent feature is the wide range of worked examples given in each chapter, and to these are added extensive series of exercises taken either from scholarship papers or from Tripos papers The contents of the chapters include kinematics, kinetics, dynamical problems in two dimensions, harmonic motion, motion under constraint, the law of reaction, impulsive motion, orbits, moments of inertia, energy and momentum, equations of motion miscellaneous problems, and small oscillations

Vorlesungen über Elektrizität Von Prof A Eichenwald Pp viii + 664 (Berlin Julius Springer, 1928) 36 gold marks

PROF EICHENWALD'S book has been carefully written and carefully printed, the list of corrections contains only one small item The text extends to 659 pages and contains 640 diagrams In Great Britain it would probably have been published in two or three volumes It is divided into three parts The first part includes the main principles on which the sciences of electricity and magnetism are founded The treatment is on the best academic lines, only the main mathematical theorems being given The second part discusses electrons both in liquids and gases, radioactivity, and electric and magnetic phenomena connected with electrons In the third part the theory of alternating currents is given, special stress being laid on oscillations and waves The practical theory of radio communication is also discussed In the final chapter the theory of Röntgen rays is given, and also the quantum theory Maxwell's theory is given fairly fully, and some of the theorems of relativity We notice that the gauss is used for the unit of magnetic force and the maxwell for the unit of magnetic flux With the notable exception of *J* instead of *I* for current, international symbols are used

The Preparation of Plantation Rubber By Sidney Morgan With a Preface and a Chapter on Vulcanisation by Dr Henry P Stevens Second edition Pp xvi + 357 (London Constable and Co, Ltd, 1928) 21s net

INFORMATION gathered at first hand is here given concerning the production and treatment of rubber, the main theme being its preparation for the market Mr Morgan, who has drawn fully upon his extensive researches on such processes as tapping, coagulation, rolling, drying, and smoking, deals with operations in the field and factory, and contributes other sections on machinery and buildings, finished rubber, and general matters, while Dr Stevens supplies the preface and an outline of the important subject of vulcanisation Among new matter included in the second edition, attention is directed in particular to bud grafting, cover plants, and manures The book is well produced, generously illustrated, and full of valuable practical information which cannot fail to be of service to all who are concerned with the growing, curing, packing, manufacture, or general handling of rubber and rubber goods

Diffraction of Electrons by a Copper Crystal

INVESTIGATIONS of the secondary electron characteristics of a poly crystalline copper surface have shown that maxima and minima appear in the low voltage region of the total secondary electron curve only after the copper target has been heated at rather critical temperatures (*Phys. Rev.*, 25, 41, 1925). Accompanying the appearance of these maxima and minima, a change has been observed in the angular distribution of the secondary electrons (*Phys. Rev.*, 31, 414, 1928). These considerations, together with others (*Phys. Rev.*, 31, 419, 1928), make it appear that the changes in slope in the low voltage region of the characteristic secondary electron curve of a metal are a function of the orientation of the surface crystals, as are also the directions of the scattered electrons.

It thus appeared advisable to measure the total secondary emission from a single copper crystal under the same conditions as the angular distribution of scattered electrons. This has been done for bombarding potentials between 1 and 150 volts.

The apparatus is constructed of molybdenum to eliminate magnetic effects and the earth's field is compensated by Helmholtz coils. A special type of electron gun is used which produces a more intense beam of electrons than the usual type for the very low voltages (*J.O.S.A. and R.S.I.*, 15, 290, 1927). The electrons strike at normal incidence the (100) face of the copper crystal which is placed at the centre of a drum. One edge of the drum is made with a slot so that electrons may pass through and into the opening of the double Faraday box, which may be rotated from the plane of the target to within 13° of the incident beam. The target may also be rotated about an axis perpendicular to its face and may be removed into a side tube where it may be heated to red heat by bombardment. The moving parts are operated by magnetic controls which are sufficiently far removed to cause no measurable effect at the target. In taking observations on angular distribution the potential of the inside Faraday box is so adjusted that electrons which have lost more than 1 volt at the target are not permitted to enter.

The total secondary electron curve shows two maxima in the low voltage region at 3 volts and 10.5 volts respectively. Several marked changes in slope occur in the region between 10.5 volts and 150 volts. Intense electron beams are found to issue from the crystal at potentials for which the above maxima occur and at such potentials as to account for many of the changes in slope between 10.5 and 150 volts. Others may be accounted for by the diffraction beams which would be expected to leave the crystal in the direction of the normal but are outside of the solid angle of observation. It thus appears that the energy levels of the atom at most play only a comparatively small part in the production of sudden changes in slope in this region, since the electron diffraction beams apparently depend only on the positions of the atoms and not on their structure.

Now, a consideration of the wave length of the electron and the atomic spacing of a copper crystal shows that no electron beams due to diffraction are to be expected in the very low voltage region in the solid angle accessible to observation, since the plane grating formula $n\lambda = d \sin\theta$ must be satisfied, and the maximum possible wave length is obtained for $\sin\theta = 1$. Hence most of the beams in the low voltage region have no X-ray analogues. They do occupy, however, the approximate positions to be expected by a wave of one half the length given by the usual expression $\lambda = h/mv$, if a value greater than unity is taken for the refractive index.

Seven sets of electron beams are found to issue from the crystal in the two principal azimuths which are the X-ray analogues and require a refractive index greater than unity. In addition, 8 sets of beams are found in the (100) azimuth which may be accounted for by assuming a wave length for the electron which is one half that given by the formula $\lambda = h/mv$. One other weak set in this azimuth is unaccounted for by either of the above relations. In the (111) azimuth 3 sets are accounted for by the one half λ relation. There are 4 other sets in this azimuth, 3 of which may possibly be accounted for by a one third λ relation, while one weak set appears anomalous. In addition to the above the 3 volt beams do not appear accurately in either azimuth and are not reproducible.

Many of the beams are remarkably strong and sharp. In the case of a 70 volt beam the background scattering in azimuth is found under the best vacuum conditions to be only 4.3 per cent of the maximum intensity of the beam.

The sets of electron beams accounted for by the above relations, with one exception, require a refractive index greater than unity. However, the voltage differences between the electron beams and their X-ray analogues are found in general to increase with the voltage from about 6 or 7 volts for the lowest, to about 30 volts for the highest voltage in the range below 150 volts. The exceptional set, which is very weak, requires a refractive index of about unity with the association chosen.

The electron beams satisfying the $\lambda/2$ relation would also be accounted for by whole λ wave lengths and twice the atomic spacing for a copper crystal and might thus suggest a surface gas grating having twice the copper spacing. Such plane grating beams have been observed by Davisson and Germer (*Phys. Rev.*, 30, 705, 1927) from the (111) face of a nickel crystal. The beams observed from the copper crystal, however, appear not to be due to gas, for they are space grating beams and not surface grating beams. Further, they are observed under the best vacuum conditions, which must be of the order of 10^{-8} mm. mercury, and only a few minutes after the crystal has been heated at red heat, that is, while it is still considerably above room temperature. A temperature effect of these beams has been observed similar to that of the whole λ beams. The beams attain their maximum intensity about one half hour after heating. The copper crystal has been heated at red heat for several hours so that no pressure is observable on a sensitive McLeod gauge (a distance of 0.75 mm. in the top of the gauge capillary corresponds to 10^{-6} mm. mercury), while the crystal is at red heat.

If the possibility of an effect due to gas is ruled out, it appears necessary to conclude either that there are wave lengths associated with the electron in addition to that given by the formula $\lambda = h/mv$, or that the electron waves are scattered from alternate rows of the copper atoms with different intensities, both in the plane grating and the space grating. Because of the 4-fold symmetry in azimuth, the crystal appears to be single. Since the crystal was formed by the method of melting and slow cooling in an atmosphere

of hydrogen, the possibility of contamination by copper oxide should be eliminated The experiments will be continued with other crystals

Some further Observations on *Amoeba proteus*

DR MURIEL ROBERTSON'S paper entitled 'Notes on certain points in the Cytology of *Trypanosoma raiae* and *Bodo caudatus* ' (*Paras* vol 19, No 4, Dec 1927) made me resolve to re investigate the nucleus of *A proteus* in the various stages of its life history by means of Feulgen's Reaction A full account of this chemical test for chromatin, as well as a Table of Procedure drawn up from her own experience, is given by Dr Robertson I had to modify this table in some respects *A proteus* is too heavy to remain adherent to the slide during all the drastic procedure involved in bringing about the reaction I therefore made use of the method used on previous occasions that is, of carrying on all the operations in a centrifuge As it was not practicable to wash the amoebæ in running water the liquid in the centrifuge tube was replaced by water and this was changed five times, at 15 minute intervals

Dr Robertson placed no ban on acid containing fixatives I therefore began my experiments by using Bouin's modified formula (Duboscq Brasil 1905) The formalin in it helped to harden the cytoplasm It was found necessary in the case of *A proteus* to treble the time allowed by Dr Robertson That this need was due to the nature of the *A proteus* nucleus rather than to the modifications in method described above, was proved by control experiments in which flagellates and ciliates were found to be brightly coloured after normal exposure to the stain

The interesting new fact that emerges from this study is that the *whole* of the karyosome of the *A proteus* nucleus gives the reaction for chromatin just as positively as does the macro nucleus of a ciliate Amid the general substance of the karyosome irregular patches are more deeply stained and the chromatin 'blocks' in the periphery are also a deep red The achromatic structures show up in marked contrast, especially when light green is used as a counterstain None of the cytoplasmic structures are affected by the Feulgen with or without hydrolysis

Consequent on the failure to obtain positive results for the karyosome of the nucleus of young immature *A proteus* even after prolonged staining non acid corrosive alcohol and absolute alcohol were tried as fixatives, lest the failure should be due to the Bouin's fluid previously used The results were the same the karyosome again failed to give the reaction The 'blocks', which are extremely small were faintly red, and there was a diffuse red stain surrounding the blocks in the periphery The nucleus of the young *A proteus* would appear to contain very little chromatin, a conclusion borne out by its great affinity for plasma stains

The colour produced by fuchsin after fixation in a non acid fixative is much more pink and less purple

This study has necessitated a renewed and detailed scrutiny of many cultures of *A proteus*, and in view of the fact that a flagellate stage, followed by syngamy, has recently been described as occurring in the life cycle of *A proteus*, I should like to record, once more, that in spite of years of study I have failed to find any such stages The life cycle, in fact, would appear to be wholly asexual

Amoeba bigemma **bears a superficial resemblance to young stages of *A proteus* It can easily be cultivated** under the same conditions as *A proteus* *Amoeba verrucosa* similarly grows readily under these same conditions, and when it is young is extremely active in movement Stained preparations of each of these could easily be mistaken for young *A proteus* from their nuclear characters, unless the cytoplasmic characters of each had been observed before fixation of the specimen So far as I am aware, the life cycle of neither of these species has been worked out, and therefore the existence in them of a flagellate stage is not excluded, although in my opinion unlikely

Cultures of *A proteus* are liable to be attacked and even killed off by a flagellate parasite and it is conceivable that this has been interpreted as a phase in the normal life cycle of the amoeba

It is of interest to note that in 1918–19 a strain of *A proteus* was observed to contain symbiotic green flagellates The culture was unfortunately exhausted for supplying class and demonstration material I have never had time to investigate the matter nor to make any experiments in bringing about the conditions which induced the symbiosis The symbiont has a nucleus typically flagellate, of about 60 μ and its own diameter in stained preparations is from 150 μ to 180 μ Some of these preparations contain four symbionts in a single amoeba

Although *Euglena nematoides* is a frequent inhabitant of *A proteus* cultures the amoeba do not seem to be able to prey upon it as they do on other flagellates at least in its active stage Although I have often watched a conflict between the two I have always found that the *Euglena* makes its escape

Negrito Racial Strain in India

IN a short note in NATURE of May 19, 1928 (vol 121, p 793) I mentioned the discovery of a truly negrito strain among the Kadars in the extreme interior of the Cochin Hills (S India) As a result of further investigations in the adjoining hills made this year I was able to find 10 more individuals showing spirally curved hair making a total of 16 (a little more than 10 per cent) out of 157 men and women measured Of the 10 individuals found this year, 8 were Kadars, and the remaining two were a Pulayan and a Malser The hair of all of those except two, who have very short spirals (Fig 1*a*), are of frizzly type similar to that of the Melanesians (Fig 1*b*), matching No '*q*' in Martin's scheme ('Lehrbuch ", 2nd edition, vol 1, p 213) The hair of the two with short spirals would resemble '*h*' rather than '*i*' in the same scheme In appearance they are without exception very dark, the skin colour varying from 29 to 34 in Von Luschan's scale, short, prognathic, having thick everted lips, short broad nose flattened at the root with the tip tilted up The average cephalic and nasal indices of the 10 are 75 23 and 85 6 respectively, bringing them just within mesocephaly and platyrhiny

The presence of the Melanesian form of hair is interesting, because it definitely links up the aboriginal people of S India with Melanesia , but of the short woolly haired type I am not so certain I am inclined to regard it as distinct from the frizzly haired type unless the latter may be considered the result of hybridisation with the wavy to curly haired type which forms the dominant element among the Kadars at present Whatever may be the ultimate explanation of this, there is no doubt that among the aborigines of S. India there still persists in the extreme interiors a primitive element of a genuine negrito

character, as shown by its occurrence not merely among the Kadars but also among the Pulayans and the Malsers It is not impossible that such a type exists among other aboriginal tribes of Southern and Central India in regions which have not so far been carefully explored Dr J H Hutton's discovery ("Man in

a *b*

FIG 1 —Kadars of the Cochin Hills with woolly and frizzly hair respectively

India", vol 7, No 4, pp 257 262) of spirally curved hair among a section of the Angami Nagas would extend it to the eastern frontiers and lend support to the view of the wide distribution of the negrito type at one time in India

The results of my investigations on the Kadars of the Cochin and Anamalai Hills will be published as soon as the details are worked out

Penetrating Radiation and de Broglie Waves

BOTHE and Kolhorster have recently published a preliminary account of an experiment on the absorption coefficient of the penetrating radiation (NATURE April 27, p 638) They conclude that this radiation is of corpuscular rather than of gamma type The purpose of this note is to show that their experiment may be inconclusive

The de Broglie wave length (de Broglie, "Ondes et Mouvements" 1926, p 10) for an electron moving with velocity v is

$$\lambda_B = \frac{h\sqrt{1-\beta^2}}{m_0 v}$$

If this electron were suddenly stopped, the wave length of the emitted quantum would be, on the basis of Einstein's photoelectric equation

$$\lambda_E = \frac{h}{m_0 c}\,\frac{\sqrt{1-\beta^2}}{1-\sqrt{1-\beta^2}}$$

The ratio
$$\frac{\lambda_E}{\lambda_B} = \frac{\beta}{1-\sqrt{1-\beta^2}}$$

approaches unity for wave lengths of the order of magnitude of those under discussion For example Millikan and Cameron (*Phys Rev* [2], **31**, 921, 1928) give 0 00008 A for the wave length of their most penetrating radiation If one takes $\beta = 0\ 99999$, then $\lambda_E = 0\ 000109$ A and $\lambda_E/\lambda_B = 1\ 0045$

The results of experiments (Davisson and Germer *Phys Rev* [2], **30**, 705, 1927, Kikuchi *Proc Imp Acad Tokyo*, **4**, 471, 1928) have shown that the de Broglie wave length of low velocity electrons can be used to explain their reflection from and diffraction in crystals It is suggested by analogy that, in the scattering of high velocity electrons and high frequency electromagnetic radiations of the same energy, the distribution in angle and the energy relations between the incident and scattered rays may be nearly identical

If one assumes the mass of an electron and the mass of a quantum to be respectively

$$m_e = \frac{m_0}{\sqrt{1-\beta^2}} \qquad m_q = \frac{h\nu}{c^2},$$

and uses the above expression for λ_E, it is seen that

$$\frac{m_e}{m_q} = \frac{1}{1-\sqrt{1-\beta^2}}$$

For the velocity considered above $\frac{m_e}{m_q} = 1\ 0045$

From this one may derive further grounds for extending by analogy, the already established duality to the present case In the scattering formula of Klein and Nishina (*Zeits f Physik* **52**, 853 1929), ν occurs only in the factor $h\nu/m_0c^2$ Therefore if one substitute m for $h\nu/c^2$ the numerical result is changed only slightly for large values of β

If the above hypothesis should be valid, the analysis of penetrating radiations at the surface of the earth into electrons or light quanta might be impossible by means of simple scattering or absorption experiments

It is also possible that some of the rays from radioactive substances recently classified as short wave gamma rays may in reality be high speed beta rays

Magnetic Properties of Isolated Atoms of Cobalt

FERRO MAGNETISM is one of the most complicated and least explained subjects This is because in most of the experimental work what are observed are statistical phenomena from which it is difficult to arrive at a knowledge of the elementary mechanism It was therefore thought interesting to investigate alloys of a small percentage of cobalt with platinum namely, 10 per cent Co – 90 per cent Pt and 5 per cent Co – 95 per cent Pt in which the ferro magnetic cobalt atoms are not generally surrounded by other magnetic atoms but by non ferro magnetic platinum atoms

These alloys were found ferro magnetic, the Curie point being 249° C and 49 C for the 10 per cent and 5 per cent alloys respectively The magnetisation, I, at different temperatures from that of liquid air up to the Curie point was found for each alloy, the decrease in magnetisation near the Curie point being most rapid for the 5 per cent alloy For small values of the applied magnetic force (H – 0 to 100 gauss) I increased at first with temperature, but for greater values of H it decreased steadily The greatest values of I obtained ($H = 565$ gauss) were 364 and 254 C G S units for the 10 per cent and 5 per cent alloys respectively This corresponds to a magnetic moment per cobalt atom 25 per cent and 60 per cent greater than that calculated from the saturation magnetisation of pure cobalt, assuming the platinum atoms do not contribute to the magnetisation

Finally, various hysteresis loops showing the relation between I and H were obtained These were found to vary considerably with the heat treatment For wires in the hard drawn state, the 5 per cent alloy gave the larger and more rectangular loops, with a coercive force as great as 100 gauss but after annealing at different temperatures, the hysteresis was greatly reduced, the 5 per cent alloy showing a coercive force of only 20 gauss as against 28 for the 10 per cent alloy This last result, for the annealed wires, is in accord with Heisenberg's theory of ferro magnetism based on the resonance between the

spinning electrons of neighbouring atoms (*Zeit f Phys*, **49**, 619, 1928), on this theory one would expect less hysteresis as the magnetic atoms become more isolated The theory also explains the effect of annealing in reducing the hysteresis by uniformly distributing cobalt atoms which were closely clustered in groups in the hard drawn state, and thus likewise reducing resonance phenomena

The Atomic Weight of Arsenic

As the International Committee on Atomic Weights has not provided a table since 1921, the British Sub Committee published in the *Journal of the Chemical Society* of January last a revised table of atomic weights for 1929 In the report attached to this table we read that "for the nine 'simple' elements H, He, C, N, F, Na, P, As, and I the values obtained by F W Aston with his new mass spectrograph are adopted in preference to those deduced from the physical or chemical data, because we are of opinion that, in these cases, Aston's method is less liable to error than any other"

Dr Aston is to be congratulated that his spectro graph allows the reading corresponding, as regards the accuracy, to that of modern atomic weights deter mination, namely, 1 in 10,000

Since from the year 1927 I have been engaged on the revision of atomic weight of arsenic, based on chemical analysis, I am highly interested in the new Aston figure, As = 74 934, derived for this element from the mass spectrum alone The atomic weight of arsenic, As = 74 96, hitherto adopted internationally, is based on the Baxter and Coffin method of converting silver arsenate into silver chloride or silver bromide by the action of hydrogen chloride or hydrogen bromide From the chemical point of view this international value for arsenic is a little higher than the actual one From this reason I have undertaken a new determination of this figure deduced from the analysis of the purest arsenic chloride and bromide From the eight determinations of the ratio $AsCl_3$ 3Ag hitherto made, I have obtained the average As = 74 937 (using Ag = 107 88 and Cl = 35 458), which is in ex cellent agreement with the value obtained by Aston This agreement corroborates the probability of the lower value, which was to be expected, and shows at the same time the trustworthiness of Aston's method used for the derivation of atomic weights of simple elements

My preliminary paper concerning this matter was read before the Congress of Czechoslovak Scientists held in Prague, May 1928 After completion of the analyses of arsenic chloride and those of arsenic bromide, the definite value obtained will be published

A New Ultra-violet Band Spectrum of Hydrogen Chloride

HITHERTO no band spectra have been found which involve electronic excitation in neutral or ionised hydrogen chloride We have recently photographed an extended band system in the region λ2830 λ3966 from a low pressure discharge in pure hydrogen chloride gas with platinum electrodes The bands are degraded toward long wave lengths, and have the characteristic widely spaced structure always observed in hydride spectra A discharge in hydrogen gives the same band system if a small amount of silver chloride or cuprous chloride is fused on the electrodes, but not if silver bromide is used Thus there is strong evidence that this spectrum is due to the hydrogen chloride molecule Moreover, there are reasons, both experimental and theoretical, for believing that the emitter is singly charged, probably the HCl^+ ion For example, the bands are obtained only from the negative glow, whereas in general the spectra of ionised molecules, such as N^+_2, are relatively stronger

Owing to the unusual intensity distribution in this band spectrum, it has not been possible to reach an assignment of vibrational quantum numbers, and thus to determine the electronic frequency The isotope effect, which we hope to obtain by the detailed analysis of the fine structure now in progress, should prove helpful in this regard The bands occur in pairs of constant separation, 658 cm^{-1}, indicating that a doublet electronic level is involved The two components of a pair have about equal intensities The wave numbers of the band heads may be repre sented by

$$\nu = \left.\begin{matrix} 28446 \\ 27788 \end{matrix}\right\} + 1561p - 30\,3p^2 - 2573n,$$

observed values of (p, n) being $(-1, 0)$?, $(0, 1)$ $(3, 1)$?, $(0, 0)$, $(1, 0)$, $(2, 0)$, $(3, 0)$, $(4, 0)$, $(5, 0)$ The pair $(0, 0)$ at λλ3514, 3598 is the strongest, and the five succeeding pairs have regularly decreasing intensity They apparently form a progression with a common vibrational quantum number in the lower state As was pointed out to us by Dr F Hund, it can be shown by a correlation with the energy terms of the equiva lent atom, Cl, and the separate atoms H and Cl^+, that a transition $^2\Sigma \dashrightarrow {}^2\Pi$ might be expected in HCl^+ A preliminary examination of the rotational structure shows that it is probably compatible with such an interpretation

Dirac Equations and Einstein Theory

HERMANN WEYL (*Proc Nat Acad of the U S A*, **15**, 323 April 1929) has recently developed a relativ istic theory of the Dirac equation which, like that of Wigner (*Zeit f Phys*, **53**, 592, 1929), and that of Vallarta and myself (NATURE, Mar 2, 1929, p 317), employs the Einstein notion of an '*n* leg' Unlike the two other theories, Weyl rejects Einstein's dis tant parallelism, and obtains a theory invariant under a local rotation varying continuously from point to point That is, Weyl's theory depends solely on the $g_{\lambda\mu}$'s of Einstein's 1916 gravitational theory, and not on the ${}_s h^\lambda$ of his 1929 theory It is perhaps interest ing to remark that the same degree of invariance may be obtained by choosing as the 4 legs of the Einstein theory the Ricci principal directions If we write $R_{\lambda\mu}$ for the 1916 contracted curvature tensor, this addi tional condition is expressed by the formula

$${}_t h^\mu {}_s h^\lambda R_{\lambda\mu} = 0 \quad (s \neq t) \qquad (1)$$

This condition is trivial and nugatory in case the original Einstein equations $R_{\lambda\mu} = \text{const}\ g_{\lambda\mu}$ are ful filled Since the new gravitational electric matter equations, whatever their final form may be, are close approximations to these, it is perhaps not too much to hope that the supplementary condition (1) not only is compatible with them, but even not too restrictive so far as terms of observable magnitude are concerned

Thus gravitational phenomena appear to be such

as can occur even in a homogeneous Riemann space, whereas matter electrical phenomena depend on the inhomogeneity of space This may well have some thing to do with the absence of spherical symmetry in the spin inseparable from the electron

So far as the quantities ${}^{i}h$ are concerned, the new auxiliary condition is of the second order The new Einstein field equations will probably not be of the second order when written in terms of the $g_{\lambda\mu}$'s, but it is not clear that the Weyl equations will escape this criticism The supplementary condition (1) leaves untouched the work of Wigner, Vallarta and myself Thus the Dirac equations may be treated relativistic ally on the basis of the Einstein 1916 theory

Diamagnetism and Crystal Structure

PROF EHRENFEST has suggested (*Physica*, vol 5, p 388, 1925) that the high diamagnetic susceptibility of bismuth is to be ascribed to the existence in the metallic crystal lattice of electron orbits of large area including several atoms within their radius There seems good reason to extend Ehrenfest's hypothesis to the case of carbon as well, since it affords an illu minating insight into the magnetic behaviour of the different forms of this element It is known that graphite possesses a high specific susceptibility, which according to the most recent measurements of Vaidyanathan with carefully purified samples, is $-5\ 1 \times 10^{-6}$, that is, quite ten times larger than the specific susceptibility of diamond ($-0\ 49 \times 10^{-6}$), the latter being practically the same as that of carbon in organic compounds as found from Pascal's additive law The abnormal susceptibility of graphite be comes intelligible in terms of the peculiar structure of the substance and its electrical conductivity, if we assume that there are electron orbits circulating round the plane hexagonal rings of carbon in the crystal lattice This fits in with the known fact (observed by Honda and Owen) that the susceptibility of graphite is six or seven times greater normal to the planes of cleavage than parallel to them Diamond, on the other hand, being a dielectric would naturally not show the abnormal susceptibility

Careful studies made by Mr P Krishnamurthi of the X ray pattern of sugar charcoal and lamp black prove conclusively that these substances do not possess any crystalline structure The fact that amorphous carbon has the normal susceptibility ($0{\cdot}51 \times 10^{-6}$), and not the high value of graphite, is therefore quite to be expected The great diminution in the susceptibility of bismuth which occurs on fusion may be regarded as an analogous phenomenon

Ehrenfest's hypothesis would appear to have also other fruitful applications, for example, in the ex planation of the remarkable diminution in the sus ceptibility of graphite at high temperatures and of the dependence of susceptibility on particle size in colloidal substances We need not, however, enter into those details here

Salt Haze

I HAVE at intervals during the last few years directed attention to the presence of salt particles in the air and their importance in facilitating the formation of fog, since in the presence of a haze of sea salt con densation would commence upon the particles long before saturation is reached.

On May 27 last I was fortunate enough to observe a salt haze in process of generation I was on the north bank of the Tagus at about 8 A M , summer time It was a bright sunny morning, with a light wind from the north west, and looking across the river I observed a long stretch of sandy shore extending southward from the mouth of the Tagus I had a good view along this stretch of shore, and noticed that a well marked haze commenced along the line of the breakers and was carried seaward by the wind, extending gradually so that it partly obscured the hills in the distance There was a clearly defined line over the breakers where the haze commenced, and it was obviously formed from the spray On looking in the opposite direction over the land visibility was good, and practically no haze was to be seen

Later in the day, that is about 11 A M , in passing up the coast northward from the Tagus I saw another example of the same thing

In a small bight or bay of the coast there was a large number of rocks projecting from the water, and these caused a good deal of disturbance and spray due to the waves , from the surface of this bay a drift of haze was quite visible passing inland The sun was shining brightly at the time, and in this case as well as in the first mentioned, the haze was white In the latter case, doubtless the fine salt particles were carried inland to a considerable distance It is possible that few of them survive the cool, still night, when the air becomes cooled and condensation on the particles must tend to bring them down

Rise and Fall of the Tides

IN NATURE of April 27, Mr A Mallock writes on rise and fall of the tides, and illustrates his views by three specific cases in which a constant amount of energy is continually concentrated into a diminishing mass To quote briefly A heavy flexible cord passes through a hole in a fixed horizontal plate The part below the plate is given an initial oscillation and swings as a pendulum The cord is then drawn upward through the hole The part above the plate is stationary, and the energy it contained is trans ferred to the part still hanging free, the mass of which continually decreases Hence the velocity of oscilla tion tends to become infinite when the length vanishes

Surely in this case it has been overlooked that as the cord is pulled up work is being done against the centrifugal acceleration, so that the kinetic energy of the moving portion is not constant, but is con tinually increasing ?

The case is analogous to that of a conical pendulum formed by a bob at the end of a string , if the string be shortened by any means the kinetic energy of the system is increased The same principle occurs in two common forms of human activity , the child swinging rhythmically raises his centre of gravity while his angular velocity is great and lowers it while it is small , the skater, moving over the ice by what is known as the Dutch roll, progresses by a series of alternating curves, never lifting his skates from the ice He rhythmically raises his centre of gravity while going round the curve (*i e* shortens the conical pendulum), and lowers it while reversing the curvature of his path By this means he steadily puts energy into the moving system, without its being obvious to the non skater how he is doing it

The Late Palæozoic Glaciation

By Dr H DIGHTON THOMAS

THE great continent of Gondwanaland existed in the late Palæozoic in the southern hemisphere and persisted through a long period of geological time with little modification The deposits formed on it are found in Australia, India, South Africa, South America, and Antarctica, where beds of glacial origin generally occur at the base of the series The fossilised remains of the flora which flourished on the continent in its early stages are found sometimes in, and generally above, the glacial horizon Characteristic plants are species of *Gangamopteris* and *Glossopteris* The whole floral assemblage is very different from that yielded by the Upper Carboniferous and Permian continental deposits of the northern hemisphere, in which the Pteridosperms (*e g Alethopteris*), Lycopodiales (*e g Lepidodendron*), Equisetales (*e g Calamites*), and Cordaitales (*e g Cordaites*) predominate

Intimately linked with the problems of Gondwanaland are the questions of the age of the late Palæozoic glaciation and of the age and range of the *Glossopteris* flora Was the glaciation in Carboniferous [1] or in Permian time? Did the first members of that flora exist contemporaneously with the latest Carboniferous flora of the northern hemisphere, or did they make their appearance later, in the Permian? For long, different opinions have been held, though in general those of British geologists have tended more and more definitely towards a belief in a Uralian age (Upper Carboniferous), both for the glacial period and for the entry of the *Glossopteris* flora Prof C Schuchert has recently attempted to answer the question decisively (*Bull Geol Soc America*, vol 39, No 3, 1928, pp 769 886), and in doing so has performed an invaluable service in bringing together in an accessible and summarised form a mass of stratigraphical and palæontological details In his long paper Schuchert deals with the evidence furnished by most of the important localities in the southern hemisphere and in India To these he adds résumés of the important Russian, German, and North American horizons which bear on the problem to be solved His conclusions briefly are that the glaciation occurred "in Middle and probably in Late Middle Permian time", and that the *Glossopteris* flora does not range back beyond that period In these conclusions Schuchert states that he has the support of Dr David White, the noted American palæobotanist

Fundamentally, in making his correlations Schuchert uses as a standard the succession in the Salt Range, so that the determination of the age of the latter is of prime importance The whole of the Productus Limestone and of the underlying beds down to the Talchir Boulder Bed he assigns to the Permian, firstly, on the evidence of Upper Permian ammonites (*Xenaspis* and *Cyclolobus*) in the Virgal and Chideru groups, and secondly, because of "how intimately the whole of the Productus Limestone is tied together faunally" The latter statement rather overstates the case The number of species, particularly of the Brachiopoda, that range through the Productus Limestone Series is small, and it is highly dangerous to use such long ranged forms in correlation The ammonites give the age for the containing beds, but are no proof of the age of those below them They first occur in the Salt Range in the zone of *Xenaspis carbonaria*, the whole of the succession of about 800 feet below that horizon down to the glacial bed being devoid of such forms The age of these beds can be deduced only from a consideration of their faunas, and particularly from the Brachiopoda, because of the knowledge we possess of their range in time

From this point of view the first important fossiliferous horizon above the Talchir Boulder Bed is the Amb group of Noetling, approximately equal to the Lower Productus Limestone of Waagen, this Schuchert refers to the Basal Upper Permian The faunal evidence will scarcely support this opinion From this horizon Waagen described a large fauna which has to some extent been emended by Noetling and Koken The faunal lists given by the latter, and by Waagen, show a large number of forms which occur also in the Urals and in Timan In that classic and standard area for the Upper Carboniferous most of the forms common to the Russian area and to the Amb Series do not range above the Artinskian (Lower Permian), and the majority of them not above the *Schwagerina* zone (Upper Carboniferous) As examples, *Dielasma itaitubense*, *Hemiptychina sublævis*, *Derbya regularis*, *D grandis*, *Rhipidomella pecosi*, and *Spirifer ravanah* may be cited Schuchert himself draws attention to the fact that "The Amb stage is characterised below by *Spirifer marcoui*", a species which he is careful to state does not range higher than the *Cora* zone (Uralian) in the Urals Even without considering the absence of such forms as the curious Brachiopod *Lyttonia* from the Amb fauna (which may not be an essential point in the argument) it becomes impossible to maintain for the Amb stage an age younger than Lower Permian At the latest a low horizon in the Artinskian is indicated Such being the case the underlying Speckled Sandstone, including the *Eurydesma* and *Conularia* zones—important for the correlation of the Australian and South African successions—and the Talchir Boulder Bed are of high Carboniferous (Uralian) age

Some confirmation is given by the recently described fauna from the Umaria coalfield of Central India Above a slight unconformity on the Talchir Boulder Bed occur thin marine, fossiliferous bands which are stated to pass up into the Barakar Series of continental origin The fauna is not a rich one, but its importance from its position above the

[1] The boundary between the Carboniferous and the Permian is here taken at the top of the *Schwagerina* zone and not, as drawn by Schuchert, at its base.

glacial horizon is obvious Cowper Reed placed its age as Permo Carboniferous and directed attention to its affinities with an Upper Carboniferous fauna It is doubtful if he implied by the use of the term 'Permo-Carboniferous' a definite Lower Permian age as Schuchert takes it to mean, it is more probable that he meant that the fauna might be either Upper Carboniferous or Permian in age, but that it is difficult to determine which from the evidence Even accepting a Lower Permian age for the fauna, it is difficult to see why Schuchert should reject such a determination, and state that the Talchir stage is Middle Permian, largely because the Barakar stage is stated to be Middle Permian The marine evidence is far more trustworthy than a correlation made through the fact that the beds pass up into the Barakar Series Ultimately the latter has to be correlated with marine successions, since our standards are founded on them From the evidence of the marine beds in the Umaria coal field a Carboniferous age for the Talchir stage is not improbable In the Indian Peninsula the latter stage, as well as the succeeding Karharbari stage, yields *Gangamopteris* and *Glossopteris*, so that there is strong indication that the establishment of the *Glossopteris* flora occurred at least in Lower Permian time, if not actually in the Carboniferous The occurrence of *Gangamopteris* in Kashmir in no way invalidates this The beds yielding them lie below the Permian Zewan beds, but the plant bearing horizons occur at a distance of 400 feet at least below the base of the Zewan series

The *Eurydesma* and *Conularia* faunas of the Salt Range are repeated in New South Wales and in South-West Africa, in both cases above glacial beds If these faunas are reliable guides they indicate an Upper Carboniferous age for the Lower Marine Series of the Hunter River in New South Wales, and for the Upper Dwyka Shales of South-West Africa Such an age has been accepted by Dr Du Toit and Prof Gregory among others The latter has directed attention elsewhere to the Carboniferous, as opposed to the Permian, aspect of the fauna of the Lower Marine Series of the Hunter River succession Thus not only are the glacial beds at the base of that series proved to be of Upper Carboniferous age (an opinion shared with Prof Sir T W Edgeworth David), but also the *Glossopteris* flora to have appeared in the Australian area at a similar time—leaves of *Gangamopteris* occur in places in some of the beds which comprise the Lower Marine Series An easy correlation can be effected between the Seaham Harbour Glacial Beds of New South Wales and the Bacchus Marsh Beds of Victoria, the Glacial Boulder Beds of Tasmania, etc The Greta Coal Measures, with abundant *Gangamopteris*, most probably represent the top of the Carboniferous development in New South Wales, the Upper Marine Series still faunally close to the Carboniferous probably marking the beginning of the Permian

On the Irwin River in Western Australia glacial beds are known to occur below marine horizons which are themselves overlain by Coal Measures If these latter are correctly correlated with the Greta Coal Measures of Eastern Australia, then the glacial beds which occur far below them in the sequence are also of Upper Carboniferous age Of the fauna of the marine beds in the Irwin River area the most important member, in some ways, is *Paralegoceras jacksoni*, the only Cephalopod so far recorded from there Its affinities (and by the kindness of Sir Edgeworth David the writer has had the opportunity to examine several specimens) are with Upper Carboniferous forms, and as far as one may rely on this species it supports an Upper Carboniferous age for the bed which yields it in large numbers and for the glacial beds below The rest of the fauna shows some anomalies, as Sir Edgeworth David has indicated It is unfortunate that Schuchert does not consider this glacial occurrence

Before leaving the question of the Australian beds, attention might be directed to the alleged presence of the ammonoid, *Agathiceras*, in New South Wales and in W Australia As importance is often attached to this in making correlations (and Schuchert himself mentions the occurrence), it is not beyond the point to state that some time ago Dr Spath and I examined the specimens in the British Museum (Natural History) sent over as that species They could all equally well be Bellerophontids A few months ago I received a letter from Dr F W Whitehouse, of Queensland University, stating that he had published a note in Australia some three years or so ago to the effect that the so called *Agathiceras micromphalum* is a Bellerophontid

Reference has already been made to some evidence for an Upper Carboniferous age for the Dwyka Conglomerate of South Africa The occurrence of the fish *Palæoniscus*, and of the crustacea *Anthrapalæmon* and *Pygocephalus*, in the Upper Dwyka Shales does not invalidate this, as Dr Du Toit has pointed out Dr A W Rogers has expressed a similar view Of great interest is the discovery of remains of the *Glossopteris* flora *beneath* the tillite at Strydenburg and at Vereeniging Prof Seward and Mr T N Leslie described the flora from the latter place—the *Glossopteris* and *Gangamopteris* leaves were associated with genera common in beds in the northern hemisphere, *Lepidodendron*, *Cordaites*, *Sigillaria*, and *Psygmophyllum* These hardly demonstrate an horizon as high as Middle Permian, to which Schuchert assigns the Dwyka Tillite The flora and the invertebrates together indicate an Upper Carboniferous age not only for the glaciation but also for the first members of the *Glossopteris* flora, an interpretation accepted by Prof Seward Du Toit has well said of another occurrence, "It might be remarked at the outset that the majority of the members of the *Glossopteris* flora are of *little or no value* in establishing the *absolute age* of the beds Recent work has been showing more and more that certain genera and species thereof had a long range in time " The Ecca beds (2000-6000 ft thick), which succeed the Dwyka Series, are, in Schuchert's view, of *Basal* Upper Permian age It is an amazing, though not necessarily incredible, development for such a small period of time

By means of the Upper Dwyka Shales, and more particularly from the "White Band", which yields the marine reptile *Mesosaurus tenuidens*, we can date the glacial deposits of South America It is generally admitted that that band and the Iraty Black Shales of the Paraná Basin are contemporaneous, so that, granted that the "White Band" is Upper Carboniferous in age, the Iraty Black Shales, which yield species of *Mesosaurus*, are also of that age But beneath them occur the Rio Bonito Coal Measures, with a typical lower Gondwana flora, including *Gangamopteris obovata* and *Glossopteris* spp, while lower down still are the Itarare Beds with a basal glacial horizon Du Toit has also adduced evidence for a Carboniferous age for the glaciations in the San Juan area of Argentina, in which region he believes that the *Glossopteris* flora, if not actually occurring with elements of the Northern Carboniferous flora, occurs in beds which are only slightly later than those yielding *Cardiopteris*, *Rhacopteris*, etc This glaciation and that of Barreal, where a glacial tillite is overlain by beds with a marine fauna shown by Cowper Reed to be of early Uralian age, receive scant reference by Schuchert

Prof Schuchert has performed an arduous task in compiling his lengthy work, and he deserves the thanks of all those who are interested in the problem with which he attempts to grapple We may differ from him, and contend that the evidence he adduces is more in accord with a Uralian age for the late Palæozoic glaciation and for the first appearance of the members of the *Glossopteris* flora But at least his arguments will stimulate renewed interest and thought on one of the big problems of the stratigrapher and of the palæobotanist

The Hormones of the Sexual Glands[1]

THE influence of the ovaries on other tissues is an established fact, less is known of the effect of other glands upon the ovaries, but evidence is accumulating that the maturity and periodicity of function of the female sexual glands depend on influences from other tissues or glands of the body Grafting experiments have shown that an ovary from an immature animal inserted into the tissues of an ovariectomised adult reaches maturity sooner than it would have done in its original environment a mature organ grafted into an immature produces no observable effects and becomes functionless A Lipschütz has obtained similar results when an ovary is grafted into a castrated male if the animal —guinea pigs were used—is an adult, hormonic effects, as shown by hypertrophy of the mammary glands, set in after 1½ 3 weeks, but if the animal en grafted is not fully grown there is a latent period of about six weeks ovaries from the same female may show these different latencies if grafted into males of different ages (*Jour Biol et Med Exper*, No 6, p 1, 1926) The grafted ovaries, however, do not usually show their normal periodicity, but enter into a state resembling prolonged œstrus

Y Tamura, working with mice, has, however, found evidence in some cases of the development of corpora lutea in grafted ovaries, the appearance of which suggested that they had been developed some time after the operation (*Proc Roy Soc Edin*, vol 47, p 148, 1927) He also found that the presence of the testis did not affect the vitality of the ovarian graft That ovarian regulation is at any rate partly somatic is further shown by the fact that removal of one gland leads to hypertrophy of the other, showing that some bodily factor limits the number of follicles which can come to maturity at any one time In this connexion it may be mentioned that T Tadokoro, M Abe, and S Watanabe have found differences between the proteins of certain tissues in male and female animals of various species (*Jour Facult Agricult*, *Hokkaido Imp. Univ*, vol 23, p 1, 1928)

[1] Continued from p. 915.

Recent work indicates that the anterior lobe of the pituitary and also the thyroid glands exert a definite influence on the ovary It has long been known that the former influences both bodily and sexual growth, and also that it hypertrophies during pregnancy, recent evidence suggests that at least two, if not three, different principles may be secreted by this gland, a growth promoting, one hastening ovulation and sexual maturity, and one inhibiting ovulation by stimulating the development of lutein tissue Precocious maturity in rats and mice can be provoked by injection of macerated aqueous suspensions of fresh anterior lobes, œstrus setting in after about three days acid extracts produce this effect in concentrations which have no effect on growth in an adult

The same hormone occurs in human placenta and the urinary secretion of pregnant women experiments on filterability and adsorption indicate that it possesses a smaller molecule than the growth promoting principle On the other hand, alkaline extracts of less fresh glands produce growth together with luteinisation of the ovary the follicles develop into corpora lutea without ovulation, and with enclosure of the ova, further ovulation is prevented This luteal tissue sensitises the uterus to stimuli, produces mammary overgrowth, and, developed during pregnancy, results in prolongation of this condition There is some evidence that the eosinophil cells of the anterior lobe of the pituitary are concerned with the stimulus to growth, whilst the basophils are in relation with the gonads (H M Evans and M E Simpson, *Jour Amer. Med Assoc*, vol 91, p 1337, 1928) It is to be noted that the hormones of the pituitary act through the ovary, in the absence of the latter none of the effects upon the secondary sex characters are observed The exact relationship between the anterior pituitary and the cyclic function of the ovary is not known, nor whether the secretion of hormones from the former is periodic.

The thyroid also has an influence upon the gonads,

but whether direct or secondary to its coincident effect upon the general metabolism of the body is not known G R Cameron and A B P Amies have shown that the administration of the dried gland to mice and guinea pigs leads to a prolongation of œstrus, especially in the latter, and also to prolongation of the whole cycle in the mouse (*Austral Jour Exp Biol and Med Sci*, vol 3, p 37 1926) Feeding fowls with thyroid produces changes in the plumage, which in males takes on a henny character (F W R Brambell, *Proc Roy Irish Acad*, vol 37 B, p 117 1926 M Nevalonnyi, *Bull de l'école super d'agronomie*, Brno, 1928) but Brambell considers that this effect is not physiological but due to the toxic results of the dosing, which produces hyperthyroidism Apart from this change in type thyroid feeding has the same effects in both sexes B Zawadowsky (*Jour biol méd expér*, vol 5, p 344 1927) has found that testicular degeneration in cocks and failure of egg laying in hens follows the administration of thyroid, again presumably a toxic effect

It may be remarked in passing that the secretions from both the anterior lobe of the pituitary and the thyroid gland are essential for growth and maintenance of normal health and any derangements will presumably affect the gonads just as the other tissues of the body on the other hand alterations of the œstrous rhythm may occur independently of other obvious bodily changes, suggesting that these glands may have a specific influence on the gonads or that the latter are more sensitive to their stimulation than the somatic tissues of the body

THE TESTIS

The male sexual gland is responsible for the development of the secondary sexual characteristics, as the ovary is in the case of the female Like the latter organ, it consists of cells from which the specific sex cells are developed and also of interstitial cells which lie between the seminiferous tubules it is generally held that the latter are the source of the hormone responsible for the appearance and maintenance of the secondary characters, since an organ in which the tubules have degenerated, such as an autotransplant, can still produce an internal secretion Testes always become functionless, so far as regards the formation of spermatozoa is concerned, when removed from the scrotum, either by transplantation or by fixation in the abdomen, and the same phenomenon is observed in naturally undescended organs, as in the case of unilateral cryptorchism in a rat described by W P Kennedy (*Jour Anat*, vol 61, p 352, 1927) The degeneration appears to be caused by the higher temperature to which the organ is exposed

On the other hand, some authors consider that the function of the interstitial cells is nutritive rather than internal secretory, basing their opinion on the histological appearances of these cells and on the presence in them of lipoid granules which are not specific in nature and may also occur in cells of the tubules which give rise to the spermatozoa (M Parizek, *Publ Biol de l'école vét*, Brno, vol 2, p 293, 1923 S Morgenstern, *Jour médico biol*, Fasc 4, p 29, 1925) In this case the internal secretion of the testis must presumably come from the external layer of cells of the seminiferous tubules which usually survive in a degenerated organ

The influence of the male gonads on metabolism has been followed after both castration and also the injection of testicular extracts In general, the results obtained so far have been rather inconclusive since they are irregular and slight in degree T C Shen and K H Lin have found no appreciable difference between the nitrogen excretion in the urine of eunuchs and normal men creatine was found in one case and the daily output of creatinine was variable in another, whereas normally creatine is absent and the creatinine excretion constant (*Chinese Jour Physiol*, vol 1 p 109 1927) Castration has no effect upon the level of the blood calcium (L Perelman *Jour medico biol*, Fasc 3, p 52 1925)

V Korenchevsky has investigated the effects of castration and injection of extracts of testis and prostate upon the metabolism of rabbits and dogs in a series of papers (*Brit Jour Exp Path*, vol 6, pp 21 74 and 158 1925 *Biochem Jour*, vol 19, p 772 1925 vol 22 pp 482 and 491, 1928) The development of obesity after castration does not always occur when it does it is accompanied by a decrease in both the nitrogenous and non nitrogenous metabolism there is little change in the metabolism if obesity fails to develop It is possible that these differences are due to variations in the response of the other internally secretory glands to absence of the testes Injection of prostatic extracts increases the nitrogen output in castrated but not in normal dogs, and a similar result was observed in the rabbit Injection of testicular extracts decreases the nitrogen metabolism Experiments on thyroidectomised animals indicated that the prostatic extracts acted on the metabolism by stimulating the thyroid gland whilst the effect of testicular extracts is similar to that produced by injections of insulin, so that part at any rate of the influence of the former is due to the presence of the latter hormone in the extracts, as confirmed by examination of their blood sugar reducing power

In the last two papers Korenchevsky has examined the influence of lipoid extracts and of watery extracts fractionated at various reactions atrophy of the secondary sexual organs in rats was not prevented by injecting these extracts, and the effects on the metabolism of rabbits were usually an increase in the nitrogen metabolism, provided that the thyroid gland was present It is doubtful how far these results can be ascribed to the presence of a specific hormone in the extracts maintenance of the secondary sexual organs in a functional condition in the castrated animal would appear to be a true index of the presence of a specific principle, and this has not yet been accomplished

In conclusion, a few words may be said on the subject of rejuvenation A critical investigation of Voronoff's experiments on the improvement of live stock has been presented by F H A Marshall, F A E Crew, A Walton, and W C Miller (Ministry

Agric and Fisheries, Board of Agric for Scotland) The investigators concluded that the methods of experimentation were not sufficiently critical to enable an answer to be given to the question of whether testicular grafting can improve the fertility of old stud bulls or the production of wool by the offspring of grafted rams In any event the economic importance of such experiments for Great Britain is probably only slight It is necessary to bear in mind that a testicular graft, to give satisfactory rejuvenation, must not only maintain the secondary sexual organs and characteristics in full function and exert the normal influence of the testis upon the cells of the body, but also stimulate the subject's own organ sufficiently to enable it to produce living spermatozoa the former effect can be produced by secretions from the graft, but only the subject's own testis can render him fertile Testicular grafting is a useful method of investigating scientifically the secretory function of the testis its usefulness as a practical measure must still be considered not proven

Obituary

PROF GEORG KASSNER

DR GEORG KASSNER, emeritus professor of pharmaceutical chemistry and chemical technology, died at Münster on Mar 30, 1928, at seventy-one years of age From the *Chemiker Zeitung* we learn the following particulars of his life A native of Lüben in Silesia, Kassner studied at Basel, Zurich, and Breslau, and received his first appointment in 1884 at Breslau under Prof Poleck In 1891 he was appointed professor of pharmaceutical chemistry and chemical technology at the University of Münster, where for thirty-five years he directed the training of students of pharmacy He also took an active interest in municipal affairs, and served for fifteen years on the Town Council In his teaching Kassner laid stress on the use of volumetric methods of analysis, and his methods were adopted in many other institutes

The work which Kassner had begun at Breslau led to a method of preparing oxygen from the air by means of calcium plumbate One of the chief disadvantages of this method was the fact that it involved the use of carbon dioxide, and when Linde's liquid air process was discovered Kassner recognised its superiority But, being convinced that further progress in the economical production of oxygen from air would be on chemical lines, he set to work to devise improvements, and in 1911 he succeeded in finding an inexpensive method of preparing both oxygen and nitrogen from air by means of plumboxan, a mixture of sodium plumbite and sodium manganate This process works at 400° C, a much lower temperature than was needed for his older process, and, moreover, the use of carbon dioxide was eliminated

During the War, Kassner discovered in the double compound of barium metaplumbate and barium manganate a useful catalyst for the atmospheric oxidation of ammonia to nitric acid at 500° C In addition to the work on lead compounds, he published numerous papers on other chemical subjects

DR E F J LOVE

THE University of Melbourne has suffered a loss in the death, on Mar 8, of Dr E F J Love, formerly senior lecturer in natural philosophy A brother of Prof A E H Love, he was born in Weston-super-Mare in 1861, he became a scholar of St John's College, Cambridge, and, after a short period as lecturer in physics in Birmingham under Prof Poynting, he was appointed to Melbourne in 1888 While he maintained a close interest in all branches of physics, his main interest centred in geodesy and thermodynamics In 1893 he published an account of a measurement of g at Australian stations, and at the time of his death he was secretary of the geodesy committee of the Australian National Research Council Dr Love was president of Section A of the Australasian Association for the Advancement of Science in 1907, when he spoke on the thermodynamics of the voltaic cell, and during his teaching work in the University of Melbourne he came to be recognised as an authority on thermodynamics Acoustics was another interest, and during the last few years he has applied the results of Sabine to the remedying of some local halls that had been acoustically defective He was president of the Victorian branch of the British Astronomical Association from 1899 until 1903 At the end of 1927 he retired from active teaching duties, and he then presented to the University a valuable collection of scientific periodicals and works on geodesy

WE regret to announce the following deaths

Prof Henri Andoyer, professor of astronomy at the Sorbonne in Paris since 1903, and an associate of the Royal Astronomical Society, on June 12, aged sixty-six years

Prof Franz Keibel, director of the anatomical and biological institute, Berlin, and a member of the Prussian Academy of Sciences, author of the "Normentafeln" of vertebrate development, and with Franklin P Mall of "Handbuch der Entwicklungsgeschichte der Menschen", on April 27, aged sixty seven years

Prof Charles Moureu, professor of organic chemistry at the Collège de France and an honorary fellow of the Chemical Society, aged sixty-six years

Mr Robert Ridgway, member of the National Academy of Sciences, curator of the division of birds in the U S National Museum since 1876, who was a past president of the American Ornithological Union and an honorary member of the British Ornithological Union, on Mar 25, aged seventy-eight years

Dr Charles E de Medicis Sajous, professor of applied endocrinology in the graduate school of medicine of the University of Pennsylvania, and president in 1917 of the American Association for the Study of Internal Secretions, on April 27, aged seventy six years

Mr M R Oldfield Thomas, F R S, for many years assistant in charge of Mammalia, British Museum (Natural History), on June 16, aged seventy-one years

News and Views

WE have received from Dr W G Woolnough, geological adviser to the Australian Commonwealth Government, some comments on the leading article in NATURE of Mar 2, dealing with the place of biology in school science This article, while stressing the unfortunate consequences of the neglect of biology in the schools curricula, pointed out that unless biology was approached through the medium of physics and chemistry the discipline of exact and critical thinking that these sciences confer might be seriously weakened Dr Woolnough believes that "it is the very inexactness of the 'biological' sciences which trains those habits of observation as opposed to manipulation, and which brings out the faculty of discrimination which is the essential of true scientific research" But this is only true provided the student has already some basis of observational and manipulative training on which to develop his faculty of discrimination, the whole point of the article was to show that physics, chemistry, and mathematics could not be displaced from this service by biology

THAT this is so is well shown by the actual illustration given by Dr Woolnough in support of his views After much experience in teaching microscopical petrology he has found the heuristic method most effective The meaning of such terms as refractive index, double refraction, cleavage, etc, is demonstrated to the students, who are then encouraged to make their own discoveries, aided only by a simple tabular guide and their text books But this method is only effective because the working material can be relied on not to 'play tricks' with the young student Cleavage and double refraction, for example, are definite physical phenomena a doubly refracting crystal does not suddenly change its mind and become opaque for a few days, whereas superficially erratic behaviour of this order is a commonplace in biology Had his duties been connected with biological instead of non biological instruction—with, say, mycology instead of petrology—he would have been brought up against this essential difference It is precisely because exact physical science is the foundation of Dr Woolnough's teaching methods that be is able to use the method at all

CORNWALL has produced many distinguished engineers and men of science, but none more worthy than Humphry Davy It was therefore very fitting that Penzance should do honour to her most distinguished citizen, who was born just opposite the spot where his statue now stands, and where the celebration was carried out At noon on June 8 the mayor and council of Penzance and the following Sir Humphry Davy Rolleston, Col R Humphry Davy and his wife, and R. Davy (descendants of the family), Sir Ambrose Fleming, representing the Royal Institution; Dr J Symons (president), E H Davison (secretary), and members of the Royal Geological Society of Cornwall; J C. Tregarthen (president), T R. Paull (secretary), and members of the Royal Institution of Cornwall, H Jenner and W L Fox (past presidents), E W Newton (secretary), and members of the Royal Cornwall Polytechnic Society, W E T Hartley, principal, University College, Exeter, and others met at St John's Hall, and walked in procession to the statue, where a platform had been erected, and in the presence of many thousands several speeches were made

THE Mayor of Penzance, Mr W G Goodfellow, said in the course of his remarks We are met here to-day to do honour to the memory of one of the illustrious sons of this borough Of the three learned societies of Cornwall responsible for arranging these celebrations, two of the presidents are Penzance men, born near this spot, as also was the case with Sir Humphry Davy himself Dr Symons and Mr Tregarthen then laid a wreath of laurel on the monument Dr Symons, speaking on behalf of the three learned societies of Cornwall, said that a former mayor, Dr Richard Pearce, on the occasion of his laying the foundation stone of the present Market House in 1836, remarked that the site of the assembly would ever be considered as memorable It was here that the greatest philosopher of the age first devoted himself to that science which rendered his name immortal, "Humphry Davy was born in the house just below, where he resided with his parents until they removed to Varfel, Ludgvan, when he was six years of age" It is somewhat a remarkable coincidence that the laying of this wreath should have devolved upon two who were born within a few yards of his birthplace, and who are now the presidents of two of the Royal societies of Cornwall Mr J C Tregarthen, speaking on behalf of the scientific societies of Cornwall, thanked the Mayor for the civic welcome and said that Davy's almost last words were "I have added some little to the quantity of human knowledge, and I have endeavoured to add something to the quantity of human happiness" A public meeting was held in the Pavilion in the afternoon, at which the speakers were Sir Humphry Davy Rolleston, Sir Ambrose Fleming, and others

MR R A WATSON WATT announced in his Symons Memorial Lecture to the Royal Meteorological Society (see NATURE, April 6, p 545) that current weather maps were to be broadcast from Daventry (5XX), and a specimen synoptic chart as received by wireless was reproduced in our columns Arrangements have been completed by the Meteorological Office, Air Ministry, the British Broadcasting Corporation, and Messrs Wireless Pictures (1928), Ltd, for the experimental issue from Daventry (5XX) of such weather maps by the Fultograph process between 2 o'clock and 2 25 P M on Tuesdays and Thursdays, and transmission commenced on June 18 The map will be prepared by the Meteorological Office and is similar in form to those published in the Press It shows the conditions over the British Isles and the neighbouring sea areas, and is not only of interest to many who receive the official forecasts and like to visualise the conditions on which they are based, but

should also be of great value to those who have sufficient knowledge of the weather to be able to base forecasts for their own locality upon it The great difficulty in the past has always been to get weather maps delivered quickly enough for practical use to be made of them Wireless transmissions will overcome this difficulty, and though during the experimental period the 7 A M weather map will not be broadcast before 2 P M , should the experiment prove successful it may be possible to arrange for an earlier transmission

THE publication of two volumes of the Annual Report of the Bureau of American Ethnology within a short period of one another emphasises the extent and value to anthropological science generally of the researches which are being carried out under official auspices in the United States In the interests of research workers in other parts of the world it is to be regretted that publication of these reports is much delayed Early publication of a record of results is most desirable even if that means postponement of comparative study In this matter the promptness with which the British Museum has published the results of its investigations in Honduras is worthy of much praise and also emulation by other official institutions In the present case the forty second Annual Report, which was the earlier to appear, carries us only to 1925 Much important work has been done since then The forty first Report, which has only just appeared, covers the work of five years from 1920 to 1924 Although it must be recognised that the permanent value of these volumes lies in the "Accompanying Papers", in which members of the staff record the result of their investigations, yet the brief introductory reports of the chief, Dr W J Fewkes, are of the greatest interest to those in other countries who wish for an authoritative survey of the general trend of investigations in American archæology and ethnology In the present instance in the years under review there has been a great increase in popular interest in the aborigines, and this has strengthened a movement to preserve as national monuments important ancient sites of aboriginal culture It is also to be observed that a sense of responsibility towards the Indian is growing, a gratifying if somewhat belated sentiment

IT is interesting to note how, in the years covered by the forty first and forty second Annual Reports of the Bureau of American Ethnology, the area covered by the work of the Bureau is being extended to wider fields A beginning has been made in examining and attempting to preserve such vestiges of the ancient culture of Alaska as have survived Within the United States themselves, the south western area, not unnaturally in view of its cultural importance, for long almost absorbed the resources of the Bureau Now, however, attention is being turned to the south east To the forty second Report Mr John R Swanton contributes two papers dealing with the Creek Indians and one in which he reviews the information relating to the aboriginal culture of the south east to be found in the writings of the early English, French, and Spanish writers, as well as the material collected by himself The late Mr William E Meyer, a lifelong student of Indian antiquities and culture, though not a professional archæologist, is the author of a study of Indian trails of the south east A paper by the same author on two prehistoric villages in middle Tennessee is included in the forty first Annual Report The Gulf area, which falls within this south eastern zone, is peculiarly important for American ethnology, as the earliest inhabitants appear to have been a brachycephalic type such as is found nowhere else in America A third extension which will be of much moment for the work of the Bureau in the future arises from its responsibility for work in Hawaii As a result of a preliminary survey of the Hawaiian material, made when the Pan Pacific Congress was held at Honolulu, it has been pointed out that the study of Hawaiian culture involves an extension to Samoa and other parts of the Pacific—a suggestion which has already borne fruit, for since the date of this report much valuable work has been done by American investigators in the Pacific This emphasises the reflection from which we started, that early publication of these reports is greatly to be desired

THE Faraday Society is arranging a general discussion on "Molecular Spectra and Molecular Structure", which will be held at the University of Bristol on Tuesday and Wednesday, Sept 24 and 25 A general introduction to the subject will be given by Prof W E Garner and Prof J E Lennard Jones The subject will be discussed in three sections, namely, band spectra in the visible and ultra violet, which will be specially introduced by Prof O W Richardson , the Raman effect, to be introduced by Sir C V Raman , and infra red spectra, which will be introduced by Prof C Schaefer in respect of solids, Prof J Lecomte in respect of liquids, and Sir Robert Robertson in respect of gases Papers have already been promised by Mr S Barratt, Prof G B Bonino, Prof J Cabannes, Prof W E Curtis, Prof P Daure, Prof I W Ellis, Prof V Henri, Prof E Hulthén, Dr R C Johnson, Prof V Kondratjew, Prof E F Barker and Prof C F Meyer, Dr A M Taylor, and Mr F I G Rawlins In addition, contributions are expected from Prof R T Birge, Dr H A Deslandres, Prof F Hund, Prof R S Mulliken, and Prof R W Wood

As in the case of recent successful discussions arranged by the Faraday Society, all the papers will be issued in advance proof, and the authors will be invited to devote a few minutes only to directing attention to points which they deem to merit special discussion, so that there will be adequate time for a lively general discussion By the kindness of the Council of the University of Bristol, members and visitors will be accommodated at the newly opened Wills Hall Particulars of arrangements can be obtained from the secretary of the Faraday Society, 13 South Square, Gray's Inn, W C 1 Cheap railway facilities will also be obtainable for those attending the meeting In view of the exceptionally large number of guests from abroad who will be attending this meeting, it is expected that there will be a

correspondingly large attendance of British workers The Society extends a cordial invitation to all those interested, whether they are members of the Society or not, and in particular invites research students to be present

The dangers attaching to ignorant treatment and working of different types of land are well known to the practical agriculturist The subject was discussed (*Daily News Bulletin*, Science Service, Washington, D C) by Mr Paul Redington, chief of the Bureau of Biological Survey, when speaking at the banquet of the Third New England Forestry Congress held in Hartford, Conn After alluding to the fact that much of their forest land is more profitable for producing wood and game animals, Mr Redington expressed the opinion that in the present era of agricultural depression through over production it is a mistake to increase the area of farm lands by draining and breaking up of swamps and shallow lakes "Too largely", he said, "in the past such areas have been looked upon as something merely to be drained to get rid of the water and make the land available for the production of farm crops and live stock In many instances this has reclaimed land that was utterly unsuited for such production, and at the same time it has destroyed it for uses to which it might have been more profitably devoted So long as there is more land available than is needed for agricultural and live stock production, which is the case in the United States, extensive drainage projects are, in my opinion, misdirected effort " From a different view point the caution applies with equal force to Great Britain We are not in the position of having more land available than is required for agricultural purposes, but it is not in doubt that considerable areas of undeveloped lands in the country will not respond to expensive drainage operations and become thereby of value for agricultural purposes The first step in the treatment of much of this land is by way of afforestation Drainage works with the latter object in view are comparatively inexpensive and will not involve the larger scale and excessively costly operations (with probable disaster as their outcome) which are now being announced in some quarters as a panacea for unemployment.

In the May issue of the *Journal of Chemical Education* C A Kraus and S T Arnold describe the results of an investigation into the training which chemists should have before entering chemical industry They visited a number of industrial and research laboratories in the United States and collected representative opinions from research directors and works managers From a collation of these opinions, it appears that graduates who propose to adopt an industrial career should have a thorough knowledge of general analysis, particularly quantitative, a sound working acquaintance with fundamental organic chemistry, facility in the use of English; and a reading knowledge of foreign languages, especially German Training in industrial chemistry and in engineering was not stressed, but it was felt that the student should have a reasonably good equipment in mathematics and physics, emphasis being laid upon the importance of thermodynamics There was little demand for a knowledge of the latest developments of academic chemistry, but the desirability of a year's post graduate research was urged by practically everyone Stress was also laid upon personality It would be interesting to know the views of English industrial chemists upon this matter, since a large number—probably the majority of graduates in chemistry at British universities enter the chemical industries, and it is clearly of great importance to the country as a whole that they should reach their maximum efficiency as quickly as possible Incidentally the foremost position assigned to analytical chemistry may be commended to the attention of science masters in the schools, where there is a noticeable tendency to cut down analysis to a minimum

Reference was made in our issue of Dec 17, 1927, p 890, to the Belgian National Fund for Scientific Research which was inaugurated at the centenary celebrations held that year of the famous Cockerill Works at Seraing According to the *Times* of June 12, within a year a sum of no less than £640,000 was given by some 1200 subscribers, and grants have been made to 30 engineers and scientific workers to enable them to carry on original investigation under their employers Subsidies have also been allocated to research students The romantic story of the Cockerill firm, which employs several thousands of workmen begins with the Lancashire mechanician, William Cockerill (1759–1832), who after some adventures in Russia and Sweden settled in Belgium in 1799 and entered into a contract to supply spinning machines, thus introducing into that country an industry of which England had previously had a monopoly It was his sons Charles, James, and John who in 1817 founded the factory at Seraing, John, in 1835, becoming the sole proprietor He died of typhoid fever while on a visit to Russia in 1840, but in 1867 his remains were removed to Belgium Owing to the German occupation, the centenary of the works could not be celebrated in 1917, but on the one hundred and tenth anniversary of their establishment important gatherings were held, and it was then that the King of Belgium made the appeal for the creation of the National Research Fund

A preliminary programme has been issued for the one hundred and tenth annual meeting of the Swiss Society of Natural Sciences The meeting will be held at Davos on Aug 29–Sept 1, under the presidency of Dr W Schibler, and the proceedings will be divided up among seventeen sections The programme includes lectures by Dr W Mörikofer, of Davos, on problems of meteorological radiation research, by G Bener, of Chur, on mountain road construction and science, by Prof R Staehelin, of Basle, on the physiology of high altitudes, by Prof E Guyénot, of Geneva, on the hypothesis of morphological territories in biology, and by Prof R Doerr, of Basle, on the submicroscopic forms of life Excursions to the Swiss National Park, to one of the institutes for the study of the physiology of high

altitudes, to the Davos observatory, and to other places of interest, are being arranged All correspondence should be addressed to the secretary, Dr W Mörikofer, Observatoire physico météorologique, Davos Platz The titles of communications for the sectional meetings should be sent in by June 30

THE Annual Report of the Imperial Institute for 1928 is a record of many useful activities in the investigation of agricultural and mineralogical problems, the answering of inquiries, and the promotion of various educational projects Among the investigations there may be mentioned the examination of Tasmanian stringybark pulp, which showed its value in the manufacture of artificial silk, tests which prove that Indian hemp is equal to European hemp in its resistance to fresh and salt water, the suitability for brick and tile making of clays from various parts of the British Empire, and the examination of many mineral specimens These are only a few examples of the kind of work which now engages the Imperial Institute, and they show its importance in research into the economic value of various parts of the British Empire

A DESCRIPTIVE pamphlet on the Hudson Bay Region, with many illustrations and maps, has been issued by the Natural Resources Intelligence Service of the Canadian Government The forthcoming completion of the Hudson Bay railway to Churchill, in providing a new route to a vast region, revives interest in the resources of this part of Canada After physical and historical introduction, the pamphlet continues with a description of the forests, minerals, water-power, and game Gold, silver, and copper zinc ores have been located and in some places are being worked The pamphlet, which contains no exaggerated claim for this part of Canada, is an interesting example of the way in which lands that were formerly little known were assumed to be of no value, but are now proving relatively attractive and at any rate not unworthy of considerable attention

THE seventh congress of the Far Eastern Association of Tropical Medicine, held at Calcutta in December 1927, was the subject of an article in NATURE of Mar 3, 1928 The *Transactions* of the Congress are now in course of publication (Calcutta Thacker's Press and Directories) in three large volumes, each of approximately 1000 pages, of which the first has already been received. The growth of the work done by successive congresses may be traced by the size of the *Transactions*, which has gradually increased in successive issues; those of the congress held in Hong Kong in 1912 were contained in a single volume of 399 pages, while those of the sixth congress held in 1925 in Japan required two volumes and 2313 pages The present volume comprises the proceedings of Sections I and II—the subjects of medicine and dermatology, pathology, surgery, ophthalmology, gynæcology and diseases of pregnancy, mental hygiene and psychiatry, radiology, dentistry, State medicine, general and special hygiene, and maternity and child welfare. Eighty-seven papers, many of great interest, with the discussions which followed their reading, are contained in the present volume, which is illustrated by 61 plates, mostly in half tone The editor, Lieut Col J Cunningham, is to be congratulated on the result of his labours The two volumes still to appear, which will contain the papers on such subjects as plague, cholera, leprosy, tuberculosis, bacteriology, protozoology, malaria, kala azar, medical entomology, helminthology, diseases of nutrition and deficiency diseases, immunology and chemotherapy, and rabies, promise to be even more interesting than the present one to the general scientific reader

A NEW volume of that comprehensive work entitled "Nauka Polska" (Polish Science), published by J Mianowski, Warsaw, for the Institute for the Encouragement of Scientific Works, has recently been issued This quarto volume of nearly 700 pages is the result of the collaboration of seventy five leading scientific workers, who have reported upon the means of organising and developing education and research in science subjects in Poland Much attention has evidently been devoted to a consideration of the immediate and future needs of the scientific institutions in the nation's various centres of learning, but public attention is also directed to the progress already made during the past decade "Nauka Polska" not only includes the natural and physical sciences and their numerous subdivisions, but also gives an account of work in Poland on psychology, criminology, aerodynamics, technology, geography, ethnology, philology, architecture, etc Interest has hitherto been most concentrated on the applied sciences, such as the technology of the metals It will be recalled that the president of the country, Prof I Moscicki, is himself a distinguished chemist and was formerly director of the Chorzow Fixation of Nitrogen Industry in Polish Silesia. Until recently it was not possible to form an opinion of the extent of the scientific work which was being conducted in Poland since investigators published their results in Russian or German journals Whilst this is no longer the case, one difficulty remains, namely, the fact that researches appearing in Polish publications only become known to scientific workers abroad through the various abstracting journals.

THE Herbert Spencer lecture delivered at Oxford on May 14, 1929, by Dr C. S Myers had for its subject "Psychological Conceptions in Other Sciences" (London Oxford University Press 2s net) The speaker is thus reversing the conventional practice of interpreting the 'higher' sciences in the language of the 'lower' There is a growing belief among physicists that it is impossible to predict what an individual atom or electron will do or which of the possible jumps of a quantum will occur next The psychologist, whose chief preoccupation has been with the individual, even when that individual was recognised as part of a group, has found mechanism everywhere, yet prediction with regard to the individual impossible. Dr. Myers in the lecture inquires how far knowledge of the mental world is helpfully applicable to the material world. He

reviews various problems, such as the distinction between primary and secondary qualities, estimation of weight and appreciation of colour, the intensity of sensations, and shows how, with the development of knowledge, ideas of the 'absolute' have been gradually replaced by those of the 'relative' Physics also has progressed along a similar path, and in place of the older notions of substance and absoluteness is finding itself occupied more and more with structure and entities in themselves unknowable and unimaginable The lecture is very interesting and suggestive and the point of view original It should prove stimulating to all scientific workers who are interested in the more ultimate problems of knowledge

The Huxley Memorial Lecture for 1930 of the Imperial College of Science and Technology will be delivered by Prof Graham Wallas, emeritus professor of political science in the University of London, on Monday, May 5, 1930, at 5 30 P M

A small earthquake was recorded at Kew Observatory on June 10 The first tremors reached the Observatory at 23 h 7 m 51 s G M T The shock originated under the Arctic Ocean about 200 miles from the Norwegian coast and about 250 miles from Tromso, near latitude 71° N, longitude 9° E A large earthquake was recorded at the Observatory on June 17 The first tremors arrived at 23 h 7 m 37 s G M T, and the epicentre is estimated to have been about 12,000 miles away

The Albert Medal of the Royal Society of Arts for the current year has been awarded by the Council, with the approval of the president, the Duke of Connaught, to Sir Alfred Ewing, Principal and Vice Chancellor of the University of Edinburgh, "for his work on magnetism and his services to technical education" The Medal was founded in 1863 as a memorial to Prince Albert, and is awarded each year "for distinguished merit in promoting arts, manufactures, and commerce"

At a meeting of the executive committee of the Imperial Botanical Conference (1924), held in London on Jan 18 last, it was decided to arrange a short Imperial Botanical Conference to be held immediately before the International Botanical Congress in 1930 The Imperial Botanical Conference, which it is intended should last only one day, will meet in London on Friday, Aug 15, 1930, at the Imperial College of Science and Technology, South Kensington, S W 7 The agenda before the conference will be purely of a business nature The proposal to hold a further Imperial Botanical Conference in 1935, on lines similar to that held in 1924, will be discussed, and, if necessary, the appropriate organisation for convening the conference will be arranged Reports of the committees which have dealt with the resolutions of the 1924 conference will be received

The January-March issue of *The World's Health* (Vol 10, No 1), the organ of the League of Red Cross Societies, is presented to readers in quarterly form as an experiment. A survey of the present position of leprosy is commenced in this number, with articles on leprosy in Japan, Siam, and Columbia

The Medical Directory Guide to "British Spas and Climatic Health Resorts" for 1929, edited by Dr R Fortescue Fox, has been issued by Messrs J and A Churchill, 40 Gloucester Place, W 1, price 1s In formation is given of the medicinal waters and spas of Great Britain and of marine and inland health resorts, with the clinical indications which may influence the choice of a particular spa or resort for a patient

The monthly publication of the Air Ministry known as the *Marine Observer* fills an important place in meteorological research with its copious notes supplied by observers at sea on various phenomena, and its abundant charts and illustrations A feature of recent numbers has been the general articles compiled at the Air Ministry on various aspects of marine meteorology These are valuable chapters, not only to sailors, but also to students The May issue contains a long article on the formation, occurrence, and prediction of fog, and another article on the local winds of the Mediterranean and Black Seas The April number had an account, illustrated by many charts, of the distribution of ice in the western North Atlantic, with special reference to the work of the United States *Marion* expedition in Davis Strait in the summer of 1928

We have recently received copies of a number of *Leaflets* issued by the Ministry of Agriculture and Fisheries, which have been rewritten in order to bring them up to date with advances in knowledge The *Leaflets* deal with various pests affecting agriculture and serve to keep the farmer and grower advised as to the best practical measures for controlling such enemies Apple capsids are of particular interest because they have only become serious pests during the present century, and a good deal of research has been, and is still being, concentrated upon them The latest *Leaflet* on the subject was rewritten in August 1928 and revised in January 1929 in order to bring to public notice the results of recent practical researches Other *Leaflets* deal with onion fly, slugs and snails, insecticides, and kindred subjects

A catalogue of books on chemistry and chemical technology has been issued by Messrs H K Lewis and Co, Ltd, 136 Gower Street and 24 Gower Place, W C 1 It contains particulars of a large number of books arranged under a very convenient system of classification

Messrs Francis Edwards, Ltd, 83 High Street, Marylebone, W 1, have just circulated a handsome illustrated catalogue (New series, No 2) of some 1000 books, pamphlets, and engravings relating to North America, which should be of interest and value to geographers and historians The catalogue contains facsimile reproductions of the title pages of many of the works listed, also bibliographic notes on some of the volumes

Messrs. C. Baker, 244 High Holborn, London, W C. 1, have sent us a copy of the new issue of their classified list of second hand scientific instruments (No 94) This list is now sent out twice a year only As usual,

the list contains a comprehensive selection of micro scopes and microscope accessories, and there is a large section on surveying instruments, which, it may be noted, are let out on hire Arrangements can also be made for hiring other apparatus Other sections deal with projectors, telescopes of various kinds, and various physical apparatus

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A junior assistant at the Forest Products Research Laboratory, Princes Risborough—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S W 1 (June 25) A geologist in the Geological Survey Office, Department of Industry and Commerce, Irish Free State—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (June 26) A junior lecturer in the department of pathology of the University of Liverpool — The Registrar, The University, Liverpool (June 27) A head of the school of engineering at The Polytechnic, Regent Street—The Director of Education, The Polytechnic, Regent Street, W 1 (June 28) An assistant lecturer in machine drawing and design in the engineering department of the County Technical College and School of Art, Newark —The Secretary, County Technical College and School of Art, Newark (June 29) A number of junior assistants at the National Physical Laboratory—The Director, National Physical Laboratory, Teddington (June 29) A wireless engineer under the Government of Nigeria for the Posts and Telegraphs Department—The Crown Agents for the Colonies, 4 Millbank, S W 1 (quoting M/1267) An assistant lecturer in the department of biology of the Huddersfield Technical College—The Director of Education, Education Offices, Huddersfield A lecturer in chemistry and physics in the school of pharmacy of the Merchant Venturers' Technical College, Bristol — The Superintendent, Merchant Venturers' Technical College, Bristol A lecturer in building and civil engineering at the Royal Technical College, Salford—The Secretary for Education, Education Office, Salford An assistant in the mechanical engineering laboratory of University College, London—The Secretary, University College, Gower Street, W C 1

Our Astronomical Column

THE TOTAL SOLAR ECLIPSE OF MAY 9 —Dr Baade, of Bergedorf Observatory, was stationed at Sogod in the Philippine island of Cebu He reports in *Astr Nach*, 5650, that cirrostratus clouds interfered with the photography of the outer corona, but very successful plates of the inner corona were obtained, which show its structure clearly Rev T E R Phillips exhibited at the meeting of the Royal Astronomical Society on June 14 some prints of the corona obtained by Dr R Waterfield at Iloilo, Philippines The extension shown on these was about one solar radius, but the negatives showed it a good deal further There appeared to be much less extension of the corona near the sun's poles than elsewhere, this is a familiar feature at sunspot minimum but less common near maximum

THE FUTURE OF THE SUN —The above is the title of the first of three articles by Dr Harold Jeffreys on geology and the related sciences to appear in the *Realist*, the first is in the June issue Dr Jeffreys notes that the hypothesis of the contraction of a great rotating mass of gas with an accompanying shedding of equatorial rings (originally propounded by Laplace and developed by Roche, Helmholtz, Kelvin, Lane) was held by many astronomers up to the beginning of this century, it was gradually discarded on two grounds, it gave an insufficient time scale, and there were grave dynamical difficulties in connexion with the moments of momentum of the sun and planets

Part of the contraction hypothesis was held until the year 1924, the dwarf stars were supposed to be those that had contracted beyond the point of continuing to have a purely gaseous constitution, so that by Lane's law their temperature would now decline Eddington then concluded by theoretical reasoning that the rate of radiation of energy should depend almost wholly on the mass of the star On plotting the stars of known mass he found that both giants and dwarfs lay on the same curve, and that the state of perfect gas continued much longer than was previously supposed, owing to the stripping off of the outer rings of electrons in the stellar atoms. A strong confirmation of the correctness of this conclusion was afforded by the demonstration of the great density of the companion of Sirius, which at the same time gave a proof of the shift of spectrum lines in a strong gravitational field which Einstein had predicted

The energy of stellar radiation is now ascribed to the conversion of the stellar matter into light and heat, the details of the process are still obscure, but it is conjectured that colliding protons and electrons may cease to exist as matter, becoming simply radiation The energy in the atom is so great that the possible life of the stars is extended from a few million years to many millions of millions The former contradiction between the estimated past duration of the sun and that of the earth has thus been completely removed

THE OPACITY OF STELLAR ATMOSPHERES —The Bakerian Lecture at the Royal Society was delivered on June 6 by Prof E A Milne on the subject of the opacity of stellar atmospheres He notes that the problem involves the study of the property of layers of gas, given the amount of the energy flux, and the intensity of the gravitational field it is further necessary to consider the effect of changing temperature in comparing the different spectral types, and the effect of absolute magnitude in comparing different stars of the same spectral type It is pointed out that there is no sharp boundary between photosphere and reversing layer, but that one merges into the other The solution of the problem depends largely on study of the contours of spectral lines, that is, on the determination of their intensities at different distances from the centre of the lines The method is applied to a zinc triplet in the spectra of Capella (bright component) and the sun, which are taken as a typical giant and dwarf of type *G*0 The absorption coefficient κ is found to be 300 for the sun and 60 for Capella Miss Payne found $\kappa = 150$ for *A* type stars, which is in satisfactory accordance Once κ is known the number of atoms above the photosphere can be calculated on certain assumptions for the different elements It is shown that the dependence of κ on the electron pressure *P* is confirmed by the fact that observation indicates an effect depending on absolute magnitude for stars both at low and high temperatures.

Research Items

Sex and Infant Mortality.—The difference in the mortality of the sexes during infancy is one of the most significant indications available of the constitutional factor in disease. During infancy the environment is uniform for both sexes, so that variation in the mortality rate between males and females may be attributed to variation in the sex response to environmental factors. From this point of view, Dr. Harry Bakwin has analysed the infant mortality throughout the United States registration area for the ten-year period 1915–1924 inclusive (*Human Biology*, vol. 1, No. 1, 1929). Male mortality far exceeded female under one year of age; to every 100 female deaths there were 130 to 134 deaths of males. The difference is not confined to the first year, but is most marked at birth and decreases with age until in the fourth year the death rate is about equal for the two sexes. But there are two exceptions to the gradual decrease: on the third day of life the mortality difference between the sexes is more marked than at birth, and it is also more marked during the second month than during the first. Since 1900 there has been a fall in infant mortality, but it would appear that relatively more females than males have benefited, for coincident with the common fall there has been a rise in the sex mortality ratio. There are seasonal differences in the ratio as well as regional differences, England, Wales, and Scotland having a high ratio, whereas it is low in Italy, Japan, Jamaica, and Spain. In rural communities, moreover, the ratio is lower than in city areas.

A Pre-Islamic God of Arabia.—In the *Indian Antiquary* for May, Ch. Muhammed Ismail figures and describes an image of the god Wadd sculptured on a stone now in the Prince of Wales's Museum of Western India and formerly in the possession of the Bombay branch of the Royal Asiatic Society. The importance of this image is that out of a large number of Arabian sculptures and stones with inscriptions mentioning the god Wadd, this is the only one of which the words purport to say that it is the image of the god Wadd. Owing to a misreading, a decipherment by James Bird in 1844 failed to identify it. Wadd was the most important of the pre-Islamic gods of Arabia, that is, of the peace-loving and commercial citizens of Himyar and Saba, who differed widely from the wild Bedouin. All ancient Arabs wore talismans bearing his name, and temples were dedicated to him as the god of love and happiness. His image has been described by an Arab commentator as that of a tall man wearing a loin cloth with another cloth over it, a sword hanging round his neck, and with a bow and a quiver, in front of him a lance with a flag attached to it. The present figure differs. The god is shown as a short man wearing a kilt. On his head is a close-fitting cap with a long tassel which seems to represent a strand of hair. Bedouins who come to Aden from the hinterland still shave the lower parts of the head, but keep a tuft or sometimes a long strand of hair on the crown. The author comments on the neglect of Arabian antiquities by the Indian Government in Aden and its hinterland, which is under its jurisdiction, but notes that, stimulated by Sir John Marshall's interest in field work, the Aden Historical Society is taking up this important subject.

Adaptations of the Pelvis in Marsupials.—The marsupials show so wide a range of habits that a comparative study of the pelvis in relation to function has, in the hands of Herbert Oliver Elftman, afforded some clear evidences of special adaptation (*Bull. Amer. Mus. Nat. Hist.*, March 1929). Much of the adaptation is associated with locomotion. Thus in arboreal forms there are largely increased muscles of adduction and a more open acetabulum allowing greater freedom of motion of the femur. Leaping forms, with their exaggerated hind limbs, require an elongated post-acetabular portion of the pelvis to provide leverage for the hamstrings, the ilium has an outward flare, and there is a large ilio-sacral angle. Fossorial adaptation depends on the particular method of digging employed by the animal, but in general the ischium is long, the iliacus attains great size and is thus partly responsible for the broadness of the ilium. The shape of the pelvis, however, is also associated with other than locomotor factors. The gross form is determined by its relation to the viscera. Its width is influenced by the width of the trunk. The size of the sacro-iliac angle and the position of the sacro-iliac joint are conditioned by the size of the erector spinæ muscle and the necessity for an adequate pelvic outlet. The marsupial bones assist the abdominal musculature in the support of the viscera and protect the pouch from distortion during the contraction of these muscles.

Differentiation *in vitro* of Cartilage and Bone.—Dr. Honor B. Fell (*Archiv f. exp. Zellforschung*, 7, 1928) records the results of observations on the differentiation *in vitro* of cartilage and bone. Cultures of embryonic limb cartilage from 8-day fowl embryos were made by the ordinary coverslip technique. The explanted limb cartilage enlarged greatly during cultivation, and in several specimens differentiated into epiphysial and diaphysial regions. After 10–12 weeks' growth *in vitro*, a proportion of the explants were in a healthy condition. Cultures of undifferentiated limb-bud mesenchyme from 3-day fowl embryos exhibited chondrogenesis although the tissue was spreading over the surface of the coverslip. Cartilage thus formed *in vitro* sometimes remained in a healthy state during three months' cultivation but underwent no differentiation into epiphysial and diaphysial regions. After 3–4 weeks' cultivation, ossification was observed in several cultures and the progress of bone deposition followed in the living explants.

Interrelationships of the Echinodermata.—An exhaustive discussion of the major systematics of Echinodermata, based on anatomical, embryological, and palæontological evidence, is offered by Prof. D. M. Fedotov, of the Russian Academy of Sciences (*Travaux du laboratoire zoologique et de la Station biologique de Sébastopol*, Série 2, No. 12, Leningrad, 1928). Pelmatozoa are regarded by the author as the group which has given rise to other Echinodermata. The sea lilies are derived by him from Cystoidea, while a discussion of the anatomical, embryological and palæontological evidence on sea urchins leads him to the conclusion that this group stands quite isolated amongst other classes of the Eleutherozoa, there being no definite grounds for suggesting a relationship between sea urchins, star fishes, and holothurians; the origin of sea urchins was probably in the Cystoidea Diploporita. Star fishes and ophiurs the author believes to have originated from the Edrioasteroidea, though there is no direct evidence in favour of this view. Holothurians are an exceedingly ancient group, dating back perhaps to Palæozoic times, and originated independently from sea urchins, star fishes, and ophiurs, but still must be considered as belonging to the Eleutherozoa.

ALIENS IN THE FLORA OF VICTORIA.—In an interesting note on the naturalised aliens in the flora of Victoria (*Proc. R. Soc. Victoria*, 41, 1928) Prof. A. J. Ewart states that in 1909 the number of aliens recorded was 363 and in 1928, 461. This rate of increase, slightly more than five per year, has been maintained with remarkable uniformity for the past sixty years. The aliens include the clovers, trefoils, medicks, most of the more valuable pasture grasses, and some garden plants that have run wild. Less than a hundred of the aliens are serious weeds, and few of them so serious a menace as the native bracken on newly cleared forest land. The transport of fodder is probably responsible for the relatively high proportion of aliens contributed by South Africa, which include some of the worst weeds. Prof. Ewart considers that owing to the competition of imported aliens and the pressure of settlement, probably less than half of the original flora (about 3000 species) will survive within fifty years and many originally widespread plants will be confined to special localities. Were it not for the disturbing factors introduced by man, the spread of the aliens might have been used as a test of Willis's age and area hypothesis. Among the interesting cases cited are: the evening primrose (1887) has covered less ground than the foxglove (1917), the musk weed *Myagrum perfoliatum* (1916) has become more abundant than the horehound *Marrubium vulgare* (1870), and the stinkwort, *Inula graveolens* (1893), rapidly overtook the stinkweed *Gilia squarrosa* (1887), both in area and abundance. Even taking species of the same genus, it appears that the time factor is of far less importance in determining the area covered by a species than its suitability to new habitats, its means of distribution, its aggressiveness and its resistance to foes and injurious agencies. "It seems probable that the age of a species is one of the least important of the factors governing its distribution, and that in only few cases can a relation be traced between the age of species and the area they cover at the present day."

JAPANESE HEPATICS.—The first part of what should prove an important series of papers upon the Hepaticæ of Japan, by Yoshiwo Horikawa, has appeared in the *Science Reports* of the Tôhoku Imperial University, vol. 4, No. 1, series 4. The author points out that more than 500 species are already reported for Japan, of which no less than 65 per cent are endemic. In the present contribution, species of two very interesting genera are described, *Makinoa* and *Schiffneria*. In the case of *Makinoa*, it is interesting to note that the constriction of the thallus, at the point where the sexual organs are developed at the close of the season, enables the different annual increments of growth to be distinguished. In this way six or seven years' growth contributions can sometimes be separated in the same specimen. Field observations of this kind upon the age of patches of liverwort seen growing in Nature are not very common.

THE KARAKORAM RANGE.—The *Records of the Survey of India*, vol. 22, contains Major K. Mason's account of his explorations in 1926 in the Shaksgam and Upper Yarkand valleys and the Aghil Ranges, with a map on a scale of 1 inch to 4 miles. The report contains a full illustrated account of his travels and a number of appendices on geology, natural history, etc. In discussing the nomenclature of the area, Major Mason points out that the term in general use, Karakoram Range, is a misnomer and that it means literally 'black gravel', and was first applied to the high pass on the route between India and Yarkand. From this pass the term came to be applied to the iciest range of mountains outside polar regions, on which the actual pass does not lie. Accepting the usage, however inappropriate it may be, Major Mason proposes to use the term Karakoram Himalayas to the whole mountainous area and to distinguish within it three main ranges. Of these the southern he proposes to call the Kailas Karakoram, the second he terms the Mustagh Karakoram, and the most northerly the Aghil Karakoram. To the north-east of this last range lies the Aghil 'Red' Range, which, however, Major Mason was unable to visit. The merits of this nomenclature are discussed at length in the report.

OIL WELL 1½ MILES DEEP.—Some idea of the astonishing progress of petroleum production engineering methods is obtainable from a record set up by an oil company operating in West Texas, U.S.A., which succeeded in drilling a successful oilwell to a depth of 8523 ft. below surface. Not only does this represent a wonderful engineering feat, but at one period a measured production of 1125 barrels of oil and an estimated production of some 12 500 000 cubic ft. of gas, indicate the discovery of pools of no mean consequence. The well formed part of the deep test programme at Big Lake oilfield, and was brought in towards the end of last year. In this region of Texas, known as "West Texas", a thick Permian limestone-marl and anhydrite series is exploited principally, but the depth of this particular well leads to the inference that Pennsylvanian beds (Upper Carboniferous) have been penetrated. It is noteworthy that of the 8523 ft. drilled, 2339 ft. represents 'open hole', $5\frac{3}{16}$ inch casing being set at 6184 ft. There is no reason why drilling should not be carried deeper so far as these data go, but the very high rock pressure at such depths would tend to exert a controlling influence, while the natural flow of oil and gas in the quantities stated implies similarly high fluid pressure. The temperature of the oil (flowing) was 49° F. The question has often been raised concerning the economic depth of ordinary drilling, attempts having been made to state a maximum beyond which cost of drilling and control would outweigh values yielded by the oil obtained; where pumping costs have to be added, the problem is further complicated. It would seem, however, that deep well drilling is an accepted policy to-day, and if in the future (when oil prices appreciate) the location of deeply buried pools, in fields already exploited for their shallower production becomes a matter of necessity, there is little doubt that this record will be broken, if it has not already been in the case of other previously projected deep wells.

EINSTEIN'S UNIFIED FIELD THEORY.—Mr. G. C. McVittie, in the June issue of the *Proceedings of the Royal Society* (No. A, 794), has provided a supplement to Einstein's somewhat abstract account of the new theory by showing in detail how it can be applied to a simple case. For an electrostatic field uniform in direction and nearly constant in magnitude, but with a slight exponential change of strength as we go along the field, it is possible to obtain exact solutions of the gravitational and electromagnetic equations of the older general relativity theory. These solutions are then substituted in the corresponding equations of the new unified theory. As a result it is found that the new equations are satisfied to the first order but not to higher orders. This shows clearly to what extent Einstein's new equations differ from his old ones. It will be recalled that in a letter to NATURE of May 4, p. 678, Prof. Levi-Civita outlined a modification of Einstein's new theory, with the object of obtaining exactly, and not merely to the first order, the older equations on a unified basis. Mr. McVittie would perform a useful service if he would exemplify Levi-

Civita's theory by applying it to the simple case mentioned above.

Radio Intensity Measuring Apparatus.—The utility of high frequency radio transmission systems and their extending use has created a demand for an instrument capable of measuring the strength of the magnetic field at any point. J. Hollingworth and R. Naismith read a paper on May 1 to the Wireless Section of the Institution of Electrical Engineers describing a portable apparatus suitable for measuring the absolute strength of the field produced by these currents. An instrument suitable for measurements of this kind can rarely be made by merely altering the electric constants of apparatus suitable for low frequencies. Resistance, capacity, and inductance are no longer constants at high frequencies. The set consists of a detector valve and a control valve. One stage of audio frequency amplification follows the detector, and a two terminal thermionic valve allows a galvanometer to be used for the signal comparison. A separate heterodyne is used to obtain the audio frequency. The instrument is capable of measuring the intensity of the magnetic field over a radio band of 5 to 12 megacycles per second. Without batteries it weighs about sixty pounds and so can be carried in a light car. The authors use an aerial connected to one end of a high resistance, the other end being earthed. The discussion of high frequency measurement aerial effective height, and wave attenuation all come into the problem. The method adopted, therefore, is to subject the instrument to searching tests for internal self consistency and then test it out of doors on local transmissions. The results enable the experimenter to determine whether the instrument is reasonably accurate or not. Experimental results are given showing the kind of accuracy obtainable. The work carried out by the authors is part of the programme of the Radio Research Board.

Boric Acids.—Various compounds of boric anhydride with water in different proportions have been described, but the only two boric acids definitely known in the solid state were orthoboric acid, B_2O_3, $3H_2O$, and metaboric acid, B_2O_3, H_2O. By means of vapour pressure determinations in the series B_2O_3–H_2O and measurements of the weights of water lost in passing from one part of the system to another, L. F. Gilbert and M. Levi have been able to show that probably there are eight compounds of the type nB_2O_3, H_2O, where $n = 1, 2, 3 \ldots 8$. This work is described in the *Journal of the Chemical Society* for March, and an approximate value for the heat of hydration of boric anhydride to orthoboric acid is given. This value differs considerably from previous ones, which are thought to be inaccurate.

Experiments with Carefully Dried Substances.—The *Proceedings and Transactions of the Nova Scotian Institute of Science*, vol. 17, Part 2, contains an account by D. McIntosh of attempts made to prepare carefully dried substances by employing low temperatures. A mixture of carbon monoxide and oxygen may be dried by cooling in a solid carbon dioxide–ether mixture, as was shown by Girvan, and after being kept in the freezing mixture for some hours cannot be exploded by an electric spark. The gas explodes, however, at about $-50°$, when there is about 1 molecule of water present in 40,000 molecules of gas. A similarly treated mixture of nitrous oxide and carbon monoxide always explodes at $-80°$. Other experiments on intensive drying by cooling were not successful, probably on account of the difficulty of removing the water film from the glass surface of the apparatus. Thus, the reaction between hydrobromic acid and ammonia could not be inhibited, although the vapour pressure of the water was reduced to one thousandth of a millimetre.

Non-Existence of Isomerism among the Dialkyltelluronium Dihalides.—Two forms of dimethyltelluronium dihalides were obtained by Vernon and from them two distinct bases, and he accordingly postulated the existence of two series (α and β) of isomeric compounds. He concluded that the tellurium atom had a planar distribution of valencies and suggested formulæ of the type

$$\begin{array}{c}\begin{matrix} I \diagdown & & Me \\ & Te & \\ Me & & I \end{matrix}\\ (\alpha\text{ di-iodide red})\end{array} \qquad \text{and} \qquad \begin{array}{c}\begin{matrix} Me \diagdown & & \diagup I \\ & Te & \\ Me & & \diagdown I \end{matrix}\\ (\beta\text{ di-iodide green})\end{array}$$

More recently this isomerism has been explained by assuming from the electronic point of view that the halogen tellurium linkages are non-equivalent (see NATURE, April 6, p. 547). In the *Journal of the Chemical Society* for March, H. D. K. Drew gives an account of a re-examination of the dimethyltelluronium di-iodides and dibromides and the two bases. He concludes that the members of the β series are not isomeric with the α compounds. The α compounds appear to be of normal type, are in general non-polar, and the tellurium atom in them probably has a tetrahedral distribution of valencies. The β compounds are complex substances resembling salts, but having the same empirical formulæ as the members of the series.

Preservation of Timber.—At the Glasgow meeting of the British Association, a paper was read by Prof. Percy Groom on the "Antiseptic Preservation of Timber" (published in *Empire Forestry Journal*, vol. 7, No. 2, 1928). In his paper Prof. Groom correctly states that the antiseptic preservation of timber is "usually regarded as merely a means of decreasing the damage done to timber by fungi (and insects); but when properly applied it can result in a positive increase of the available supplies of commercial timbers and thus be equivalent in effect, to increase of production and may thereby become closely linked with forestry." The author deals briefly with the losses incurred in the British Empire by decay to timber due to want of adequate preservation and the increased supplies which would result from a better economic utilisation of the available amounts. Such questions have received a great deal of attention at the Research Institute at Dehra Dun, where the first commencement in this line of research in the British Empire was made. Prof. Groom deals with his subject in a highly informative manner, and his paper should be studied by all interested in timber and its utilisation. What from the practical utility point of view, may be considered a side issue but one of considerable scientific interest, is the author's reference to the interaction of fungi and insects in the destruction of timber, a line of research which promises to be of considerable interest. Prof. Groom's theme did not include this study, but it is alluded to as follows: "The destruction of timber by fungi that cause rot and by insects that burrow into wood may be lessened by a *septic sanitation*, that is to say, by the adoption of measures designed to decrease the production of spores or eggs and to render the external conditions unfavourable to the activity of these organisms." Prof. Groom states that a combination of sanitation and antiseptic treatment gives the best economic results, but his paper is confined to the latter and omits a consideration of insects. His remarks on this subject are of interest.

The South-Eastern Union of Scientific Societies

CONGRESS AT BRIGHTON

THE thirty fourth annual congress of the South Eastern Union of Scientific Societies was held at Brighton on June 5–8, Sir Arthur Keith occupying the presidential chair in succession to Sir Martin Conway

In his address Sir Arthur took as his subject "The Pre Roman Inhabitants of Southern England" His endeavour was to trace the people of southern England from the coming of the Beaker folk about the beginning of the second millennium B C to the time of the arrival of the Romans The remains of the Beaker folk that have been found with the aid of the pick and shovel have possibly traced that race up to about a thousand years B C, and going backward from Roman times, the folk that Sir Arthur called the 'pit diggers' have possibly been traced back to 600 years B C Between these two dates there is a wide interval of which we seem to have no records, and it is this interval that archæologists are endeavouring to fill in Southern Englishmen of pre Roman times have been disinterred from time to time from the Downs of chalk, which show that they all had certain well defined common cranial characteristics, and they all have affinity to the Beaker folk who began to invade England from central and north western Europe some 2000 years before the Christian era

From the remains that have been found at Blackpatch, near Worthing, it is possible to infer what was the mode of life of these folk These early Downsmen grew their corn and ground it They domesticated certain cattle, such as the ox, the sheep, and the pig, and were no longer purely hunters They had looms The red deer they hunted and used the antlers as effective mining tools They fabricated flint implements of the same patterns as those from the neighbouring mines of Cissbury

Speaking of the finds of Beakor folk in the neighbourhood of Brighton, Sir Arthur first of all referred to the skeleton of a woman who had been laid to rest in a grave that was cut into when a trench was made for carrying a cable to a golfing club house on the east of Brighton The body was laid on its side with the limbs folded on the body There was also here the crouched skeleton of a child some two months old The oval pit in which they had been laid had been completed by covering it with a layer of flint cobbles Unfortunately there was no grave furniture, no coin, shard, metal, or ornament to show the date at which the woman and child "ceased to breathe the fresh air of the South Downs' Although her skull was of the long type, there were certain features that showed affinity to the Beaker type, a type that is known by its flat vertical occiput, its strong face with rugged features the eyebrows being usually very prominent and the forehead receding The type is still frequently seen in England, and it was stated that men of the type are often leaders in communities, Darwin himself reproducing its features

There appear to be two circumstances which give a clue to the identification of the Beaker people, the crouched position in which they are buried, and the covering of the grave with flint nodules Another burial was uncovered in north Brighton in which a woman was buried in a similar position, and although she was long headed there were traces of Beaker ancestry She is known as the Maycroft skeleton Another crouched burial was laid bare at Moulscombe pit, to the north of Brighton, where a male counterpart of the Beaker woman was found Another burial was discovered when the Ditchling Road was extended to the north, when a male skeleton was disinterred, but his skull was somewhat wider and his face shorter than the Moulscombe man In this case a beaker was found, of the kind used in England in the early part of the second millennium B C, and with it was a barbed flint arrow head under the skull Several other graves have been found of a similar nature

Sir Arthur then referred to the ancient flint mines of Blackpatch and the barrows nearby, whence the skeletons proved to be the same folk as the Brighton people One proved to have had a remarkable head It was not the typical Beaker head, for it was both long and wide, being 195 mm by 155 mm, and it has been thought that it represented a cross between long headed and round headed stocks The graves were destitute of grave furniture and the men were probably the miners who dug the flint mines close at hand A crouched burial of a man with all the characters of the Beaker breed was taken from a barrow on the heights above St Catherine's Point in the Isle of Wight On the Downs at Nunwell, 12 miles to the north, a skeleton was found in 1881, and the contents of this grave are preserved in the Carisbrooke Museum With it was buried a lugged pot like vase, which was thought by Mr Crawford to have been fabricated in the upper valley of the Rhine, possibly towards the end of neolithic times The trail of the Beaker men has been traced through Belgium into England and along the Kentish Downs, and in all cases the resemblance is great Sir Arthur raised the question as to whether the Beaker folk practised child sacrifice It may be that by coincidence a child died at the same time as the adult with which it was buried, but in quite a number of cases a child was buried with the adult, and this has been found to have been the case at Brighton, on Dunstable Down, in Belgium, and at Worbarrow Did the Beaker people sacrifice children to give youth to their dead, or was an adult sacrificed to guard the child in the realms to which it had gone? The Beaker blood appears to have been swamped as time went on by that of the ancient natives of England

Mr Hadrian Allcroft, in addressing the Archæological Section, asked the question as to what was the earliest church, and adduced evidence to show that a church was at first an open air enclosure, and was not a building at all It was really a burial place, and a walled in church was later than the burial ground in which it stood The Scotish Christianity from Ireland was introduced after the withdrawal of the Romans, and for many centuries looked with disfavour upon any church building of any kind The circular place of burial would enclose a few beehive huts for the monks, but no reference can be found that in the earliest days there was any place for united worship A Christian must be buried before the enclosure could become consecrated ground, and if Nature failed to provide this, the early Christians obtained a voluntary sacrifice of a human life In the case of the founding of the monastery at Iona St Oran volunteered to go to heaven, and was buried on the spot selected for the monastery

The excavations at Blackpatch, near Worthing, made by Mr J H Pull and Mr C E Sainsbury, were described by the former The position of this prehistoric site is on the borders of an old road running along a spur of the Downs 2½ miles west of Findon, at between 300 and 400 feet, O D Here was found a mine field containing a closely grouped series of pits sunk through the chalk until a seam of good flaking flint was reached in the zone of *Actinocamax quadratus* Many of the shafts were cleared

and low horizontal galleries were found at their base radiating therefrom Close at hand were open air hearths, sunken hut floors and a series of round barrows, and these barrows have yielded valuable evidence of the Beaker men who excavated the flint

Following the address by Mr A D Cotton, of Kew Gardens, on "The Importance of the Study of Systematic Botany", a paper was read by Dr Geo Morgan on wood nodules on trees, in which he made a clear distinction between sphæroblasts, or hard knobs of wood existing independently of the inside wood of a tree, and burrs or irregular excrescences from the layers of the wood Sphæroblasts or woody tumours appear to be in the vegetable kingdom a parallel to the tumours in the animal kingdom known as dermoids

Dr G P Bidder took "Death" as the subject of his presidential address to the Zoological Section He held that death was biologically a new thing relatively, and that senescence and natural death were not necessary attributes of life There is no such quality of protoplasm as inherent or intrinsic senescence That part of a living body that is not converted into protected spores, gemmules, or eggs is the body that undergoes the process of natural death There is reason to believe that the female plaice and certain anemones do not die, except by accident

The distribution of certain Sussex birds and insects was dealt with by Mr A F Griffiths Mr Reginald Smith gave a public lecture on "Early British Art", and showed that before the Romans came over the Britons had achieved a decorative art of the highest order It had its origin in classical art, chiefly of the Greeks of the age of Pericles, moulded by Roman influence later The artistic but warlike Celts had made a Greek settlement on the Rhine about 440 B C, and as at this time this country was called Britain it was perfectly correct to speak of Celtic art in relation to British discoveries found about that period

In the Geological Section, Mr Henry Dewey gave an address on "The Denudation of the Weald" and Mr Edward A Martin read a paper on "The Brighton Pleistocene Cliff Formation" The presidential address to the Regional Survey Section was read on behalf of Prof H J Fleure and dealt with various aspects of regional work and this was followed by a paper by Mr David Edwards, the Brighton Surveyor on "Town and Regional Planning"

The Congress included a reception by the Mayor, Alderman H J Galliers and a number of excursions were made to places of interest in the county

The Strangeways Research Laboratory, Cambridge

THE trustees of the Strangeways Research Laboratory, Cambridge (Sir Humphry Rolleston, Prof H R Dean, Prof Malcolm Donaldson, and Sir Charles J Martin), have issued an attractive little pamphlet setting out briefly the history of this remarkable institution Beginning in 1907 in a small house as a research hospital with three beds for the study of rheumatoid arthritis, it has gradually developed into a research institute devoted entirely to the study of tissue culture both in its general biological and its more strictly medical aspects Though still small and not too well endowed financially, it has now taken a leading place among the research laboratories This remarkable achievement has been brought about through the lovable personality, the selfless devotion, and the patient, persistent, careful work of the late Dr T S P Strangeways, who died two years ago Neither academic distinctions nor scientific honours came his way, but no scientific man could wish for a finer reward than to have his name associated with an institution such as this laboratory

Although radium is being used more and more extensively in the treatment of cancer, its use is still almost entirely empirical, for until recently little was known of its mode of action on either the normal or the malignant cell This was one of the problems which had engaged the attention of Dr Strangeways during the last few years of his life, and by applying radium to cells cultivated *in vitro* and following the subsequent effects under the microscope in the living cell, he and his pupils have succeeded in obtaining information which has thrown a new light on this obscure problem, and has revealed the inadequacy of some of the *a priori* conceptions current among clinical radiologists

The beautiful kinematograph films of Dr Canti which many of our readers may have seen and admired were made in collaboration with the Strangeways laboratory This and other work is being continued and it comes rather as a shock to find from the trustees' report that up to the present neither the director nor any research worker has received payment from the funds of the institution "This gift of service has in most cases been rendered possible only by the aid of fellowships or research grants from other sources The tenure of benefactions of this kind is, however, limited to a few years, and if the excellent work which is being carried out at the Strangeways Research Laboratory is to continue and the foundation remain in its present form—a monument to the unselfish enthusiasm of its originator—its income must be increased sufficiently to enable it to provide salaries for a small permanent staff"

The staff consists of five research workers, with Miss Honor Fell as chief of the laboratory This year a course of instruction in the technique of tissue culture will be given at the laboratory on July 9–Aug 10 Since only a limited number of applicants can be received, notification from those wishing to take the course should be sent not later than June 30 to Dr H B Fell, Strangeways Research Laboratory, Cambridge

Sugar Beet in England

THE progress of the sugar beet industry in England has been followed with the closest attention since 1924, but the interest naturally increases with the approach of the end of the term of years during which the Government subsidy is in operation The question which confronts the English farmer is not whether the crop can be grown in England, but whether it can be grown *profitably* when faced with the competition of the open market. Experiments of various kinds have been carried out in different parts of England to make a thorough investigation as to the best methods of cultivation, manuring, and harvesting, and at the same time the continental procedure has been closely studied in order to make the best possible use of their longer experience It seems generally clear that profits can be made at the present time (about £5 per acre being quoted as an average from one area for last year), but the closest co operation must be

built up between the growers and the factories, and costs still further decreased, before the industry can safely be regarded as self supporting Improvements made by the farmer will be of little avail if the crop is not marketed economically

A comprehensive review of the situation is given in the 'Report of the Second Sugar Beet Conference", held at Harper Adams College, and also in an article by E C Pretyman in the *Journal of the Royal Agricultural Society*, vol 89 It seems generally agreed that beet can be grown on a number of soils, but that the best crops are obtained on a deep soil there must be no deficiency of lime Seed should be sown plentifully on a carefully prepared seed bed in late April or early May, a dressing of dung if possible having been given to the preceding crop or in the previous autumn, though artificials can usually be applied with advantage instead Early singling is of the greatest importance, the distance between the plants not exceeding ten inches the spacing between the rows should be the smallest possible to allow of thorough cleaning Lifting should take place as soon as the crop is ripe usually from mid October to mid November, in order to obtain the maximum sugar content In this respect the continental farmer is at an advantage in that his crop matures earlier than in England

As regards harvesting implements, the ordinary lifting plough appears to be as suitable as any looseners' employed on the Continent, and the fundamental factor on which economic marketing depends seems to be efficient organisation of harvesting operations, rather than on the introduction of expensive machinery Labour is the chief item in the grower s costs Generally speaking this is both more plentiful and cheaper in Germany and Belgium than in England, a large proportion of the work being done by well organised gangs of labourers which travel round the country If the beet is grown 'in shift', that is, in place of the ordinary root crop such as mangolds, the farmer in England has probably no need to obtain outside labourers, and in this way his costs are kept low On the other hand, his acreage and therefore his returns are also limited, and if at some distance from a factory transport introduces heavy charges Co operation alone provides a solution to these problems

The question of improving the percentage sugar content in the beet is as yet imperfectly understood, but an increase in tonnage lies more in the farmers hands and is certain to bring in a larger return Returns can also be appreciably increased by an intelligent use of by products, in fact the financial success of the beet crop may depend on it The tops as well as the wet or dry pulp available at a low price from the factory, are valuable as cattle food, and the continental farmers invariably make full use of them for this purpose Reduction in factory costs is all important for the success of the industry Heavy expense is incurred owing to the factories lying idle except during a few months in the autumn and winter, and if the extraction process could be continued throughout the year an appreciable reduction in costs could be made A new system is now on trial at the Eynsham factory with the view of achieving this by means of subjecting the beet to a drying process It is claimed that the dried slices or cossettes' can be stored without undergoing deterioration or loss in sugar content but the method has still to be proved before any far reaching claims can be made for it

The future of the industry in England cannot yet be predicted, but there seems no reason why it should not prove successful if every effort is made to reduce costs to a minimum, and to secure the closest co operation between the grower and the factory

Jubilee of the Hellenic Society

ON June 24 the Society for the Promotion of Hellenic Studies will celebrate the fiftieth anniversary of its foundation On the afternoon of that day a commemorative meeting will be held in the Stationers Hall Ave Maria Lane, at 3 P M The chair will be taken by Mr Arthur Hamilton Smith president of the Society, who will deliver his presidential address Prof Gilbert Murray has promised to speak, and addresses and greetings from friendly and allied bodies will be presented In the evening of the same day a festival dinner will take place at the Criterion Restaurant at which Mr A Hamilton Smith will preside The guest of the evening will be Lord D'Abernon who will propose "The Prosperity of the Society", a toast in which he will be supported by Sir James Frazer The reply has appropriately been entrusted to Mr George Macmillan, honorary secretary of the Society from 1879 to 1919, and now honorary treasurer, to whom the Society has been deeply indebted throughout its history for his unceasing activity on its behalf

When the Hellenic Society, as it is familiarly, if incorrectly, called, was founded in 1879, the extent and character of the influence it was to exert in humanistic studies could scarcely have been foreseen Not only was the trend of the political situation at that time obscure, it was also necessary that those who controlled the Society should be at some pains to define its activities in order to remove an impression from the mind of the public to whom it hoped to appeal, that its aims were not exclusively literary Accession to its numbers was rapid and influential At the second annual meeting the council was able to announce a membership of nearly four hundred, while the first page of the original candidates' book reads like a scholars' roll call with such names as Canon Seddon, Dr Donaldson, J R Green J E C Welldon Rev J A Magrath, and Robinson Ellis, to name a few only In regard to the scope of its activities, there is no side of the life and art of ancient Greece on which it has not touched but above all it has earned the undying gratitude of the scholar and historian by the way in which, both as a body and through its individual members, it has fostered research in the prehistory of the Eastern Mediterranean

Within the years of the life of the Society, Sir Arthur Evans, always one of its most prominent members, has revealed an entire civilisation second to none in importance in the history of human culture More directly, perhaps, is gratitude due for the active interest taken by the Society in the foundation of the British School of Archæology in Athens, the practice ground of a distinguished line of British archæologists and scholars The foundation of such a school was the subject of discussion in the council from the early days of the Society This bore fruit in the opening of the School in 1886 Fittingly enough one of the two memorial volumes to be issued in connexion with the anniversary deals with the excavation of the sanctuary of Artemis Orthia at Sparta carried out by the School, and is edited by Prof R M Dawkins, a former director The second volume, by Mr George Macmillan, is a history of the Society

University and Educational Intelligence

CAMBRIDGE —The Ministry of Agriculture and Fisheries has informed the secretary of the School of Agriculture that a grant not exceeding £3000 has been sanctioned by the Empire Marketing Board for the provision of buildings to investigate the use of B C G vaccine in the protection of calves against tuberculosis

Dr Marshall has been reappointed reader in agricultural physiology

Mr F P Ramsey, King's College has been reappointed University lecturer in mathematics

The electors to the Isaac Newton Studentships give notice that an election to a studentship will be held early in the Michaelmas Term 1929 These studentships are for the furtherance of advanced study and research in astronomy

EDINBURGH —Sir Alfred Ewing, who is retiring from the principalship of the University, and Lady Ewing have received warm testimony of the esteem in which they are held in Edinburgh On June 11 a portrait of Sir Alfred was presented to the University and a replica to Lady Ewing at a large gathering of subscribers in the Upper Library Hall The presentations were made by the Lord Provost, and Sir John Gilmour, Lord Rector of the University, accepted one of the portraits on behalf of the University The portraits, by Mr Henry Lintott R S A represent Sir Alfred in his robes as Vice Chancellor On June 14 at a great gathering in the M'Ewan Hall gifts from the students were presented to Sir Alfred and Lady Ewing who, on leaving the hall, were accorded a great demonstration and were drawn in a decorated carriage by way of Princes Street to their house in Moray Place On June 18 the members of Senatus entertained Sir Alfred at dinner in the Senate Hall Lady Ewing has also received a gift from the wives of the members of the staff of the University

The resignations are announced of Dr R Stewart MacDougall, reader in agricultural zoology, who has been responsible for the teaching in agricultural and forest entomology since 1906, and of Dr John Stephenson, lecturer in zoology (invertebrates) since 1920 and formerly professor of zoology and principal of Government College, Lahore

MANCHESTER —The Council has accepted a gift of £1500 from Messrs Benger's Food, Ltd This amount, together with a previous gift of £500 from the same source, is to be devoted to the furnishing and equipment of the new laboratories for pharmacological and pharmaceutical chemistry, which will bear the name of the "Benger Laboratories"

The Grisedale scholarships for biological research previously of £100 each, will in future be combined in one annual scholarship of £200 In the present year two scholarships of £200 will be offered, and application must be made to the Registrar not later than June 22

DR LEWIS F RICHARDSON, who is in charge of the Physics Department, Westminster Training College London, has been appointed Principal of Paisley Technical College

THE Royal Commission for the Exhibition of 1851 has made the following appointments to the five Senior Studentships offered for award in 1929 —On the recommendation of the University of Cambridge Mr F P Bowden (Tasmania), for research in physical chemistry, Mr C S Hanes (Toronto), for research in plant physiology, Mr M L E Oliphant (Adelaide), for research in experimental physics, Mr B Woolf (Cambridge), for research in biochemistry, all at the University of Cambridge On the recommendation of the Imperial College of Science and Technology Dr W F Whittard (London and Cambridge) for research in geology and zoology at the Imperial College of Science and Technology

THE National Congress of Parents and Teachers in the United States, which had in 1928 a membership of 1 279 000, is engaged in a strenuous campaign for promoting child welfare through the stimulation of parental interest and sense of responsibility In the December issue of *School Life* an account is given of one of its activities known as 'the summer round up of the children', the essential features of which are (1) A physical examination on or before May 1 of all children who will be due to enter school for the first time in the following autumn, (2) the application during the summer of appropriate treatment for remediable defects and (3) a second inspection in the autumn to ascertain the extent to which the defects have been corrected The aim of course is to ensure for as many children as possible a fair start on their school career Begun in 1925, this enterprise has been successful whilst maintaining the closest relation and most helpful co operation with the regular health agencies in securing the personal activity of the parents Clearly the parents thus early aroused to the need of preventive and corrective measures are likely to continue to take an intelligent interest in such matters—and this view has been abundantly confirmed An investigation made after the first of these round ups indicated that less than 3 per cent of the children examined were not in need of remedial treatment The campaign has the support and co operation of the United States Bureau of Education the American Medical Association, and other important bodies and numerous doctors dentists, and nurses give their services freely in the examinations

THE Report on the work of the Department of Petroleum Technology of the Sir John Cass Technical Institute for the session 1928–29 has just been issued While differing but little from that of the previous session, in so far as the schedule of work and organisation is concerned it is clear that steady progress is being maintained and that the particular body of men for whom the courses are specially designed namely those engaged in clerical and administrative branches of the industry, is deriving a considerable benefit therefrom The necessity for co operation between industry and educational authorities has been sufficiently voiced ever since the War, in a recently published Board of Trade report, this policy is re-emphasised and each great industry is enjoined to 'make its own educational needs the subject of thorough and systematic examination' While the oil industry as a whole can certainly be acquitted of any charge of neglect on this score the Sir John Cass Institute has gone more than half way in giving practical expression of the desire of the academic world to do its share There can be no possible excuse for any non technically trained man in the industry who desires to widen his knowledge and thus to better himself if he does not take full advantage of such instruction as is here provided The chief subjects covered during the session were general technology of petroleum, chemical and physical properties methods of examination of oils and the applications of engineering It is satisfactory to note that two most important subjects were included in the work of this session 'Developments in Lubrication" and "Geophysical Methods as applied to Oil finding" This in itself is sufficient testimony to the thoroughly modern character of the curriculum and, incidentally, significant of the value attaching to the policy adopted by the Governors for the past eight years, that of keeping in close touch with prominent men in the industry in its several specialised branches

Calendar of Patent Records

June 23, 1789.—General Henry Seymour Conway, nephew of Sir Robert Walpole, and Secretary of State from 1765 until 1768, was granted a patent on June 23, 1789, for utilising the waste heat from coke ovens and conveying it through pipes "for the working of steam engines the baking of bread, meat, or other food, the calcining and fusing of ores and metals, the making of brass and steel, as also for the purpose of warming rooms, staircases, large buildings, and for heating water."

June 24, 1738.—The patent granted to Lewis Paul on June 24 1738, includes the earliest example of cotton spinning by roller drawing, the specification describing a process in which the prepared sliver having been passed through one set of rollers, "a succession of other rowlers, cillinders, or cones, moving proportionately faster than the first, draw the sliver into any degree of fineness which may be required." There is, however, very little evidence to show that this part of the invention was ever put into practical operation, and the main credit for the introduction of roller spinning must be given to Sir Richard Arkwright.

June 24, 1856.—The system of interlocking railway points and signals was the invention of John Saxby, of the L. B. & S. C. R. and was patented by him on June 24, 1856. The advantages of the new system were at once recognised and it was generally adopted. Works were started by Saxby first at Haywards Heath and then in London, and branch factories were opened in Brussels and Paris.

June 25, 1761.—An early attempt at the manufacture of the parts of watches by machinery was made by George Sanderson watchmaker, of Exeter, who was granted a patent for his invention on June 25, 1761. On the same date, June 25, a year later, a second patent was sealed to Sanderson for a "lunar and calendar watch key", in which a calendar mechanism in the key was caused to advance one day by the act of winding the watch. According to Britten, keys on this plan were made by Etienne Tavernier of Paris at the end of the eighteenth century.

June 26, 1799.—The first self acting carding machine for making wire cards for preparing wool and cotton was patented by Amos Whittmore and Clement Sharp of London on June 26, 1799. The machine bent and cut the wires, pricked holes in the leather, and inserted the teeth into the holes by one operation, but the cards produced by it were too coarse to supersede the hand made cards in Great Britain, where the art had been brought to great perfection. The inventors therefore took their machine to America, where it proved very successful owing to the lack there of efficient card makers. Afterwards, the patent was acquired by the American, J. C. Dyer, who so greatly improved the machine that he was able to reintroduce it into Great Britain and to establish a considerable trade. His improved machine was patented in 1811.

June 27, 1838.—The successful production of seamless brass and copper tubing is due to Charles Green, of Birmingham, whose patent for the process was granted on June 27, 1838. The invention, similar to John Wilkinson's earlier process for making lead tubes, consisted in drawing a thick tubular ingot, the internal diameter of which was approximately the same as that required for the finished tube, until it had been reduced to the requisite thickness. The inventor proposed to use on his drawbench four rollers arranged at right angles, the periphery of each being hollowed out so that when brought together a complete circle was formed.

Societies and Academies.

EDINBURGH

Royal Society, June 3.—**W. C. M'Intosh**: On abnormal teeth in some mammals, especially in the rabbit. In the Primates the chief irregularities are the development of extra molars, the narrowing of the tip of the lower jaw so that the incisors and canines are crushed from their normal positions, asymmetry of the muzzle, gaps between the teeth, and bulging of the rows of grinders internally or externally. In the Carnivora, gaps between the incisors in the maxilla and mandible, displacement and duplication of canines and duplication of incisors are found. In forms suffering from peridentitis salivary calculi occasionally occur. Displacement of a canine may be accompanied by an aperture in the hard palate into which the tooth fits. About twenty Rodents other than rabbits have been found with abnormal teeth, amongst which striking cases exist in the beaver, hare, and the brown rat, the right mandibular incisor in the former making more than a circle and penetrating the soft parts. In the teeth of the sperm whale the dentine and cement may be diseased and abraded. The folding of the root of the small tusk of the female dugong is noteworthy. In the Ungulates and marsupials numerous abnormalities present themselves. Special attention was devoted to the rabbit, abnormal teeth in which were described in about 100 cases and grouped temporarily into (1) those with the upper incisors more or less symmetrically curved outward, (2) upper incisors deflected to one side, (3) upper incisors curved into the mouth. The old view of such dental abnormalities being due to external injury must be abandoned, since in every group congenital causes or diseases were usually at the root of the abnormalities.—**Ian Sandeman**: Bands in hydrogen related to the Fulcher system. The $3^3S \rightarrow 2^3S$ system of Richardson and Das is extended, the band previously given as the null band (0, 0) now being taken as (2, 0), while two additional vibrational levels are added on the infra-red side.—**J. A. V. Butler** and **W. O. Kermack**: The action of salts of polynuclear bases on colloidal suspensions and on the electro capillary curve. In small concentrations, salts of 5 : 6 benz 4 carboline and its derivatives effect precipitation of colloidal gum benzoin and other negatively charged lyophobic colloids, but when higher concentrations are used no precipitation occurs and the colloidal particles acquire a positive charge. Experiments on the precipitation of colloidal gum benzoin by mixtures of benz-carboline and gelatin indicate that the presence of the gelatin tends to decrease the adsorption of the benz carboline. Benz carboline sols, present in low concentration ($M/20,000$), exercise a marked effect on the electro capillary curve of mercury, the depression being maximum on the positive side of the maximum of the primary, that is when the mercury is positively charged relative to the solution. The results indicate that benz-carboline ions undergo marked adsorption even on a positively charged surface.—**Sir Thomas Muir**: The theory of skew determinants and pfaffians from 1891 to 1919.

DUBLIN

Royal Irish Academy, June 10.—**R. Lloyd Praeger**: Report from the Fauna and Flora Committee on recent additions to the knowledge of the fauna and flora of Ireland. The report deals with recent progress in our knowledge of a large number of Irish animal and plant groups, and where a previous comprehensive report has been published, it gives a detailed account of all additions.—**R. Lloyd Praeger**

Sempervivа of the Canary Islands area with special reference to hybrids The paper was mainly the results of four months' work in the Canary Islands in 1927, and dealt especially with the occurrence of numerous hybrids among the species of *Sempervivum* which form so marked a feature of the vegetation of that region —**J Kaye Charlesworth** The glacial retreat in Iar Connaught The glaciers of the ice centre of Iar Connaught overrode the western part of the Central Plain of Ireland, and on their retreat deposited the marginal accumulations about Lough Corrib and Lough Mask On the inner side of these moraines there lies a wide zone devoid of moraines This zone is followed by the central area of the submontano and cirque moraines of the local glaciation of Iar Connaught They probably denote a new advance of the ice **J J Drumm, R J P Carolan, and Hugh Ryan** The constitution of iso catechin tetramethyl ether Iso catechin tetramethyl ether was prepared from chloro catechin tetramethyl ether by indirect hydrolysis It consisted of colourless crystals melting at 121° 122° C whereas catechin tetramethyl ether melts at 146° 147° C The preparation of iso catechin tetramethyl ethyl ether and of iso catechin tetramethyl methyl ether are also described Both of these are optically active but differ markedly from catechin tetramethyl ethyl ether and catechin tetramethyl methyl ether respectively in optical activity and melting point The racemic form of iso catechin tetramethyl ether and of iso catechin tetramethyl methyl ether could not be obtained by the reduction of the respective ethoxy and methoxy pyrylium colour bases which latter together with chloro catechin tetramethyl ether were first produced by Drumm (*Proc R I Acad* **36**, B 5 (1923) p 46) The work is in agreement with that of Freudenberg (*Annalen d Chemie*, 1925 446, 87) who has shown that in the preparation of the chloro catechin tetramethyl ether of Drumm (loc cit) a pinacoline transformation takes place involving a wandering of the veratryl group with consequent formation of an $\alpha\beta$ diphenyl propane derivative , catechin itself being an $\alpha\gamma$ diphenyl propane derivative —**J J Drumm, Sheila M Maguire and Hugh Ryan** 3 4 Dimethoxy benzyl 3 5 dimethoxycoumaranone The previous work of Drumm, MacMahon and Ryan (*Proc R I Acad* , **36** B (1924), p 154) had shown that the reduction of veratrylidene 3 5 dimethyoxycoumaranone by means of hydrogen in presence of platinum black gave rise to a dihydro compound, in the formation of which latter compound it was assumed the veratrylidene double bond was reduced, leaving the carbonyl group untouched It is now shown that in the above reduction the carbonyl group is unaffected, for on treatment with phenyl magnesium bromide, a colourless crystalline carbinol is obtained, melting at 82° 83° C This carbinol on bromination in the ordinary way yields a monobromo derivative melting at 115° C

Paris

Academy of Sciences, May 13 —Guido Ascoli The approximate representation of functions —**J Delsarte** The Fredholm transformations rendering invariant a quadratic functional —**Coulomb** A formula of quantic algebra —**Fahir Emir** A new determination of the thickness of a film of oleic acid in the state of saturation on water and of the saturation pressure of this film The experimental results given agree well with those of Marcelin as regards the thickness of the saturated film, but the figures for the saturation pressure are definitely lower The causes of the difference are discussed The film has the same thickness on distilled water and on weak ($N/20$) hydrochloric acid —**Pierre Auger** The theory of the photo electric effect The formula recently deduced by A Sommerfeld gives a distribution formula in good agreement with experiment —**Mme and M Lemarchands** The constant of equilibrium in double decompositions in aqueous solution A study of the reversible reaction $BaSO_4 + 2HCl = H_2SO_4 + BaCl_2$ From the equilibrium constants at 18° C and 100° C and the application of the van t Hoff equation, a figure for the heat of reaction is found which agrees within the limits of experimental error with the direct thermochemical determination —**H Colin and A Chaudun** The concentration of the sugar and velocity of hydrolysis in acid solution —**Mlle Suzanne Veil** The ferromagnetic properties of the ferrites —**Ch Bedel** Some conditions of solubility of silicon in hydrofluoric acid Hydrofluoric acid in the presence of oxidising agents (potassium permanganate chromic acid ferric chloride hydrogen peroxide) dissolves silicon readily The nature of the metal forming the containing vessel also exerts an influence on the rate of solubility **Swigel Posternak and Théodore Posternak** The configuration of inactive inosite —**Georges Mignonac and Odd W Rambeck** The action of cyanogen chloride, bromide and iodide on the sodium compound of ethyl malonate The syntheses of ethano tetracarboxylic acid and ethylene tetracarboxylic acid The cyanogen halides do not react similarly Sodium ethyl malonate in ether solution gives mainly ethylmalonic ether with cyanogen chloride replacement of the latter by cyanogen bromide gives a mixture of the ethyl ethers of ethylene tetracarboxylic acid and ethane tetracarboxylic acid The latter substance is the sole product when cyanogen iodide is used **Mme Ramart-Lucas and F Salmon-Legagneur** The comparative stability of isomers from their absorption spectra (Dehydration of glycols isomerisation of ethylene oxides)—**L Royer** The corrosion of a crystal of dolomite by an active isotropic liquid A comparison of the corrosion figures of dolomite produced by active and by inactive organic acids shows that the result is affected by both the optical symmetry of the crystal and by that of the acid **Jean Chevrier** The daily variation of the electrical potential of the air and of electrical loss during the month of September 1928 at the Observatory of Ksara (Liban) —**Paul Becquerel** The latent life of pollen grains in a vacuum at −271° C Pollen grains (*Antirrhinum Nicotiana*) after drying over caustic baryta were placed in a tube from which the air was removed as completely as possible with a Langmuir condensation pump and then sealed up The tubes were placed in liquid helium (temperature −269 to −271 7C) for seven hours and kept for five months The germinating power remained unaltered by this treatment, although similar grains preserved in dry air for seven months lost their germinating power —**Raymond-Hamet** Pharmacological applications of the technique of the kidney transported to the neck —**René Fabre and Henri Simonnet** The physical and biological study of the dextrorotatory sterol isolated from beer yeast The slight curative effect (anti rachitic) observed with irradiated zymosterol is regarded as probably due to traces of ergosterol left in the product in spite of careful purification —**Edouard Chatton and Mme M Chatton** The conditions of conjugation of *Glaucoma scintillans* in lethobacterial cultures The direct and specific action of certain zygogen agents —**H Pénau and G Tanret** A dextrorotatory sterol of yeast, zymosterol Details of the method of preparation from yeast, purification, analysis, physical and chemical properties The alcohol is not simply isomeric with ergosterol as it contains two hydroxyl groups and has the formula $C_{27}H_{40}(OH)_2$ —**H Jacotot** The preparation of a

hyperactive serum against cattle pest —**V Zernoff** An attempt at serotherapy in *Galleria melonella* The injection of the blood of vaccinated larvæ produces a curative effect, and this curative property of the blood of vaccinated larvæ may be preserved for several days *in vitro*

Rome

Royal National Academy of the Lincei, Mar 3 —**G Fubini** The canonical pencil —**G Armellini** The horizontal diameter of the sun in 1927 and 1928 Measurements of the horizontal diameter of the sun during its passage of the meridian, made at the Campidoglio Observatory by various observers, give the following mean values for the past few years 1924, 16′ 1 03″, 1925, 16′ 0 63″, 1926, 16′ 1 02″, 1927, 16′ 1 54″, 1928, 16′ 1 58″ —**A Comessatti** Galois' curves (2) —**G Scorza-Dragoni** Integrals of the equation, $y'=f(x, y)$ —**G Krall** Local limitations of dynamic effort —**A Wundheiler** A generalised displacement in Riemannian spaces In a paper published last year, Gerhard Thomsen described applications of a new notion of parallelism in Riemannian spaces, termed the Fermi parallelism The latter is defined by certain properties, which lead to a formula worked out by Thomsen in the particular case when the displaced vector is orthogonal to the curve of transport In the present paper the general formula for this displacement is derived —**G Vitali** The centres of curvature of the geodetics of a variety It is shown that, if P is a point of a variety V_n of n dimensions, in which the σ_2 of V_n has $n+\nu$, $\nu=(n+1)/2$ dimensions, the centres of curvature in P of the ∞^{n-1} geodetics of V_n issuing from P are situate on a hyper sphere K passing through P of the linear space S_ν of ν dimensions lying in σ_2 and perpendicular to Vn —**F Lamberti** Two particular dynamic equations of a linked material system —**Gabriella Armellini Conti** Colorimetric observations made during the total eclipse of the sun on June 29, 1927 A series of photographs, taken at Ringebu (Norway), of a polychrome screen exposed to the sun's light confirm the red coloration of the light apparent during the eclipse —**L Martinozzi** The electrical characteristics of meteorites (the hypothesis of an electrical origin of their luminosity) and a limiting value for the density of the ions in the upper atmosphere Burgatti (1927) has advanced the view that the luminosity of meteorites may be of electrical origin A simple calculation, made on the basis of certain assumptions, of the electrical charge necessary to a meteorite in order that bombardment of the ions present in the zones traversed may render it luminous, leads to somewhat high values for this charge and hence for the corresponding potential Taking into account the fact that the charge should be negative, the values found are not easily explained, since, as Burgatti pointed out it would be more reasonable to expect that meteorites would become positively charged by photoelectric action, nothing is, however, known concerning the distribution of potential in the universe The necessary value calculated for the number of ions per c c agrees well with the number required for Heaviside's reflecting layer —**E Amaldi** and **E Segrè** The theory of the Raman effect The mechanism of the Raman effect proposed by Smekal and generally accepted would indicate that Raman lines corresponding with very intense infra red bands should be also very intense Observations have failed to confirm the existence of any such relationship, and it is now shown that the experimental results are in complete accord with the theories of Schrödinger and Dirac, and that with any Raman line there corresponds, not necessarily an infra red absorption band, but simply the difference between two terms, only when, by chance, such two terms combine directly will an infra red line exist —**L Fernandes** Investigations on sulpho salts (8) Persulpho salts —**G Malquori** The system $Fe(NO_3)_3-KNO_3-HNO_3-H_2O$ at 25° —**F de Carli** The double carbonate of cobalt and potassium The double salt, $CoCO_3, K_2CO_3, 4H_2O$, may be completely dehydrated by heating it at 120° in a current of carbon dioxide Measurement of the dissociation tension at various temperatures, and application of Nernst's approximate formula, give for the heat evolution corresponding with the equation, $Co+1\frac{1}{2}O_2+C=CoCO_3$, the value 169 43 or 163 13 Cal, according as the heat of formation of CoO is taken as 63 80 or 57 59 Cal Calorimetric determination gives the value 173 31 Cal —**A Pieroni** Naphthophenoxanthones $\alpha\beta$ Naphthophenoxanthone cannot be obtained by the general reactions serving for the preparation of the $\beta\beta$ and $\beta\alpha$ isomerides, possibly owing to the ready elimination of the carboxyl in the α position of the naphthalene nucleus, but is formed when α benzoyl β naphthol is heated with aluminium chloride for 2 hours at 150°, it crystallises in golden yellow needles melting at 173°, and its solution in sulphuric acid is yellow and shows an intense green fluorescence —**T G Levi** 1 3 5 Dithioazine (formothialdine) This, the first member of the thialdine series, has not previously been described It may be obtained, together with trithioformaldehyde, by treating aqueous formaldehyde solution with sulphur or, better, ammonium hydrogen sulphide —**Giulia Martinez** Heulandite from Monastir —**R Grandori** Symbiotic micro organisms in the egg of *Pieris brassicæ L*

The New Museum Outlook

THE museums of Great Britain are bestirring themselves, or, if that be putting it too strongly, at any rate many men of action and foresight are bestirring themselves concerning the museums There is a museum feeling in the air But in the midst of the reports and commissions, addresses and discussions which express this activity, the plain man may be excused if he fails to see that criticisms, suggestions and counter suggestions all point to a broad but tolerably well defined road by which the museums of the British Isles must endeavour to make their way The new road is the focus of many independent paths along which progressive museums have been feeling their way in recent years, often in face of difficulties, and scarcely realising that they were *taking part in one of the great educational* movements of the times Though the reports have scarcely emphasised the magnitude of the change, it means a radical recasting of the museum idea and the adoption of a fresh museum outlook

Here we propose to outline the fundamental change in outlook which progress demands and to inquire whether recognition of the new objective may lead to suggestions for the development and control of existing museums

In their historical origin, museums were simply conservatories, in the basic meaning of the word, houses for the storing and safe keeping of whatever was thought to be worth keeping, and their officers were and are keepers That is still looked upon as the primary and fundamental purpose of museums, and yet it is only in a few of the largest museums that the material is of a value so great or nature so irreplaceable that its conservation is of first and last importance In the second stage of their development, museums condescended to show some of their possessions to favoured visitors and finally to the public, but they placed the specimens just as they were accustomed to store them, in the arrangement most convenient for reference by experts It is not so many years since a keeper in one of the national museums gave instructions that *British birds (and that in a British museum) should* be labelled with their Latin scientific names only The attitude, and it was widespread, was that the public might learn if it could, but it was no purpose of the museum to teach

That almost all the natural history collections in the museums which possess them are still arranged on the systematic lines of the expert taxonomist, is a relic of an early development, a convenient grouping for reference, easy for the museum officer

to arrange, and capable of infinite expansion Educationally, however, it is a passive arrangement It permits the visitor, if he is receptive, to gain certain impressions of form and of relationship, but it is not designed to thrust new ideas upon him, to compel him to consider and reconsider In a general way that is typical of the old museum attitude to education , hitherto the museum has been an inactive educator, allowing the visitor to sip where he would, or go away dry if the nectar was not to his taste, but never, by one wile or another, compelling him to drink of the stimulating cocktails it might concoct

The new outlook which underlies the recent discussions regarding the museums of Great Britain, and towards which a few bright exceptions have been striving is that museums must henceforward make it a primary duty to take an active and progressive part in the educational systems of the country In a short preface to an American work dealing with the relationship between the American Museum of Natural History and the Educational authority of New York,[1] Prof Henry Fairfield Osborn stated that the growing museum influence, which during the past quarter of a century has been especially remarkable throughout the cities of the United States, is largely due to the recognition that the museum is not a conservative but a progressive educational force, that it has a teaching quality or value peculiar to itself, that the museum succeeds if it teaches, fails partially if it merely amuses or interests people, and fails entirely if it simply mystifies

If only this could be set as an aim and end in the forefront of museum activities, the museums of Great Britain would take on a fresh lease of activity, and create for themselves a new and powerful place among the social institutions of the country, in no less degree than they have done in the United States of America

In an address delivered a short time ago to the Royal Society of Arts and referred to in NATURE (Feb 9, p 227), Sir Henry Miers sketched in broad outline the ways in which museum collections might be brought into relationship with educational stages He founded his proposals on the assumption that museums should cater for four classes of visitors For the ordinary visitor the history and resources of the town or district should be displayed , school children and students of riper years require summary collections and introductory series , for the collector and serious inquirer systematic collections are needful , and the researcher must have at hand great stores of classified material for investigation and comparison

Even this passive arrangement of museum exhibits falls short, however, of the needs of an active educational policy, such as the times demand, and such as has been attained by many of the museums in the United States As typical of these, glance at the activities, almost violent activities our sedate institutions would regard them, of the museums of the Brooklyn Institute of Arts and Sciences In the course of a single year ten special exhibitions of various art collections and eight exhibitions of prints were arranged and exhibitions of motion pictures portraying the Chronicles of America ' and zoological subjects, as well as lecture courses for the public, for teachers and for students were held In addition the Institute has specialised in a Children s Museum ', with loan exhibits of natural history specimens for schools, with schools visits helped by three teachers assigned by the Board of Education, summer field trips, lectures, and so on The detail with which the educational side is organised is indicated by many little refinements, such as the small cases of mounted birds which a child may borrow and take home as he would a book, the files of five thousand pictures and of trustworthy magazine articles, so catalogued that any set may be selected and borrowed by child or teacher, and the loan series of eight thousand lantern slides

Is it desirable that the museums of Great Britain should reach towards such a goal? And if it is, is such a goal attainable ? The consensus of opinion amongst educationists, the efforts already being made by the more progressive museums in this country, and the views expressed in or underlying recent reports and discussions, all point to the desirability of some such development, if museums are to escape from the backwash of stagnation and move with the main stream of the nation's progress It may be said that the proper purpose of the great national museums is rather to attend to scientific interests than to cater for the education of elementary school children, but the argument is sufficiently met by the actual development of the American institutions, which have satisfied the demand for intrusion into educational affairs without losing a whit of their scientific enthusiasm or reputation

The question as to whether this desirable end is attainable is not so easily answered Our opinion, however, is that it can be realised, but not under museum conditions as they generally exist in Great

[1] Free Nature Education by the American Museum of Natural History in Co-operation with the Department of Education of the City of New York , by G H Sherwood 1920

Britain to day An analysis of the difficulties will suggest lines along which development might well take place

There is the fundamental difficulty of staffing The teaching of young and old is an art based upon scientific principles, definitely recognised and the subject of specialised courses in universities and training colleges It cannot be expected that the curators of museums, whether they be chosen for their general knowledge or for their expert skill in particular branches of science, can be at the same time, barring a few exceptional cases, in close touch with educational developments and the needs of elementary, secondary, and advanced education Even if they knew the demands, they cannot be expected to be familiar with the technique and progress of modern educational methods

It is evident, therefore, that a scientific museum staff is not best fitted for the carrying out of an educational policy, quite apart from the fact that in the larger museums the scientific staff is already overburdened with its own particular problems If the museum share in educational progress is to be more than a mere nibbling at the fringe of a great problem, new qualifications and new personnel must be drafted into the scheme Moreover, this change must take place with as little disturbance of existing arrangements as possible, for it is recognised that, for the purposes which they now serve, the greater museums are working competently and smoothly There must be no uprooting of a well-established growth, the educational shoot must be grafted upon the present sturdy museum plant

These considerations suggest one or two broad lines of change which might well herald the adoption of an active educational policy There must be a mutual approach between the museum body and the educational body This *rapprochement* would develop in two directions, one affecting the framing of general museum policy and the other the actual development of the policies decided upon In the first case, the governing body of the museum, whether it be an *ad hoc* committee of the county or municipality, the council of a naturalist society, or an advisory body of whatever origin, would be strengthened and broadened in outlook by the inclusion of one or more of the leading educationists of the district, selected for their capacity in dealing with new problems as well as for their knowledge of educational needs It would be strange indeed if, on such a body, discussions between men of general culture, educational specialists, and representatives of the museums themselves did not evolve new suggestions worthy and capable of being carried out

The carrying out of the schemes so formed leads to our second consideration On one hand museum staffs must co operate with educational authorities, and on the other, educational authorities must make more use of museums On the lowest scale, this implies that exhibits of museum materials will be arranged in such a way that they can be used, simply and easily, to illustrate the Nature study lessons of the schools, and that school authorities will support the effort by making full use of the museum But on a higher scale, and in the large museums, it would imply much more, as the activities of the Brooklyn Museum foreshadow The large museum would play its part by appointing a staff specifically to deal with educational activities, the educational authorities would detail certain of their teachers to conduct school parties in the museum, give museum lessons, and so on

In whatever way it may be accomplished and whatever degree of development it may reach, the closer association between museums and formal education is an end eagerly to be desired, it would inevitably lead to fresh lines of usefulness for museums already flourishing, and might spell a new life for many institutions now all but moribund The passive, dead and alive museum is like a bank which, having collected the moneys of its customers, exhibits a few samples of currency in its windows and locks the remainder in its strongholds It is not the receipt and storing of money or of specimens, but the use made of them, that means success for bank or museum That is, in effect, our plea for the deliberate adoption, in museums large and small throughout Great Britain, of the new museum outlook

Mathematical Physics

Mathematical and Physical Papers By Sir Joseph Larmor In 2 volumes Vol 1 Pp xii + 679 Vol 2 Pp xxxii + 831 (Cambridge At the University Press, 1929) £6, 6s net

THESE volumes contain the contributions made by the author to different scientific societies and periodicals during a period of nearly half a century, and the subjects treated of extend to almost every branch of physical science The author observes in his preface that "every investigator bears the stamp of the domicile in which he has been brought up" In the present case there are two domiciles, to the first is probably traceable the influences of Hamilton and MacCullagh The

second, beginning at Cambridge towards the end of the period which saw the rediscovery of Green's work, the publication of Thomson and Tait's "Natural Philosophy", and the publication of Maxwell's treatise on "Electricity and Magnetism", has also had its influence, both in the selection of the subjects of investigation and on the method of treatment

One of the outstanding events of the period was the recognition of the importance of the Lagrangian method as the means of investigating not only the problems of mechanics but also the problems of physical science in general The memoir by Green on the reflection and refraction of light is possibly the earliest in which the conditions for the successful application of the method to a physical problem are set out clearly, although not infrequently too much trust has been placed in his statement—"that but little effort is required on our part"—while the caution implied in the earlier part of the passage quoted from is overlooked

By 1880 the value of the method in the investigation of the problems had been fully recognised, and had become the usual method of investigation for these problems The method naturally plays an important part in the present collection In the paper "On Least Action as the Fundamental Formulation in Dynamics and Physics" (*Proc Lond Math Soc*, 1884) the method is applied with success to a great variety of problems both in mechanics and physics and the mathematical connexion between them is established The same method is applied to the problem of "the flow of electricity in a system of linear conductors", leading to a very general solution of the problem In the first 400 pages of the first volume there are papers on subjects in pure mathematics, optics, and electricity of varying length and importance, but all of interest The British Association Report (1893) on 'The Action of Magnetism on Light, with a Critical Correlation of the Various Theories of Light Propagation" gives an account of the different theories which had been proposed to account for the phenomena accompanying the propagation of light up to the time of its preparation, and compares them carefully, at the same time making various suggestions and removing some of their obscurities This report is the forerunner of the series of three papers "On a Dynamical Theory of the Electric and Luminiferous Medium" published in the *Philosophical Transactions*

The first of these papers appeared in 1893, and its central feature is the identification of the electric energy function with the energy function developed by MacCullagh in relation to optical phenomena This energy function had been arrived at by adopting a procedure which was the converse of the procedure adopted by his predecessors

The elastic solid theory of light propagation as developed by Green, Cauchy, and others had provided an adequate representation of the phenomena of the reflection and transmission of light in the case of isotropic media but had failed to give results which were in agreement with Fresnel's results in the case of anisotropic media Green and Cauchy had proposed to overcome this difficulty by the introduction of extraneous forces MacCullagh set out to discover the energy function which would satisfy Fresnel's laws both for isotropic and anisotropic media Later, Kelvin showed that the energy function built up by MacCullagh was that of a quasi labile elastic medium or of a gyrostatically loaded medium, hypotheses which are not unrelated to the hypotheses of Green and Cauchy In the author's paper of 1893, this energy function having been identified with the electric energy function is applied and tested for a great number of different phenomena In particular the result is obtained that the velocity of propagation of light is affected by a magnetic field Experiments carried out by Sir Oliver Lodge showed that the effect, if any, is so small as to be incapable of detection Two conclusions can be arrived at as the result of these experiments, either the luminiferous medium is fixed or stagnant, or the energy function which leads to this result is defective The author has chosen the first of these alternatives, but it may be observed that the direct application of Faraday's laws to the problem of the effect of a constant magnetic field on the velocity of the propagation of light gives the same result as these experiments, namely, that there is no effect

The problems of magneto optic rotation and radiation are discussed on this theory, and with the introduction of a dissipation function, the circumstances of the reflection of light by metallic media are investigated

In an appendix the theory of electrons is introduced and applied to some of the cases, in particular, the theory of natural magnets is treated from this point of view, and also optical dispersion In the second paper (1895) the theory of electrons is developed to a greater extent, and is applied to the investigation of the phenomena which depend on the molecular or atomic properties of material media In addition to the phenomena discussed in the first paper, the propagation of light in metals, conduction currents, the mechanical electro-dynamic

forces acting on a conductor the problems of a conductor rotating in a symmetrical magnetic field and the conjugate problem of a rotating electrified conductor are considered as also the pressure of radiation The null result of the Michelson Morley experiment is discussed on this theory and explained in terms of what is now usually referred to as the Lorentz transformation

In his memoir La théorie électromagnétique de Maxwell et son application aux corps mouvants (1892) and in a later memoir (1895) H A Lorentz developed a theory of electrical and optical phenomena similar to the theory presented in the present volumes The energy function which is fundamental in both cases is the same and although the treatment more especially where statistical processes are involved is somewhat different the results obtained when the phenomena discussed are identical are naturally for the most part in agreement The particular form of the transformation arrived at in the case of a material body moving with a uniform velocity from which the later development known as the theory of relativity has arisen is an inevitable consequence of the form of the energy function which is the basis of the theory of a stagnant ether but there are difficulties connected with this theory which so far do not appear to have been surmounted For example is the Lagrangian method applicable to the comparison of two systems when the space co ordinates of the one involve the time co ordinate of the other and the time co ordinate of the first involves the space co ordinates of the second? Furthermore it has been proved that if Faraday s laws are applied to the case of a material body moving with a uniform velocity the axes of reference for Faraday s laws being the same as the axes of reference for the moving body the relation between the moving body and a body at rest relatively to the same axes is that the moving body is contracted in the ratio $(1-u^2/c^2)^{\frac{1}{2}}$ in the direction of its motion and no transformation involving the time co ordinate is involved

In the third paper of the series the theory of electrons is restated and its application to material media is more extensively developed The investigations of the two previous papers are revised in some cases the relation of the theory to the kinetic theory of gases and to radiation is investigated a general theory of optical dispersion is set out and the problem presented by absorption bands is discussed Thermodynamics osmotic pressure the laws of chemical equilibrium para magnetism and diamagnetism are also discussed and the mechanical relations of radiation are re investigated

Whatever the ultimate verdict on this theory of the ether which is the basis of these papers (afterwards with additions and revisions embodied in the author s Æther and Matter) may be it offered a possible and promising line of advance it is in agreement with a greater number of physical phenomena than its predecessor the elastic solid theory of the ether and the author s contributions to it are very notable There are subsequent papers on other applications of the theory the Zeeman effect the optical influence of a magnetic field etc all additions of interest to the subject

There are several papers on geophysics an interesting paper on Huygens principle various reports and addresses but probably the most important papers in the collection other than the electrical papers are the papers on thermodynamics and the theory of gases The author has expressed a doubt as to whether the time is ripe for the formulation of a history of electrical theories this despite the many treatises on thermodynamics and the kinetic theory of gases is true in some measure of the theories connected with these latter subjects These volumes however contain valuable contributions in this direction and in a connected form would go far to supply such a history

A detailed examination of the different papers in the two volumes is impossible within the present limits but it may be observed that they contain contributions of interest and value to most of the questions which have been prominent in physical science for the last half century By collecting them together so as to make them readily accessible to other scientific workers the author has earned their gratitude and the care with which they have been edited and printed reflects great credit on the author and on the Cambridge University Press

One Hundred Years of the 'Zoo

Centenary History of the Zoological Society of London By P Chalmers Mitchell Pp xi + 307 + 33 plates + 9 plans (London Zoological Society of London 1929) 25s

BY its Zoo is the Zoological Society of London known to the people its zoological gardens have given it a hold upon the nation which no purely scientific activity could have gained and the progress of the Zoo is the touchstone by which its success will be tested at any rate by the superficial Yet from the outset of its career two distinct and almost antagonistic aims lay at the hearts of

the founders of the Zoological Society and were embodied in its charter on one hand the popular appeal of the introduction of new and curious subjects of the Animal Kingdom and on the other the sternly scientific advancement of Zoology and Animal Physiology It is perhaps the greatest triumph of its hundred years of existence that the Society has cherished these two objects with equal favour developing its gardens to their utmost limits and at the same time making vast contributions to the progress of knowledge It has done more it has blended a double function which might have split the Society to its roots into a harmonious whole so that the Zoo has become the patron of science contributing handsomely to its coffers and science the handmaiden of the Zoo has eased the conditions of its inmates and furthered their welfare in the details which make life in captivity worth living

In his Centenary History Sir Peter Chalmers Mitchell traces with easy knowledge the multifarious lines of activity which have coalesced to make the Zoological Society and its Zoo what they have become The Society owes its origin in 1826 to Sir Stamford Raffles who lived just long enough to see it well on its way to success Its earliest stages were recently discussed in an article in NATURE (May 4 p 687) so that no further reference to its foundation need be made except that it is desirable to point out that following Scherren s The Zoological Society of London (1905) undue weight was there placed upon the part taken by the Zoological Club of the Linnean Society Chalmers Mitchell has investigated this and many other controversial points with minutest care and the pains which he has evidently bestowed upon the consultation of original sources of information ensure that his is the last word in these matters

Since the Zoo is the hub of the system let us glance at the major developments which have kept it in the centre of public favour The chart which forms a frontispiece to the volume and in itself is a mine of information shows plainly that an unprogressive policy is reflected in stationary or dwindling audiences The fresh appeal of the original gardens soon wrought itself out and was followed by a steady decline in numbers of fellows in numbers of visitors and in income which must have caused deep concern to those in authority Now a glance at the series of plans of the gardens at different stages of development appended to the volume shows that since the first concession of twenty acres in 1826 there has been a gradual extension of area to more than double the original size But the chart reveals no connexion between increasing prosperity and mere accretion of acres On the other hand it clearly demonstrates that the secret of success from the public point of view is the staging of special features which not only attract a temporary fresh influx of visitors but tend to raise subsequent attendances to a new base level

Accidental influences such as the Great Exhibition of 1851 or the International Exhibition of 1862 are naturally enough reflected in the numbers of visitors to the Gardens but the lesson of the chart is that special efforts at display meet a rich reward Royal collections of animals since that first exhibited by the Prince of Wales in 1876 have always been exceedingly popular but the organised works which have brought overwhelming success are the Mappin Terraces in 1913 the Aquarium in 1924 the Reptile House in 1927 and the Bird House in 1928 Taking the appointment of the present secretary in 1903 as a convenient datum line it is a remarkable testimony to his progressive policy that in the quarter of a century which has since elapsed the number of fellows has more than doubled annual income has trebled and the number of annual visitors has increased almost fivefold

Keeping step with these popular developments have been no less important changes which appeal perhaps more strongly to the scientific observer notably the vital innovation from the stuffiness of closed and warmed cages to natural temperatures and open air the introduction on a large scale of radiant heat for the animals and a great step in progress the acquisition of Whipsnade Park and the planning there of scenic panoramas and paddocks on the most advanced lines

Of the purely scientific activities of the Society we have left ourselves no space for comment The *Proceedings* and *Transactions* which are stocked with results based largely upon the collections themselves are as indispensable to the scientific worker as is the Zoological Record and the one time museum notable for the large proportion of type and historic specimens which it contained on its dispersal enriched the Natural History Museum at South Kensington and to a lesser extent other institutions

The century not without its dissensions and difficulties has been one on which the Zoological Society and the nation can look back with pride and from which they can look forward with confidence in a strong guidance enlightened by scientific knowledge and enriched by the naturalists wide sympathy with living things J R

Alpine Tectonics

The Nappe Theory in the Alps (Alpine Tectonics, 1905–1928) By Prof Dr Franz Heritsch Translated by Prof P G H Boswell (Methuen's Geological Series) Pp xxx + 228 + 8 plates (London Methuen and Co , Ltd , 1929) 14s net

THE existence of great overthrusts in the Alps was recognised by Escher von der Linth in 1853, and by von Richthofen in 1859, and was proved from the mining at Idria by Lipold in 1874 , but it was only after the work of Schardt in 1894 that these displacements were generally accepted and explained as nappes Nappe is the French word for a sheet, but the term is used in Alpine geology, as in the title of this book, as an abbreviation for a *pli nappe* or *nappe de recouvrement*, or over folded sheet Such nappes are explained as due to flat lying folds from which, as they are pushed forward, the central limb is ground to powder and worn away According to the advocates of the theory, the nappes in the Alps cause horizontal displacements that are well established for 60 miles, while the total movement may be much greater , for some of the mountains seen from the terrace at Berne are regarded as parts of Africa pushed into central Switzerland

The difficulty of the subject to British students is increased by its scattered literature and special technical terminology The book by Prof Heritsch of Graz, therefore, should prove of great service, as a guide to the modern literature on the Alps, especially on the Eastern Alps, and as a statement of the evidence for and against the nappe theory The work has been extended and revised by help of the author during the translation, which in several respects is an improvement on the original It has additional illustrations, and the excellent glossary which has been prepared by the translator will, it may be hoped, standardise the English equivalents of many of the tectonic terms

The attractiveness of the nappe theory depended upon its seductive simplicity The alternative explanations are often complex When, however, the theory is followed into details, the simplicity disappears owing to rapid changes in the hypothesis, extreme differences of opinion among its supporters, its evasiveness of crucial tests, and fantastic explanations introduced to explain special cases The theory is often dependent upon uncertain identifications of the age of the rocks For example, the Matterhorn consists of a pyramid of gneiss resting on schists which are regarded as altered Trias If this age of the basal schists is incorrect, the upper part of the Matterhorn need not be explained as a far travelled erratic Similarly with the Hohe Tauern in the Eastern Alps the nappe theory there depends on the identification of part of the schists as Trias, but if they are pre Cambrian the application of the theory to the Tauern is invalid

The difficulties of rock identification are met by the assumption that the differences between various parts of the same sheet are due to differences of facies For example, the rocks identified as the southern root of the Silvretta nappe form the hills east of the northern end of Lake Como These rocks are so different from those of the Silvretta as to suggest doubt as to their belonging to one sheet This difficulty is circumvented by the assumption that the differences are due to the rocks having been deposited so far apart that they occur in different facies This facies argument, as remarked by Prof Boswell in the preface, is naturally regarded with suspicion by British geologists, who are used to the rapid lithological changes among our Jurassic deposits The extreme movements claimed have not been supported by the discovery in the Alps of the characteristic North African facies of the Eocene or Cretaceous

The nappe theory is faced by serious physiographic difficulties According to some estimates, the nappe movements in the Miocene and Pliocene must have piled up rocks to a thickness of about 20 miles above the Alps All this material must have been since removed by denudation, and there is no trace of the debris on an adequate scale in the surrounding areas Another physiographic difficulty, to which attention was directed by Prof Bailey Willis in 1912, is that there are in the Alps old land surfaces that date from the Lower Miocene and even earlier, and their existence, Prof Heritsch remarks, is quite irreconcilable with the supposed later nappe movements Such difficulties have been often ignored by the supporters of the nappes, who, in their enthusiasm, regard the evidence in favour of the theory as so convincing that they are confident that explanations of these difficulties will appear

The special merit of Prof Heritsch's book is that it states the issues impartially, and by directing attention to the difficulties and uncertainties in the nappe theory, should guide the discussion to the critical points, and thus help in the solution of the problem The book is not easy reading, owing to its conciseness and brief statement of views of bewildering variety It should, however, prove indispensable to students of mountain structure as a guide to current Alpine literature and opinion

An Introduction to the Study of Ore Deposits By Dr F H Hatch Pp 117 (London George Allen and Unwin, Ltd , 1929) 7*s* 6*d* net

MOST books devoted to the study of ore deposits suffer from an attempt to give too much detail It is manifestly impossible to write an account of the mining fields of the world in small compass and Dr Hatch has not attempted this He has set himself the ideal of producing a real introduction to the subject elucidating everywhere the general principles by illustrations taken from actual instances, and it must be said that in this he has been extremely successful Many of the examples are naturally chosen from his own experiences in different parts of the world, and the outcome is an admirable instance of the application of scientific ideas to a truly practical subject

The first chapter is an interesting historical summary of theories of ore genesis, largely based on the author s presidential address to the Institution of Mining and Metallurgy in 1912, but brought well up to date The next nine chapters are concerned with the different processes of ore formation and alteration the last named being of course a matter of the greatest practical import, in such matters as zones of oxidation and of secondary enrichment Chap ix deals with the origin of residual deposits of all kinds including the laterite bauxite group and manganese deposits, as well as residual ore bearing gravels It is pointed out that in the tropics so called alluvial propositions are often in reality rock in place, so deeply decomposed as to be workable by hydraulic methods The last chapter deals with the forms of ore bodies, and there are no less than four indexes, of authors, localities minerals, and a general index of subjects

This book may be strongly recommended as being what it was intended to be—a real and valuable introduction to the study of mining geology R H R

Denkschriften der Schweizerischen Naturforschenden Gesellschaft (*Mémoires de la Société Helvétique des Sciences Naturelles*) Band 64, Abh 2 *Nouveau catalogue des moules d'échinides fossiles du Musée d'Histoire naturelle de Neuchâtel* Exécuté sous la direction de L Agassiz et E Desor par J Lambert et A Jeannet Pp ii + 83 233 + 2 planches (Zürich Gebrüder Fretz A -G , 1928)

ABOUT 1838, Louis Agassiz had assembled in Neuchâtel specimens of fossil sea urchins borrowed from various public and private collections to aid him in his Monographies d'échinodermes" Many of these specimens became the types of his new species , all were authenticated , and he conceived the happy idea of making plaster moulds from them and of distributing the casts to museums or students interested in the subject After Agassiz left Neuchâtel, the good work was continued by E Desor and later by H Michelin, down to about 1858, when the number of species thus represented amounted to 960 A second edition of the casts was begun in 1854 by L Coulon, who had succeeded to the direction of the Neuchâtel Museum It is to be feared that after a time in many museums these valuable documents of research, having become dusty, lost the respect of a new generation of curators and were not kept in order Even at Neuchâtel itself, the present director 'found the casts piled up at random in two large boxes and sometimes spoiled "

Such being the state of things all serious students of the Echinoidea should be most grateful to Messrs J Lambert and A Jeannet for an extremely careful inquiry into the history of the series, the provenance and ultimate location of the originals the distribution and fate of the casts, and above all for the annotated list of the species represented In this list each entry gives the name under which the cast was issued the subsequent nomenclature of the species, the horizon and locality of the original, with references to descriptions and figures of the specimen In short, nothing seems missing from this *apparatus criticus* F A B

Three Lectures on Neurobiotaxis and other Subjects, delivered at the University of Copenhagen By C U Ariëns Kappers Pp 76 (London William Heinemann (Medical Books), Ltd , 1928) 7*s* 6*d* net

THE Lancashire Asylums Board was recently assured by its officers that persons equipped for neurological research would not now be forthcoming in England, even were money available to employ them If this extravagant statement must be set aside as merely an item in official conversations , it is unfortunately true that Great Britain has now fallen far behind its continental neighbours and America in this direction It is therefore to be hoped that these lectures will have a wide circulation among British readers, in whom neurological interest may thereby be reawakened

The theory which Dr Ariëns Kappers develops in the first of the lectures was first advanced by him more than twenty years ago, and has suffered misunderstanding in Great Britain owing to confusion with the chemotaxic explanation of nerve development proposed by Ramón y Cajal Thus, even so acute a critic as Elliot Smith has put forward Kappers's own principle—one of relative growth at critical moments of development—while implicitly rejecting the theory as unnecessary (Cunningham's " Textbook of Anatomy ")

The present lucid treatment lays stress on simultaneity of function as the essential principle underlying anatomical correlations in the nervous system, and extends the theory to cover a variety of freshly observed instances, particularly some of the baffling phenomena of the decussation of fibre-tracts It is possible to appreciate the far-reaching and illuminating character of the principle of neurobiotaxis without, however, endowing it with causal significance as Dr Ariëns Kappers does on p 36 The last of the three lectures is a brilliant account of the development of the cerebral cortex in terms of neurobiotaxis

Solutions and Heat Engines

MAY I add a word to the discussion on osmotics ? As regards the osmotic pressures of mixed gases I would point out that the reviewer s case (2) (NATURE, April 13, p 569), where two atmospheres of nitrogen are inside the chamber and one atmosphere of hydrogen is on each side, is not in osmotic equilibrium if there be any interaction between the molecules of nitrogen and hydrogen the equilibrium will obtain, so it seems to me only when the partial pressure of the hydrogen equals its pressure outside, and we have, as yet, no means of calculating this effect

With liquid solutions a little consideration will convince one that there are a multitude of formulæ, functions of the concentration, which will fit the facts for dilute solutions Among these may I direct attention to one which seems promising ?

If the observations of Berkeley, Hartley, and Burton (*Phil Trans R S*, vol 218) on the osmotic pressures of cane sugar and α methyl glucoside are tabulated, as below, against the weight concentration multiplied by the density of the solution, squared, the figures agree to about 5 per cent

NOTES —c_2 and c_1 are the concentrations *i e* number of grams per gram of solution *d* is the density of the solution compressed to its osmotic pressure

It is easy to see that the osmotic pressures must be a function of the density, for consider two cylinders containing different solutions and furnished at the bottom with semi permeable membranes which just touch the surface of the solvent If we neglect the stratification caused by the gravitational field, then, when there is equilibrium across the membrane, $P = hd$ where P is the osmotic pressure, d the density of the solution, and h its height, hence

$$\frac{P_1}{P_2} = \frac{h_1 d_1}{h_2 d_2}$$

An explanation of the weight concentration part of the formula can be put forward. Assume that the solute takes no part in the bombardment of the membrane, that is, this bombardment is conditioned only by the solvent molecules It will be necessary, therefore, to put a pressure on the solution to increase the speed of the solvent molecules such that the number striking the membrane per second on the solution side will be equal to the number on the pure solvent side It is easy to see, if our solution is an ideal one (that is, there is no interaction between the two sets of molecules and therefore there is no change in volume when the *liquid* substances are mixed) that this pressure will be proportional to c_2 and if we remember we are dealing with a *defect* in bombardment, it will roughly be inversely proportional to c_1 The *c* s are the number of grams of solute (c_2) and solvent (c_1) in one gram of solution—and c_2/c_1 = weight concentration/100

Obviously this explanation is but a rough approximation to actual conditions, but if the formula applies to substances other than the sugar type of molecule, we have a rule of thumb means of calculating both osmotic pressures—a matter of some importance as they are just as much physical constants as the density or refractive index

A little thought will make it evident, if we remember that we are still considering an ideal solution, that we could have put $c_2/c_1 = v_2/v_1$ (where v_2 and v_1 are the volumes of the respective components in 1 c c of solution), and we should have had a more consistent formula But with the *v* s[1] of the actual solutions the results are not so good—they only agree to 15 per cent, this is not to be wondered at, for we have not taken into consideration the molecular interaction nor the effect due to closeness of packing I think, however, that these two considerations can be allowed for if we may assume that when one molecule strikes another the rebound is not instantaneous and a 'rest period' ensues the effect of closeness of packing may turn out to be a function of the density, but I have not the means at hand for calculating this I hope to return to the matter in another communication

BERKELEY

[1] These are derived from Porter's (*Proc Roy Soc*, 1908, p 480) definition of his s_1 and s_2

Determination of Crystal Potentials by Diffraction of High Voltage Electrons

WHEN electrons are diffracted by a crystal cleavage face, Bragg's law, on taking account of the refractive index of the crystal for the electron waves, becomes $n\lambda = 2d \sin\theta\sqrt{1 + \frac{\mu^2 - 1}{\sin^2\theta}}$, or, putting $\mu = \sqrt{1 + \frac{\phi}{V}}$ and $\lambda = \frac{h}{mv} = \sqrt{\frac{150}{V}}$ A, where ϕ is the inner potential of the crystal and V is the energy of the electrons in volts, we obtain

$$\sqrt{V}\sin\theta = \frac{n\sqrt{150}}{2d}\sqrt{1 - \frac{4d^2\phi}{150n^2}} \qquad (1)$$

For a spacing 4 A the first order will thus disappear entirely for ϕ as small as 2 4 volts, whatever the value of V This wide variation from Bragg's simple law, then, will be quite as marked for high as for low voltages, and since swift electrons are less liable to be deviated by stray fields, etc, the high voltage method ought to be the more suitable for determining ϕ The surprisingly large effect of refractive index at these high voltages depends on the very small angles of refraction which occur, and is only strongly marked when the reflecting plane is the free surface of the crystal This effect has been pointed out by Prof G P Thomson (*Phil Mag*, 6, p 939, 1928)

Strong spots were obtained on a photographic plate by diffraction from the cleavage faces of calcite (1, 0, 0), galena (1, 0, 0), and antimony (1, 1, 1) For each spot the product $\sqrt{V} \sin \theta$ was constant within the limits of experimental error for the range 10 to 45 kv, but spacings calculated for $\phi = 0$ differed widely from X ray determinations

In the case of calcite there were two spots on the equator line Photographs were taken of each, a willemite screen being used in setting the crystal at the correct angle Substituting the values of $\sqrt{V} \sin \theta$ in equation (1) and taking the spots to be the nth and $(n+1)$th orders, we get two equations to determine n and ϕ These give $n - 3$ and $\phi = 22$ volts, and for this value of ϕ the first and second orders disappear

Galena gave one spot on the equator and two other spots vertically above and below it, that is, parallel to the axis of rotation, which was a cube edge The latter spots were too near the equator line to be due to reflection from any of the geometrically possible planes of the crystal if refraction took place at the (1, 0, 0) plane Good agreement was obtained however, by supposing the crystal surface to be rough and refraction to take place at the plane producing reflection This being the case, the spot on the equator line had to be taken as (6, 0, 0) and the spots above and below it as (6, 0, 2) with ϕ equal to 18 2 volts The plates also showed faint vertical lines at positions corresponding to (8, 0, 0) and (10, 0, 0) for the above value of ϕ The accompanying reproduction (Fig 1) is a galena photograph showing the equatorial spot and the fainter spots vertically above and below it The part of a circle on the extreme right is where the scattered electrons are cut off by the camera

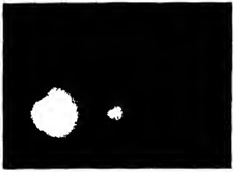

Fig 1

The pattern from antimony was similar to that of galena but less well marked, the spots above and below the equatorial spot being too faint to measure For the spot on the equator line n was so chosen that the corresponding value of ϕ made the $(n-1)$th order disappear, whence $n = 4$, $\phi = 25$ volts

In the calcite photographs, but not in those of antimony and galena, in addition to the spots there were a number of crossing lines, which were obviously similar to those obtained by Kikuchi (*Proc Imp Acad Jap*, **4**, p 475, 1928)

No great accuracy is claimed for the above results, the experiments being of a preliminary nature, but the rapid variation of $\sqrt{V} \sin \theta$ with ϕ indicates that the method may be of importance for precise measurements of the inner potential of crystals

Luminous Discharge in Gases at Low Pressures

If the Lecher circuit previously employed for generating a luminous discharge in electrodeless tubes by electric oscillations of high frequency—20,000 kilocycles or more—(Nature, **123**, p 346, 1929), is exchanged for short coils, the luminosity can be much increased By the same means it is possible to make the discharge pass through narrow quartz capillaries less than a millimetre in width, thus realising a source of light which has the linear shape suitable for spectrography, and moreover requires a very minute quantity of the gas to be examined

With a plate current of, say, 50 milliamperes at an anode potential of 1000 volts, the light emitted from nitrogen or from the oxides of carbon under these conditions is so intense, that an exposure of thirty minutes or even less suffices for giving with a large quartz spectrograph a fully developed band spectrum in the ultra violet With the inert gases the luminosity is very intense, especially with neon, which gas can be excited to give light of an intensity almost insupportable to the eye both in narrow capillaries and also in wider tubes introduced within the coil through which the discharge is passing Experiments which have still to be carried out will show whether krypton excited by this means in electrodeless tubes will be suitable as a source of the line at 5649 A, recently proposed for a new standard of wave length

Carbon monoxide and dioxide both show a rapid dissociation when subject to the oscillatory discharge Probably for this reason my attempts to separate their spectra by the flow method have so far failed Carbon monoxide excited when passing through a narrow capillary at a velocity of 5 metres per second gives a deposit of carbon, which in the course of a few minutes obscures the light and finally intercepts the discharge Hydrocarbons from tap grease, if once happening to be present within the tube while the discharge is passing, also give a carbon deposit, which no subsequent baking out of the tube in a high vacuum will remove, only burning out by protracted discharge with air or oxygen within the tube If the discharge is made to pass through a tube contaminated in this manner at a low pressure, the oxygen produced from the disintegration of silica is largely converted into oxides of carbon which emit the white light erroneously ascribed to ozonised oxygen in my previous communication (loc cit)

In my spectrograms from the oxides of carbon excited in this manner, all the Deslandres bands belonging to the first negative carbon spectrum falling between 2300 A and 2900 A, as measured by R C Johnson (*Proc Roy Soc*, London, A, **108**, p 343, 1925) have been identified, and an additional number of fainter bands of similar structure The double bands near 2896 A and 2883 A show conspicuous variations in intensity on different spectrograms, which lends support to the view that their origin is different from that of the other bands of the series, which have also a different structure Compare the work of Fox, Duffendack, and Baker (*Proc Nat Academy*, Washington, **13**, p 302, 1925), who have found these two double bands to be due to carbon dioxide

The red fluorescence from quartz or glass excited by the oscillation I now find to have been previously noticed by Wood and Loomis (Nature, **120**, p 510, 1927) and also by McCallum (*ibid*, **121**, p 353, 1928), whose communications had escaped my notice The view of the first named authors that this fluorescence is in some way due to excited molecules or ions of oxygen is no doubt correct, as can be beautifully demonstrated by deflecting with a strong horse-shoe

magnet the egg shaped luminosity of greenish yellow colour which is formed between the electrodes in a discharge tube of wider diameter containing pure oxygen at low pressure At the points where the de flected egg is brought near to the wall, two patches of brilliant red appear, separated by narrow, dark inter spaces from the rim of gold coloured fluorescence next to the electrodes With other gases quartz fluoresces in the deep blue or violet, sometimes in the green, whereas the red fluorescence, corresponding to a band near 620 $\mu\mu$, is only observed with oxygen at low pressure

HANS PETTERSSON

Structure of the Band Spectra of the Hydrogen and Helium Molecules

IN the spectrum of the hydrogen molecule many regularities have been found recently, especially by Richardson and his co workers In a note in the *Zs f Physik* I suggested an interpretation of those regularities based mainly on the theory of band complexes and the analogy with the helium band spectrum The analogy was incomplete in so far as the bands found in the spectrum of the hydrogen molecules are analogous to helium bands which can be predicted from theoretical considerations, but which had not been actually found I have found these missing helium bands now Their structure is exactly analogous to that of the hydrogen bands given by Richardson and Davidson (*Proc Roy Soc*, A, **123**, 54, 466, A, **124**, 50, 69), as will be best apparent from a description of their peculiarities From the red to the violet we have the following branches

Transition	Description of the Bands	Richardson's	Finkelburg and Mecke
$\sigma\Sigma \rightarrow 2\pi\Sigma$	P and R branch of about equal intensity	${}^1A \rightarrow 2^1S$	${}^3D \rightarrow 2^3S$
$\delta\Sigma \rightarrow 2\pi\Sigma$	R strong P weak	${}^1C \rightarrow 2^1S$	${}^3P_2 \rightarrow 2^3S$
$\delta\Pi_b \rightarrow 2\pi\Sigma$	Only strong Q	${}^1B \rightarrow 2^1S$	${}^3P_1 \rightarrow 2^3S$
$\delta\Pi_a \rightarrow 2\pi\Sigma$	P strong R weak	${}^1A \rightarrow 2^1S$	${}^3P_0 \rightarrow 2^3S$

In addition to these seven branches there is one more P, Q, and R branch arising from $\delta\Delta_{a\ b} \rightarrow 2\pi\Sigma$ transitions These branches are very faint, and their intensities make it probable that they are only present if the regular precession of the orbital electronic moment of momentum around the nuclear axis is considerably perturbed It is not yet quite certain to which hydrogen bands these three branches corre spond If one takes these facts together with the arguments mentioned in the note in the *Zs f Phys*, the evidence in favour of the proposed explanation of the hydrogen bands becomes very strong The properties of the helium terms are well known (see the letter to NATURE of May 11 and a fuller discussion in print in *Zs f Phys*), and therefore I think there is no reason to accept the conception of Finkelburg and Mecke (*Zs f Phys*, **54**, p 537) of the hydrogen bands which is given in the last column of the table

All the bands the analysis of which seems most certain find their explanation in this way The in terpretation of some of the remaining terms does not seem to be easy There are reasons, however, which make it not improbable that the assignment of initial vibrational and electronic quantum numbers ought to be changed for some bands In such cases Richard son and Davidson's and Finkelburg and Mecke's analyses usually do not agree with each other

A few words may be added about the newly dis covered helium bands There are three groups of them, all belonging to the triplet system, one in the red (4σ and $4\delta \rightarrow 2\pi\Sigma$), one near 535 $m\mu$, and one near 495 $m\mu$ (5σ and 5δ resp 6σ and $6\delta \rightarrow 2\pi\Sigma$) The group near 535 was first found by Merton and Pilley It and the 495 group have been partly analysed by Fujioka (*Zs f Phys*, **52**, p 657) All the bands are degraded toward the violet The initial terms were known from other bands, the new final term $2\pi\Sigma$ lies 6118 4 cm^{-1} *above* the corresponding $2\pi\Pi$ ($2p$) term, whereas in hydrogen the $2\pi\Sigma$ level (B level) lies 8892 cm^{-1} *below* the $2\pi\Pi$ (C) level This is the most remarkable difference between the hydrogen and the helium terms, whereas in most other respects they are exactly analogous That will be seen more clearly from the detailed paper The new helium bands will be described in collaboration with Messrs Takamine and Imanishi Their dis covery also made possible the hitherto doubtful ana lysis of bands in the region around 400 $m\mu$ and 378 $m\mu$ It appears that perturbations of the kind described in my letter to NATURE of Mar 23 occur for the $\sigma\Sigma$ (s) and $\delta\Sigma$ (z) terms The perturbation moves to low or j if we go to the higher terms $4z$ (17), $5z$ (9), and $6z$ (5) are the perturbed z terms

The Primary Process in the Formation of the Latent Photographic Image

I HAVE read with much interest the communication from Dr F C Toy and Mr G B Harrison in NATURE of May 4, 1929, p 679 The experiments described on the photo conductance phenomenon in silver bromide afford valuable confirmation of the results obtained by Dr W Vanselow and myself on the photo voltaic effect at silver bromide silver elec trodes, which were briefly described in the sixth Hurter and Driffield Memorial Lecture[1] These results, we consider, not only demonstrated the primary separation of electrons by light in the photo lysis of silver bromide, but also gave the first evidence that this separation of electrons is actually related to the liberation of bromine The negative potential difference ascribed to electron liberation is produced within $\frac{1}{250}$ second of the incidence of the light, attaining a maximum within $\frac{1}{50}$ to $\frac{1}{25}$ second

We regard these, and other results now being published in the *Journal of Physical Chemistry*, as confirming the hypothesis of electron liberation from the bromide ion and transfer to the silver ion, which was proposed by Sheppard and Trivelli and inde pendently by Fajans, in 1921 Dr Toy and Mr Harrison interpret their recent results in terms of this same theory Now it may be noted that the photo-conductance phenomenon by itself only shows the production of mobile electrons, but not that they are *valence* electrons from the bromide ions The corre-spondence of the primary photo conductance current with the photographic effect, as demonstrated for wave length sensitivity and time order sensitivity by Dr Toy and his collaborators, is unquestionably very significant Considered in relation with our measure ments of the photo voltaic effect, they strongly sup-port the view that the inner photo electric effects—photo voltaic and photo conductance—as also the photographic and photochemical effects, all derive from the same primary separation of the electron from the bromide ion

In terming this the primary event, I take leave to differ somewhat from Dr Toy and Mr Harrison in regard to their statement on latent image formation

[1] The Formation of the Photographic Latent Image, *Phot J*, **67**, 397 414, 1928

They say "The complete building up of the latent image is now generally considered as divisible into two stages (1) The absorption of light by silver bromide and the immediate resulting mechanism, and (2) complicated chemical reactions between the product of the light action and the other substances, such as gelatin, present in the emulsion" This description seems to me incomplete, because it applies equally to the formation of the visible image It seems to me preferable to say that the primary event or elementary process is the separation of the electron from the bromide ion We have then

$$\bar{\mathrm{Br}} + h\nu \longrightarrow \mathrm{Br} + \theta$$

followed by other processes

$$\overset{+}{\mathrm{Ag}} + \theta \longrightarrow \mathrm{Ag(atom)}$$
$$\mathrm{Br} + \mathrm{Br} \longrightarrow \mathrm{Br_2}$$
$$\mathrm{Br} + \mathrm{Acceptor} \longrightarrow \mathrm{(A)Br}$$
$$\mathrm{Br_2} + \mathrm{Acceptor} \longrightarrow \mathrm{(A')Br_2} \text{ or } \mathrm{(A')Br} + \mathrm{HBr}$$

The formation of a latent image involves both the segregation of bromine *and* the aggregation of the silver atoms produced The mode of this 'aggregation' appears to me an essential aspect of the "complete building up of the latent image"

This formulation of the steps tacitly assumes that no work of predissociation or disgregation of the silver halide lattice is necessary at the interface with a conductor, as suggested in my letter in NATURE (121, 574, 1928) and discussed in detail in the *Journal of Physical Chemistry* (33, 250, 1929)

The Classification of Soils for Purposes of Survey

THE growth of interest in soil surveys of recent years and the impetus given to the natural study of soil by the work of the Russian pedologists have led to considerable discussion directed towards the formulation of a world system of classification C F Marbut (*Proc Intern Congr Soil Sci*, iv 1, 1928) has proposed a scheme which amplifies the earlier classification of Glinka, using profile as affected by climate as a basis The problem of the worker in a small area will generally be the final subdivision of an area of soils mainly belonging to a single group in the world scheme

The accompanying scheme indicates an attempt to classify Welsh soils, which belong to the feebly podsolised group, for the purpose of soil survey The first division is into suites each characterised by the same or similar parent material and is, in a qualified sense, geological The next division is into phases according to conditions of formation This furnishes the series which, following American practice, are named after the localities in which they have been studied The final types are given by considerations of texture

Parent Material	Free Drainage			Impeded Drainage.	Alluvium
	Normal Phase	Drift Phase	Podsol Phase		
Igneous rocks, Pyroclastic rocks, Cambrian and Ordovician grits	Bangor	Ebenezer	Ogwen	?	?
Mona Complex	Anglesey	Gaerwen	Holyhead	Gesail	Braint
Palaeozoic sediments, except Cambrian Grits	Powys	Penrhyn	Hiraethog	Bethel	Conway
Old Red Sandstone	Monmouth	?	?	?	?
Carboniferous Limestone	Gower	Pentraeth	?	?	Talwrn
Non-calcareous Carboniferous sediments	Neath	Merton	Ruabon	?	?
Trias	Salop	Wrexham	?	?	?
Rhaetic and Lower Lias	Glamorgan	?	?	?	?

For example, soils derived from non-calcareous sediments of Cambrian, Ordovician, and Silurian age, excepting hard crystalline grits, form one suite Normal sedentary soils of this suite are called the Powys series and give such types as the Powys silt loam, Powys light loam, etc The corresponding drift soils form the Penrhyn series, soil with impeded drainage, the Bethel series, podsolised soils, the Hiraethog series, and alluvial soils, the Conway series

In addition there are a few series depending on purely local conditions of surface geology, and topographical soils, such as marine alluvium, dune, fen peat, mountain peat, and heath peat, for which it is proposed to use a descriptive rather than a local nomenclature

The Origin of Adaptations

IN NATURE of June 1 there is printed the report of a lecture by my old friend, Dr E J Allen, on "The Origin of Adaptations" I do not desire to enter into a detailed criticism of the views put forward in that lecture, but in one paragraph Dr Allen refers to my views He correctly states that I believe that definite proof of the inheritance of acquired characters is available in the works of Kammerer, Durkhen, and Brecher, but that Graham Kerr and Goodrich have put forward strong arguments on the other side So far as I understand the attitude of Graham Kerr and Goodrich, it amounts to this that having convinced themselves on *a priori* grounds that the inheritance of acquired characters is impossible, they refuse to credit any evidence on the other side Such an attitude is very illuminating as to the mental outlook of these two biologists, but it is not helpful in throwing any light on the question

The question of the reliability of Kammerer's results has been placed in an entirely new light by the visit of Prof Przibram, who was Kammerer's teacher, to London. Przibram saw Kammerer's experiments performed, and in particular saw the critical specimen of *Alytes* living the sole question for him was who, during Kammerer's absence on war service, interfered with this and other specimens. He had no doubt whatever as to the *bona fide* of the experiments, for they were performed under his immediate supervision.

As to Durkhen's work on the colours of the pupae

of white butterflies, Przibram agreed with me that the experiment and the results obtained were a repetition and confirmation of Kammerer's work on *Salamandra maculosa* I think that I was the first in Great Britain to direct attention to the critical and important character of Durkhen's work and I suggested to my friend Dr Heslop Harrison, who had so much skill in breeding insects, that he should endeavour to repeat the experiment This he successfully accomplished, and this feat makes the dogmatic criticism of Kammerer's work look rather foolish

Since that time Metalnikoff, of the Pasteur Institute in Paris, has proved the inheritability of acquired immunity in the caterpillars of the beeswax moth, and this experiment is doubly interesting, because the effect on the offspring of the acquired character only became obvious after five generations, incidentally confirming Lamarck's view who rightly emphasised the importance of the time factor in use inheritance

Dr Allen quotes with approval Hertwig's statement that the real question is not "Are modifications inherited?" but How are now factors acquired?" In this statement there lurks an obvious fallacy, which one might expect from Hertwig, but not from Dr Allen There are no 'new factors' in animals Every apparently new factor turns out on close analysis to be an enhancement or a diminution of a pre existing one and the supposed difficulty of explaining the value and function of incipient characters can only be characterised as a Darwinian nightmare

Cosmic Radiations and Evolution

THERE seem to be no sure grounds for believing that the penetrating radiations are uniformly distributed throughout space If they are not, and if considerable variations in the strength of those reaching the earth have occurred in the past—possibly referable to translatory movements of the solar system—then serious effects upon organic evolution may have taken place Millikan estimates their present energy as equal to about one tenth of that reaching the earth from the luminous radiation of the stars At present, therefore, the penetrating rays are probably without positive effects upon organic life It does not follow, however, that a recent decline in strength would be without serious effects

The influence of gamma radiations upon organic structures has been studied from many points of view It would seem to resolve itself finally into one of ionisation, the gamma radiations when absorbed being transmuted into beta rays Medical researches directed to the elucidation of the changes consequent upon radiations applied to healthy and to morbid tissues appear to lead to the conclusion that a selective influence is involved, the morbid tissues being destroyed by the same radiations as fail to affect the neighbouring healthy tissues, but which seem, rather, to stimulate the latter to an attitude of increased stability

This at once suggests an issue of rather sensational kind, and certainly at present purely speculative I refer to the present world wide increase of cancer in its various forms This increase might be explained as due to the disappearance in recent times of a controlling factor which, in a word, acted in the same manner as γ rays or X rays upon animal tissues

J JOLY

Trinity College, Dublin,
May 26

DR JOLY has pointed out the possibility that cosmic radiations, acting as a purely environmental factor, have produced changes in the resistance of human cells to the attacks of cancer

In this connexion the work of Goodspeed and Olson (*National Acad of Sciences*, vol 14, No 1, Jan 1928) is of particular interest These investigators have shown that a high percentage of variation in the progeny may be produced by the radiation of the sexual cells of the parents with X rays In one population of 200 plants from radiated parents there were more than 70 per cent of variant individuals Visible alterations in the chromosomes accompanied these morphological variations The results were obtained with rather intense radiation acting for a short time

From these observations it appears possible that cosmic radiations (which are of the nature of X rays) have been a factor in the production of variations by direct action on the germplasm

Electrified Omnibuses

IT may be worth while to record in NATURE an observation made by me of electrification of an omnibus Recently I was going to board an omnibus in Victoria Street and in order to do so grabbed the brass rail just as the omnibus was about to stop In doing so I received an unmistakable electric discharge On coming back after a short time I went to the same spot—opposite to the Army and Navy Stores—and put my knuckle against the rails of those omnibuses which I could touch before anyone else did so In all cases in which they came along at a brisk pace and pulled up quickly I received a sharp prick from the spark In one case a second application was rewarded by a second spark It was at a time when the sun was shining down the street and all was as hot and dry as could well be No doubt it was the scuffling of the rubber tires on the polished asphalt that gave rise to the electrification In intensity the shock, if such a term can be used, was two or three times as strong as that obtained after stroking a cat by the fire on a frosty night when a visible spark may be obtained from the cat's nose

In all my experience of omnibuses this is the first time I have noticed this electrified condition, and I have never heard of it from anyone else

Spectrum of Trebly Ionised Bromine.

I REPORTED classification of the spectrum of doubly ionised bromine in a previous note to NATURE of Feb 16, p 244 Following that work, I have been able to classify the lines of trebly ionised bromine The chief lines of the group $N_3(O_1 \leftarrow O_2)$ have been thus located ${}^3P_2\,{}^3D_3$ line at $\nu = 36675\ 2$, the ${}^3P_2\,{}^3P_2$ at $\nu = 40130\ 8$, and ${}^3P_2\,{}^3S_1$ line at $\nu = 42247$ The singlet system and inter-combinations have also been obtained, namely, ${}^1P_1\,{}^1P_1$ at $\nu = 42177$ The differences are ${}^3P_0 - {}^3P_1 = 506$, ${}^3P_2 - {}^1P_1 = 933$, and ${}^3P_0 - {}^1P_1 = 2532$

The Origin of Variations

By Sir OLIVER LODGE, F R S

ARTICLES in NATURE have the advantage that they are addressed not merely to experts in the same line of work as their writer—these have to be placated rather than informed—nor are they specially addressed to the school educated general public, who are more likely to recognise the etymological character of the terms used than to appreciate their physical or biological significance Articles in these pages are, I suppose, primarily intended to reach workers in other branches of science, thereby putting them into touch with modes of thought differing from but akin to their own Our relations with each other are somewhat like those of politicians in alien countries the problems are different, the methods dissimilar, but the general aims are alike

International exchange of views is sometimes valuable, international conversation at Geneva has become possible and long may it be before NATURE is subdivided into delimited areas labelled A and B Seldom, however, does a member of one group feel entitled to intervene or say a word concerning the business of any other group If he does, he runs the risk of being regarded as a trespasser and treated with contumely That of itself would matter little What usually deters him is the doubt whether anything he has to say is likely to be of the smallest use he might be merely airing his own ignorance Well aware of that likelihood, he may nevertheless occasionally venture to intervene, with all due diffidence and dependence on the charity and better understanding of those whose knowledge is so thorough that they can afford to pardon crudenesses of expression, and be willing to give favourable interpretation to presentations from another point of view

These remarks are introductory to some comments on this year's Joseph Hooker Lecture before the Linnean Society, by Dr E J Allen, on " The Origin of Adaptations ", as partially reported in NATURE for June 1, page 841, and without further apology I would thank him for this concise summary of opinions on so interesting a subject—first explicitly treated, so far as I know, by Bateson many years ago

Take then the question of heredity, on which so much turns Certain truisms may safely be laid down The only material transmitted to descendants is the germ-plasm (using that term comprehensively as including germ and sperm) No portion of the soma is transmitted, and therefore changes in the soma can only be inherited if they are such as to modify the germ plasm We know, however, that that substance is modifiable by slight changes in the environment, and hence it would appear quite possible for body changes to have their due effect Such change may be imperceptible, except when tested by the actuality of inheritance, they might otherwise escape observation hence only experience can tell us what is heritable The body is the organ which gains experience of surrounding conditions and adapts itself to them, whether it can transmit any part of such adaptation to the germ plasm can only be effectively tested by observation of the descendants If no such transmission occurs it is difficult to see how racial experience can contribute to progress I gather that observation shows that evolution proceeds in such a way that descendants are on the whole better adapted to their surroundings than their ancestors, and further, that improvements do not proceed as if executed in accordance with some preconceived set plan, but that they are flexible and able gradually to follow unexpected changes in the environment which could not have been foreseen Inheritance of modifications may be slow, but changes or adaptations of an individual may be quick, as when a flat fish rapidly and surprisingly adapts its coloration to suit the background on which it is placed In other words, adaptability of a somatic kind exists in the individual as a fact of observation, so that there is no question about the possibility of individuals adapting themselves to circumstances The question is how more serious adaptation, to permanently changed surroundings, can be conveyed to descendants

The first *vera causa* suggested is natural selection and survival value Permanent modification may result from the improved chances of life for those individuals who happen to be born with some approach to the favourable variation or mutation, subject to the added proviso that such innate peculiarity is transmissible by inheritance This doctrine, though apparently true so far as it goes, obviously does not explain how the variation arises it only acts as a lock to secure its continuance in the race when it has arrived The problem of the origin of the variation is deeper than that The survival of the fittest or the elimination of the unfit, alone, is little more than a shipwreck experience

I will now make a quotation or two from the article referred to, and as it is so accessible, and this is not a controversial epistle, I will not hesitate to introduce into my quotations words in square brackets that are not in the original In the second column of page 843, I read

> " That evolution proceeds according to laws of the same character as other [known] laws of Nature, is the common basis of all modern evolutionary theory, and was held perhaps more strongly by Darwin, Huxley, and Weismann than it is by some writers of to day "

The word " known " which I have thus introduced is surely important, for if it be omitted I do not see how anyone could doubt the statement Every event must happen in accordance with laws of Nature in the widest sense But as to whether at any given period those laws are all known, or rather whether the laws known to a particular generation are sufficient as a basis from which to explain every recognised phenomenon, may very well be doubted That, I presume, is the only point on which modern

writers can differ from what may be called the Huxley point of view—or, to make it impersonal, say, from the view that the fundamental knowledge of Nature already acquired by humanity is sufficient to account for all observed phenomena Those phenomena have been added to since the middle of last century, and everyone who knows anything of Darwin and his great protagonist must realise how eagerly the newer experimental results would have been assimilated and utilised by them

GUIDANCE AND CONTROL

The question which still remains open, as worded by Dr Allen, is ' *how* the soma influences the factors in the germ cell " Well, that is one way of putting it, from the material point of view and an interchange or circulation of hormones has been suggested as a material method For paternal inheritance this particular method may possibly lack cogency, but doubtless some machinery will be found, one can scarcely expect to see changes produced in matter without *some* appropriate mechanism ! But that alone does not solve the problem There is about the process a suggestion of purpose, as if, like all other mechanism, it were constructed for a definite object, and designed so as to work in a particular way A random circulation of hormones, or of anything else, could scarcely be trusted to effect the precise changes which, having originated in the soma and possessing survival value, ought to be transmitted to the germ plasm so that they may be inherited Hormones may, for all I know, constitute the material means of conveyance, but how do they exercise that function ? And what initiates or controls their activity ? So much is left unexplained even when the machinery is discovered

Material mechanism is just what can be followed by those whose business it is to study the physical basis of life, but mechanism is never self explanatory The most automatic mechanism ever constructed must have mind behind it, not indeed in its contemporary working, but in its design and purpose, and if the result of mechanical working simulates the effect of purpose, it may be wise to keep our minds open to the possibility that after all there may have been some purpose, or so to speak intention, in the change that is being observed and in the adaptation of the means The mechanism whereby a flat fish (to go back to that merely popular illustration) changes its pattern when greater concealment can be thus secured, has I believe been made out certain pigment cells swell, while others contract That the animal knows what it is doing is quite unlikely the mechanism presumably works automatically But surely biologists scarcely feel that they have got to the bottom of the problem when they merely point out the mechanism !

Some biologists apparently realise that a statement in terms of automatic working is not ultimately satisfying, and are said to have introduced " the idea of some psychic or psychoid influence, controlling and regulating the processes of metabolism and organic growth ", which idea is deprecated by Dr Allen, in common I suppose with many others, as too like " the animisms of primitive man ", too suggestive of conscious purpose, " such as we know only in ourselves, or by analogy assume in higher animals "

Purposive action and planning, however, do after all exist in the universe, and therefore may have to be taken into account in ways of which we at present have no suspicion It is true that the higher animals who thus act for the future have " an elaborately differentiated nervous system ", but that is only part of the mechanism for the forming and carrying out of a purpose A machine does not really explain the rationale of its own action no machine is able to do that The most elaborate machine is a mere executive

Suppose we revert to an earlier position and ask, How do we know that germ plasm may be influenced and modified or adapted to new and unexpected conditions? Doubtless we know it in several ways, but among others by the direct experiments mentioned by Dr Allen in the second column of page 842, where we are told ' that the germ plasm itself can be acted on by physical and chemical forces in the environment in such a way that mutations are produced " For

> ' Harrison has shown quite clearly that the germ plasm can be changed by chemical substances contained in the food of an animal, or in more general terms that the germ plasm can be altered by the environment "

Here, then, is a change which has been produced through proper physical and chemical means and has resulted in a mutation But surely Dr Heslop Harrison may be not impolitely called " a psychic or psychoid influence, controlling and regulating the processes of metabolism and organic growth ", and H J Muller, by finding the correct dosage of X rays for mutation production, seems to be another of those influences An imaginary observer able to watch the processes, but from whom the operator was concealed, might feel impelled to infer him But indeed we need not appeal only to recent advances The long established procedure of breeders, and even of gardeners, long ago showed that mental operations—put into effect by a nerve muscle system—were able to guide and direct the ordinary forces of Nature so as to produce variations almost at will The beneficent progress of discoveries in agriculture, from which ultimately we hope so much, is an outcome of this purposive activity of a " psychic or psychoid influence " Such an influence is therefore another *vera causa*, which may be more widely operative than at present we imagine

CONCEALED INFLUENCES

It will be said, however, it is quite unfair to bring in the operations of a highly organised product of evolution, and use that as an analogy for what occurs in connexion with low organisms without any trace of psychic or even nervous development How is it possible for anyone who wishes to adhere closely to the laws of Nature to think of any other

influences than those displayed by the organisms themselves? How can we detect concealed influences? If we attend only to matter, and to those laws which have been already ascertained, I admit it may be impossible. But a physicist is not limited to the contemplation of matter. He regards the behaviour of matter chiefly as a sign or indication of what is going on in space. Faraday showed that the phenomenon of electric charge would never be properly understood by attending to matter alone: he traced the electric field to a property of space. Charged conductors are only the boundaries or terminals of an electric field existing *in vacuo*. Similarly Poynting showed that an electric current is not propelled by anything occurring in a metallic conductor, but by an influence reaching the conductor through space. The energy of the sun reaches the earth in that sort of way. Atoms act on each other across intervening space, and it is to space that modern physics turn for explanation of cohesion, elasticity, and of what used to be called 'gravitational attraction'.

In fact, it may be said that modern physics attends very much to space and its properties, and utilises matter mainly as an index, demonstration, or manifestation of those properties. The very electrons of which matter is composed are spatial peculiarities, and seem to have more affinity with waves than our scientific ancestors suspected. An electric current, considered materially, is a procession of electrons; but the driving power is not an end thrust like that of water through a pipe: the propulsion is a lateral propulsion exerted by electromotive forces which reach the conductor through the surrounding medium, along paths which can be mapped out.

Undoubtedly we are dependent on matter for every observation; we cannot study even ether or radiation without it; occurrences in space are concealed from us, they have to be inferred. For example, a magnetic field is an etheric or space phenomenon, and yet, admittedly, it is by aid of the properties of matter that we explore and investigate such a field. But matter after all is secondary; it displays and locates the phenomenon: it helps us to deal with it and make experiments upon it; yet an actual magnetic field is turning out more like a circulation in space than anything else. Before the discovery of electric currents, the only magnets known were natural magnets and those which had been propagated from them by regulated movements. One magnet could produce any number of others, without being itself weakened, and there was no magnetism without antecedent magnetism. The parable is obvious.

The progress of science in that department, however, led on to the production of artificial magnets, electromagnets, whereby fresh magnetism could be generated by setting electricity in motion. Yet, even so, 'generated' is scarcely the correct term. The act of magnetisation seems to be only the utilisation and opening out of circuital relations which already exist, so that instead of being shut up into infinitesimal configurations they are displayed openly and made manifest. Pre-existing but imperceptible magnetism could be incarnate in matter and exhibited. All matter has close relations with the space surrounding it. Radiation is a constant means of communication, not only obviously, but also secretly, in ways only recently discovered. An atom under certain conditions can emit energy into space, and can receive energy from space; and all material activity is the result of this interchange of energy. In space, the energy is what we call potential; in matter, it is what we call kinetic. The one form is continually passing into the other, and back again.

It must be admitted that analogies prove nothing, but they are sometimes suggestive. My suggestion is that life is something which primarily exists in space, though we only know of it when it is associated with and displayed by matter. I venture to say that we shall never understand life so long as we attend to its material manifestation alone. We must always use matter as our index and means of exploration, because it is matter alone that appeals to our senses; but the reality may lie beyond or behind matter, and may only interact with it for a time. We should never have understood the laws of an electromagnetic field, and the nature of radiation, by theorising as if matter were supreme. Even now we scarcely understand the nature of gravitation, though we can apply its laws with considerable success to the motions of material bodies. Similarly, the nature of life is unknown, though a vast amount has been learnt about living bodies.

I would ask biologists to consider whether they could not, as a working hypothesis, begin to contemplate life as something existing in space as in a sort of infinite reservoir, out of which it could under appropriate stimulus enter into association with molecules of sufficient complexity to enable it to catch hold and become as it were incarnate. They might go on to suspect or infer concealed mechanism, not of a perceptible material kind, but still possibly of a physical nature, activated by something at present unknown. I suggest that concealed powers have put the organism together, in a specific form, out of such materials as came to hand. When the machine goes out of order the controlling powers cease to be able to display themselves: the instrument of manifestation is spoilt. But we need not jump to the conclusion that when they related themselves to matter they came into existence, and that when they leave matter they cease to be.

Few of the controlling powers can have attained an individual or personal existence, but we know that matter, in its more complex and higher protoplasmic forms, has been the means of individualising those concealed activities; and consequently, as developed personalities, we ourselves are able to testify and help the explorers. If they made use of all the information available they would have a wider scope for contemplating the apparently purposive movements of live things, and might realise that in studying as they do the material basis of life, they are studying the influence of some

controlling entity—perhaps etheric, perhaps psychic, probably both—by aid of the material mechanism which it utilises

CONDITIONS FOR VITALITY

There are certain narrow conditions which have to be satisfied before live things can appear—a certain narrow range of temperature, the presence of chains of carbon atoms and perhaps of oxygen and liquid water—all of which are commonly called the conditions necessary for life to exist I would rather call these the conditions necessary for vitalising or animating matter—the conditions for vitality, in other words, the conditions enabling life to enter into association with matter I admit that it is the peculiar behaviour of organised cells that we commonly designate by the term 'alive', but we must not be too much hampered by our use of terms Animated matter displays life, and the display or manifestation of life we might call vitality When vitality ceases we are apt to imagine that life has gone out of existence But we do not think that electricity has gone out of existence when a body is discharged, though it is no longer electrified, nor need we think of magnetism as going out of existence it can become concealed and go out of our ken Nor do we think of electricity as ever coming into existence—at least not under observation, it can be localised so as to display itself by material effects Animated matter behaves in a curious way, and so does electrified or magnetised matter A compass needle points north and south, as if mysteriously cognisant of those regions but everyone knows that it is only acted on by the peculiarities of the space near it

Similarly, if we try to understand apparently purposive action in animated matter, we may fail unless we realise more clearly that something is controlling and being itself displayed by that matter An electrician uses a compass needle or a filament to display or manifest an electric current, but he would not understand much about the current if he limited himself to a discussion of its material manifestation Nor do I think that we shall understand much about heredity, and the other strange occurrences dealt with by the biologist, so long as we attend only to the material vehicle or instrument of life Life enters into a nascent organism gradually, as its cellular constitution is enabled to receive it, and when, in the long course of evolution, an organism has attained sufficient complexity, the higher stages or aspects of life, called mind and consciousness, enter or are manifested too But a study of the mechanism alone will never detect more than an indication of our thoughts, plans, hopes, and aspirations, nor can we thus explain consciousness and our power of understanding what is going on in the material explored

One more quotation from Dr Allen in conclusion, with which, I need scarcely say, I heartily agree, especially if extended by the words in square brackets

"In whatever direction we look problems bristle, problems open to successful attack, and the old qualities, insight, patience, and determination, will get them solved But we must not limit the outlook, and all aspects of biological research must proceed hand in hand Botany, zoology, palæontology, the work of the systematist and of the field naturalist, the study of structure and the study of function, the work of the embryologist and of the experimental physiologist, of the geneticist and of the statistician [aye even of the physicist and the psychologist], all are necessary, and none can succeed without the others"

The Joint Meeting of the French and British Associations at Havre

IN 1914, while the British Association was meeting in Australia, the delegates of the Corresponding Societies were invited as guests at the conference of L'Association Française pour l'Avancement des Sciences, then being held at Havre Those who were present will remember the hospitable way in which they were entertained at the Hotel Frascati, at the meetings and excursions, though as day by day passed there seemed to be something mysterious going on, the hotel gradually emptied, there were signs and whisperings, the members were impressed by the enormous accumulation of foodstuffs in the warehouses, and before the meeting was closed the declaration of war explained a good deal The members had to find their way back to England as best they could, and those who had the experience will never forget it

The French Association, towards the end of July this year, again meets at Havre, and as the principal members of the British Association will then be at South Africa, our French colleagues have again extended the courtesy of inviting the other members of the British Association to attend its conference at Havre without any extra fee beyond the ordinary subscription to the British Association which would be paid in any case

In addition, the French Association has invited the delegates of the Corresponding Societies to hold their conference during the Havre meeting, and in connexion with this a sub committee was appointed consisting of the president of the Conference of Delegates, Dr F A Bather, the secretary, Dr C Tierney, and the acting secretary for the Havre meeting, Mr T Sheppard Sir Henry G Lyons was also appointed the official representative of the British Association and chairman of the organising committee referred to

At the Glasgow meeting of the British Association, Dr A Loir, whose courtesy was so much appreciated in 1914, was present and gave an official invitation to the General Committee of the British Association and was prepared to do the same for the Conference of Delegates, but apparently that body was too fully occupied to spare the necessary time Mr T Sheppard has recently visited Havre and met the chairman of the Local Committee (the English Consul, Mr H C Swan), Dr Loir, and others interested in the local arrange-

ments The Hôtel des Sociétés Savantes, next to the Lycée de Garçons, where the meetings of the French Association will be held, has been generously placed at the disposal of the British Association for any special meetings, etc These rooms provide a general meeting room for the delegates, a committee room, and an exhibition room During the conference, Dr Bather will give an address on museum matters to a section of the French Association, and Dr Pullein will speak on radiology at the request of the Association The Conference of Delegates will be held at 5 P M on July 26, when the question of the Channel Tunnel from both engineering and geological points of view will be discussed The British committee is arranging an exhibition of air photographs, regional survey maps, etc

The French Association commences its programme on Thursday, July 25, at 11 A M, when the opening session will be held at the Grand Theatre In the afternoon is the organisation of the sections, and in the evening a reception by the Corporation at the Town Hall On Friday, July 26, there will be papers and discussions, visit to exhibitions organised at the Lycée de Garçons, natural sciences by the Geological Society of Normandy and the Linnean Society of the Seine Maritime, and exhibits by the civil engineering, dentistry, meteorological sections, etc, visit to the Port and a liner, and a conference at the Grand Theatre On Saturday, July 27, there will be a visit to the English exhibitions and museum, visit to the museum at Old Honfleur, and a public conference in the Franklin Hall Sunday, July 28, will be occupied by a general excursion to Fécamp, and the unveiling of a monument to Dr Léon Dufour On Monday, July 29, further discussions, visits to various buildings, and in the afternoon an excursion to the Art Gallery and New Archæological Museum at Graville Abbey In the evening there will be a soiree at the Municipal Casino or on a liner Tuesday will be occupied by papers and discussions and the closing session On Wednesday, July 31, and Thursday and Friday, Aug 1 and 2, there will be final excursions to Grouville, Lisieux, Caen, Bayeux, Mont St Michel, and Rouen and district

Inquiries in reference to the meeting should be addressed to Mr T Sheppard, at the Museum, Hull, or to Dr A Loir, Comité Local, Hôtel de Ville, Le Havre, France

News and Views.

ON June 26 the centenary occurred of the death of James Lewis Smithson, who by his will, dated Oct 23, 1826, left his fortune "to the United States of America to found at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge among men" Born in France in 1765, Smithson was the illegitimate son of Hugh Smithson (1715–86), who married the heiress of the Percy property, took the name of Percy, and in 1766 was made Duke of Northumberland, and of Mrs Elizabeth Macie, widow of James Macie, of Bath He was known during the first half of his life as James Lewis Macie, and under that name he entered Pembroke College, Oxford, graduated as M A in 1786, and was the following year admitted a fellow of the Royal Society His attainments in chemistry and mineralogy were vouched for by Kirwan, Blagden, and Cavendish, and Smithson's life was mainly devoted to scientific studies He travelled and lived much abroad, counted among his friends and correspondents, Davy, Thomson, Cavendish, Biot, and Arago, contributed some 27 papers to the *Philosophical Transactions*, Thomson's *Annals of Philosophy*, etc, and collected a great mass of notes on various subjects His death took place at Genoa, and his grave, until the end of 1903, was to be seen in the little English Cemetery on the heights of San Benigno overlooking the Gulf of Genoa Early in 1904 his remains were exhumed and, under the supervision of Alexander Graham Bell, conveyed to Washington, where they now lie in a mortuary chapel in the great institution founded through his action

SMITHSON'S fortune came to him through his mother, who could claim descent from Henry VII and was connected with the Hungerford family of Studley In his will he directed that his property should first go to a nephew, Henry Hungerford, and it was in the case of his nephew's death that it was to go to the United States It was not until 1837 that any of the money was received in America, and a further nine years elapsed before Congress decided to accept the trust and found the Institution The Board of Regents designated by the Government met on Sept 7, 1846, and one of their first acts was to appoint Prof Joseph Henry, of Princeton, as secretary It is not too much to say that it was largely owing to Henry's foresight, energy, and broad mindedness that the Smithsonian Institution soon gained an international reputation Henry has been succeeded by Spencer Fullerton Baird (1878–87), Samuel Pierpont Langley (1887–1906), Charles Doolittle Walcott (1907–1927), and the present secretary, Dr Charles Greeley Abbot "Smithson's wishes", wrote Langley thirty years ago, "have been carried out by those immediately administering them with a constant scrupulous thought of the intent of the founder, while in doing this the best results have flowed from a rigid construction of his own words, so briefly expressed, and from a division of the activities of the Institution into two great distinct but parallel paths, the 'increase' and 'diffusion' of knowledge" The motives which led Smithson to leave his money to the United States will probably remain unknown, but we are in no doubt as to the admirable manner in which his wishes have been carried out or of the fruitfulness of his bequest

IN his presidential address to the Pharmaceutical Conference in Dublin on June 25, Mr R R Bennett dealt with some aspects of materia medica in which a rational use of drugs has replaced a crude em-

principism, owing to recent advances in chemistry and physiology and in the science and practice of medicine Such increased knowledge has led to improvement in the public health, and to the discovery of new remedies the beneficent effects of which are world wide in their application In the tropics especially, knowledge of the natural history of parasitic diseases and the discovery of drugs exerting a curative effect have led to a measure of control which makes available for human habitation large tracks of otherwise unhealthy country In this work the part played by synthetic drugs is of great importance but in spite of the discovery and use of powerful new remedies our knowledge of the relationship between chemical structure and physiological action is fragmentary It can only be increased by the systematic preparation of new compounds and the examination of their pharmacological properties In this connexion the establishment of a chemical research laboratory at Teddington under the general scheme of research directed by the Department of Scientific and Industrial Research must be regarded as an experiment of great interest In collaboration with the Medical Research Council, an endeavour is to be made to obtain experimental evidence of the relationship between constitution and activity

NEW remedies or methods of treatment are often of respectable antiquity Mr Bennett mentioned that ephedrine which has found a place in the treatment of asthma, is similar both chemically and pharmacologically to adrenaline it was isolated, but not used, fifty years ago the Chinese, however, have employed the crude drug for more than two thousand years Again, animal preparations were used as medicinal agents, only to fall into disfavour now they are coming into vogue again, and some exert a specific effect in certain diseases, for example, liver and its extract in the treatment of pernicious anæmia, or thyroid gland and its active principle, thyroxin, in the treatment of cretinism The tendency is to replace the crude drug with the active principle extracted from it, then the latter is prepared synthetically, often more cheaply than the natural product, and except for the fact that the synthetic compound requires resolution into the optically active isomers, it is identical with that prepared in Nature's laboratories But modern remedies include more than is implied under the term drug' organotherapy is assuming as important a place as chemotherapy, vitamins can be prepared in concentrated form, and, finally, bacterial products play an indispensable part in the treatment of many diseases Vaccination for smallpox, antitoxins for diphtheria or tetanus, and still more recently inoculation for canine distemper and yellow fever indicate the wide range covered by the modern use of the term remedy Finally, it must not be forgotten that physical methods also play their part, of which the use of radium in cancer may be considered a most notable example

THOUGH the loss of life was fortunately small, the earthquake that occurred in New Zealand on June 17 appears to have been the strongest felt in that country since 1855 The epicentre lay in the north west of the South Island, the greatest damage having been done at Westport Greymouth, and Murchison At these places scarcely a building escaped serious injury At Nelson a tower fell, so that the area of damage must have been more than 150 miles long in the south south west direction and about 50 or 60 miles in width In the epicentral area, landslips were unusually frequent and large, and indeed most of the fifteen deaths reported seem to have been due to landslips rather than to the fall of buildings Our record of New Zealand earthquakes is a brief one but in the century that has elapsed since 1826 no other prominent movement appears to have occurred in the centre recently in action The three great earthquakes of Oct 16 17 and 19 1848 visited a district fifty miles or more to the east, in the chain of mountains that runs south south west from Cloudy Bay along which a remarkable fissure 60 miles long was then formed The still greater earthquake of Jan 23 1855 occurred in the south east end of the North Island its epicentral area being in or near the continuation of that of the earthquake of 1848 With this earthquake, an area of 4600 square miles was raised from one to nine feet, the greatest elevation being along the line of the Wairarapa Valley

AMONG the recent additions to the British Museum (Natural History) are the late Dr J de Bedriaga's herpetological collections and a selection of books and pamphlets from his library, presented to the Department of Zoology by Dr G A Boulenger This collection (1306 specimens) is especially rich in representatives of the numerous races of the wall lizard from the islands of the western Mediterranean The books and pamphlets, 159 in number are almost all works or editions new to the zoological library of the Museum Dr Hugh Scott and Mr J Omer Cooper have presented to the Department of Entomology some 40,000 insects collected in Abyssinia during their expedition to that country in 1926–27 The entomology of the high plateaux of Central Abyssinia, where these collections were made, has been relatively very little investigated, but is of great interest owing to the peculiar mingling of tropical African, northern, and Oriental forms Certain small groups already worked out show a high percentage of species new to science

THE collection of Lepidoptera made by the late Mr A E Wileman during his thirty years consular service in Japan, Formosa, and the Philippine Islands, which consists mainly of moths and comprises some 25,000 specimens, including nearly 760 types, has been presented to the British Museum (Natural History) by Mrs Wileman in memory of her husband Dr J M Aldrich, of the United States National Museum, Washington, has presented a series of dried larvæ of a Saturniid moth, *Coloradia pandora*, Blake, from the Mono Lake district, California The caterpillars of this moth feed on the needles of a species of pine (*Pinus jeffreyi*) at an altitude of some 7000 feet, and are collected, dried, and used as food by the local Indians The life cycle of the insect occupied

two years, and, as an indication of the numbers in which the caterpillars sometimes occur, an Indian chief is said to have prepared a ton and a half of these larvæ during a single summer The Department of Mineralogy has received from Mr F N Ashcroft a further selection of about a thousand mineral specimens, representing more than a hundred Swiss localities With Mr Ashcroft's previous donations of Swiss minerals and those bequeathed by the Rev J M Gordon in 1922, the Museum now possesses the finest collection extant for illustrating the conditions of mineral growths in the special type of Alpine veins

SIR RICHARD GREGORY's presidential address to the Royal Meteorological Society last January, entitled "Amateurs as Pioneers", which has just been published (*Quar Jour Roy Met Soc*, vol 55, No 230), deserves to survive as a chapter in the history of British science Nowhere in the world has the amateur flourished as he has in Great Britain, and he flourishes still It has often been pointed out that, though it is easy to beat the Englishman in the field of high specialism and technique, if the view be extended so as to take in the larger number of amateurs and fairly good performers in any branch of study or of sport, Great Britain may face the world In this matter it is the same with tennis as with Greek, with chess as with meteorology Sir Richard is concerned mainly with contributions to the last named subject His contributors range from the Rev William Merle or Morley, who went from Oxford to be rector of Driby in Lincolnshire in 1331 and kept a systematic record of the weather for seven years, down to the amateurs of the present day, who have set up two way radio communication between England and the Antipodes on a wave length of 80 metres

METEOROLOGY has been a favourite field for the amateur In 1846, James Glaisher, following a long line of amateur observers, was able to correct a false conclusion published by the Registrar General as to the relative temperature of London and York As a result he was requested to collect suitable observations for inclusion in the "Quarterly Returns of Marriages, Births, and Deaths" He thereupon formed a band of 50 to 60 voluntary observers who became the nucleus of the Royal Meteorological Society and the pioneers of the Meteorological Office The exploration of the air has been the special triumph of the amateur The same Glaisher became famous as a balloonist, and some stirring pictures are published in this pamphlet of his experiences, ascending and insensible, at the height of seven miles The Royal Society itself, indeed, and practically all the pioneers of the seventeenth century, were amateurs, at a time when the universities were close in the grip of religious controversy and Aristotelian dialectics It was men out of touch with this who first came together in Oxford, and afterwards consolidated their efforts in the Royal Society in London They were mostly men of means, and it would be well for us if as large a proportion of that class were amateurs of science to day

SINCE 1846 the only material changes in the scope of the United States National Museum have been the addition of a department of American history, and in 1920 the separation of the National Gallery of Art as a unit Now, as the Report for 1928 shows, there is imperative need for further accommodation for purposes both of exhibition and storage of study collections Especially, it would appear, has natural science suffered, since exhibits of animals have been curtailed to make way for historical subjects, and space designed for anthropology has been pre empted for objects of art In view of this contraction of natural science in favour of other studies, we turn with interest to the records of visitors, which give an indication of the comparative interest taken by the people in the different groups of exhibits In the first complete year in which natural history is treated as a separate group, the number of visitors to this section was 151,112, while 'arts and industries' claimed 207,010 But now (1927–28) the numbers are respectively 618,773 and 517,238, and this scarcely gives the true contrast, for a glance shows that natural history must have claimed on an average during the last eighteen years about 200,000 additional visitors a year Thus the public gives little excuse for extending art at the expense of natural history A large part of the Report deals with the activities of each of the departments, in acquisition, research, exchange, and so on The extent of the collections which have now been amassed may be judged by the fact that the department of geology possesses more than two million specimens, and biology well over eight million It is sad to read that of the 333,329 birds in the collection, 8126 have been classed as alcoholics '—and this in a dry land

ON Jan 5, 1927, the Governor General of Canada in Council gave authority "to designate the Museum branch of the Department of Mines the 'National Museum of Canada'" Thus the Museum publicly assumes a national relationship towards which its activities have been broadening since it began as a part of the Geological Survey of Canada in 1841 During that developmental period, many changes have taken place Gradually the purely geological activities have had added to them anthropology, biology, and palæontology, each now claiming a division of its own At the same time, various transferences of site have moved the Museum, first from its original home in Montreal to Ottawa in 1880, and there, finally in 1910, to the handsome Victoria Memorial Museum, where the collections and staff have since been housed, except during a partial and temporary dispossession, from 1916 until 1920, when, their own Parliament House having been destroyed by fire, members and senators transferred their activities to the Museum building An account of the history of the Museum and of the developments due to each of its successive directors, from Sir William E Logan to the present day, has been written by the acting director, Mr W H Collins, for the Annual Report for 1926, just published, the first of a series of reports proposed to be devoted wholly to the interests of the National Museum of Canada.

THE Council for Scientific and Industrial Research for the Commonwealth of Australia has issued its second annual report (Canberra H J Green, 1929 1s 8d) The Council, being a new department, is still mainly occupied in building an efficient research institution to co operate with existing institutions in solving many pressing national problems Although some investigations have been initiated, the Council has principally taken over investigations that were in progress Four divisions, each under a chief, have already been formed They are animal nutrition, economic entomology, economic botany, and forest products A fifth division to deal with animal health is in course of formation So far the Council under takes to carry out extensive investigations only in those fields where it has been found possible to find a suitable chief of the division The report dwells on the lack of efficient research workers in Australia in the fields where work is most required, that is to say, in pastoral and agricultural problems A plea is made for the more extensive training of research workers in the biological sciences The difficulty is partly overcome at present by extensive co operation with the Australian universities and the State depart ments of agriculture The report contains notes on many valuable lines of research now under way

THE Australasian Antarctic Expedition (1911–1914) Scientific Reports, Series B, vol 2 (Terrestrial Magnetism and Related Observations), Part II, issued in March 1929, is devoted to a discussion of "Magnetic Disturbance and its Relations to Aurora", by the late Dr C Chree (Sydney Alfred James Kent 15s) Of the 132 pages in this part of vol 2, 53 are occupied by tables and 79 by text, it is to be regretted that no summary of the conclusions resulting from this long discussion is included Of the four chapters, one only is devoted to the connexion between auroræ and magnetic disturbance, when auroræ are specially intense, so also, in general, is magnetic disturbance, but on more ordinary occasions there appears to be no close relationship between the two phenomena, in the Antarctic The other chapters deal with daily and hourly character figures for dis turbance, the international daily character figures are found to be on the whole indicative of Antarctic as well as of non polar conditions

THE Department of Embryology in the Carnegie Institution of Washington has from the outset, under the late Prof Mall and now under Prof G L Streeter, pursued a policy of close association with other departments engaged in related work in its own institute and in the Johns Hopkins University and Medical School, as well as with the general medical profession The policy has been a fruitful one for the study of human development, for many of the re searches summarised in *Year Book* No 27 could only have been carried out upon material obtained from such outside contacts The programme of study is of the widest character More than forty investigations have been completed or were in progress during the year reviewed, to June 30, 1928 They included researches on the differentiation of primitive tissues from the mammalian egg, the origin of the human heart, the locomotion of white blood cells, organo genesis, and the functions of the corpus luteum and other ovarian structures A monkey colony recently established has yielded interesting results bearing upon the duration and symptoms of pregnancy and the act of parturition, while many studies have been devoted to the nervous system, particularly to the correlation between function and structure, and to the phenomena of growth in the higher primates and man

VOLUME 19 of "Contributions from the Jefferson and Cruft Laboratories of Harvard University" contains reprints of 72 papers by the staff and research fellows which have appeared mainly in American scientific journals during the years 1926–27 Ten of these papers are by Prof P W Bridgman, who has continued his work on the properties of substances under high pressures Prof E H Hall contributes five, mainly on the emission of electrons from the surfaces of bodies, and Prof Lyman four on ultra violet spectra Prof Duane and Dr R J Havig hurst, a research fellow, are responsible for ten on crystal analysis by X rays, and Prof R S Mulliken and two research fellows for eight on the relations between band spectra and electronic structure of the emitting molecule Dr J C Slater contributes five and Dr E E Witmer a research fellow, four on the structure of atoms and the bearings of wave mechanics on the subject Prof G W Pierce describes his magnetic oscillators, giving frequencies from a few hundred to 300 000 per second A rod of magnetisable material passes through the centres of two coils, one connected to the filament and plate, the other to the filament and grid of a valve with a condenser in the circuit The oscillating currents produce changes of length of the rod, and the apparatus is much more convenient than the piezo electric generator The volume maintains the high standard its predecessors have led us to expect from Harvard

WE have received a copy of the prospectus an nouncing the sixth great exhibition of chemical apparatus and machinery to be held at Frankfurt on Main on June 10–22, 1930 The brightly decorated cover shows the remarkable growth in size of success ive exhibitions since the first of its kind was held at Hannover in 1920, and it is confidently expected that the Frankfurt exhibition will excel in importance even that held two years ago at Essen Many foreign countries will be represented among the exhibitors, and members of the *Dechema* (*Deutsche Gesellschaft fur chemisches Apparatewesen*, Seelze, bei Hannover) will receive special privileges Frankfurt is described as the greatest centre of chemical industry in the world In addition to this, the manufacture of chemical machinery and apparatus has grown to very considerable importance in the neighbourhood The exhibition will be held in four large halls, which are housed in three main buildings, plans of which are given The main avenues in the exhibition bear the names of famous chemists—Liebig, Bunsen, Wohler, Emil Fischer, Nernst, Ostwald, Baeyer, Willstatter,

Goldschmidt, Raschig, and others The first hall will contain scientific apparatus and instruments for laboratory use, technical measuring instruments, and also the postal department, press rooms, and writing rooms In the second hall will be found porcelain and stoneware and products of the ceramic industry Machinery and appliances used in the industry of oils and fats are to be assembled in Hall 3, a section of which will be devoted to the chemistry of daily life, whilst in the fourth hall large technical apparatus and machinery used in chemical industry, together with complete exhibitions of plant and processes and also raw and other materials, will be found

The forty first Congress and Health Exhibition of the Royal Sanitary Institute will be held at Margate, at the invitation of the Town Council, on June 21–28, 1930

In Nature of May 25, p 795, Messrs C von Bonde and J Marchand described a case of 'Siamese twins' in the spiny dogfish We find that similar twin dog fish were caught by a trawler in the English Channel and landed at Newlyn on Aug 25, 1928, and a repro duction of a photograph of the specimen was published in the *Fishing Gazette* of Dec 22, 1928

Referring to the note on p 922 of Nature of June 15, on a course of electrostatic methods in biology in Basel, Mr R Keller points out that it is scarcely correct to state that he and his colleagues "are introducing physical methods into biochemistry" This has already been done by other workers The Prague school is specialising on certain electrostatic *microscopical* methods

In order to facilitate the work involved in preparing the annual publication of "Organic Syntheses", the editorial board has been fortunate in securing the co operation of Dr C F H Allen, of Tufts College, Mass, who is acting as secretary to the board All correspondence regarding 'Organic Syntheses" may be addressed to Dr Allen, who will receive contribu tions to be considered for publication in future volumes

The Old Students' Association of Faraday House Electrical Engineering College has this year elected Dr Alexander Russell as its president to com memorate the fortieth anniversary of his appointment on the staff of the College It was in 1882 that the Hammond Electrical Engineering College for training electrical engineers was founded, and it was in 1889 this was merged in the present Faraday House College Since then, some 2050 students have entered Faraday House, and of these more than 900 are members of the Old Students' Association A portrait in oils of Dr Russell, by Miss A M Burton, has been presented to the Governors by the artist's brother, Mr R G Burton, who was at Faraday House during 1912–1915, and is now with the well known firm of Messrs A Reyrolle and Co A reproduction of the portrait forms the frontispiece of the summer issue of the *Faraday House Journal*

The drawbacks to most of the radio receiving sets at present on the market are the difficulties con nected with keeping them thoroughly clean and in good condition, the periodic charging of the low pressure accumulators, and the replacing of the high tension batteries Those who use the electric light often wonder why electricians do not use the domestic electric supply and thus get rid of both accumulators and high tension batteries Good progress, however, has been made in this direction When the domestic supply is alternating current, it is not difficult to buy quite satisfactory 'eliminators' which require neither batteries nor accumulators With direct current sup ply the practical problem of abolishing the high tension batteries has been achieved and excellent progress is being made in the direction of abolishing the accumulators Messrs Claude Lyons, Limited, of 76 Old Hall Street, Liverpool, issue a catalogue called 'Getting the most out of Radio" The ordinary scientific reader who wants to know the latest develop ments in methods of receiving broadcasting will find this catalogue very instructive Much of the apparatus described has been made by the General Radio Com pany of America The products of several English manufacturers are also described Excellent hints are given of the best methods of keeping sets in con dition As it is very difficult to get piezo electric crystals large enough to give fundamental frequencies below 25 kilocycles, we are glad to see that magneto striction oscillators can be purchased suitable for low frequencies The same firm also publishes a booklet describing a 'clarostat', an instrument which does for high resistance what a variable condenser does for capacitance It provides a method of continuously varying the value of a high resistance The material used is a highly pulverised graphite intermixed with pulverised mica The resistance is altered by applying pressure This material should also prove very useful in the laboratory

Catalogue No 169 of Messrs Dulau & Co, Ltd, 32 Old Bond Street, W 1, just issued, gives particu lars of 1200 second hand works dealing with botany and horticulture The prices asked appear to be reasonable

We have received from M Paul Lechevalier, 12 Rue de Tournon, Paris, a copy of that firm's catalogue No 114 of second hand works relating to zoology, nearly 1800 in number, published for the most part outside the British Isles

We have received from Messrs J H Steward, Ltd, 406 Strand, London, a copy of their new cata logue of surveying, drawing, and nautical instruments The catalogue illustrates a wide choice of theodolites, levels, plane tables, compasses, aneroids, drawing instruments, etc Full specifications of the instru ments are given

A Special Clearance List of instruments has just been issued by the City Sale and Exchange, Ltd, 81 Aldersgate Street, London, E C 1 It is classified, and various sections deal with field glasses, telescopes, surveying apparatus, etc, with a miscellaneous group including microscope accessories, mathematical instru ments, and a 3 inch Watson's Student telescope Deferred payments can be arranged

THE latest addition to the valuable series of catalogues of Messrs Bernard Quaritch, Ltd, 11 Grafton Street, W 1, is No 426, which deals with upwards of 1600 works classified under the headings of botany, agriculture, early medicine and surgery, forestry, fruit culture, gardens and gardening herbals, modern medicine, and tobacco Many of the volumes offered for sale are rare

APPLICATIONS are invited for the following appointments on or before the dates mentioned —A principal of the Birmingham Central Technical College—The Chief Education Officer, Education Office, Margaret Street, Birmingham (July 1) A temporary lecturer in physics at the Birmingham Central Technical College—The Principal, Central Technical College Birmingham (July 1) An assistant in geography at the London School of Economics and Political Science—The Secretary, London School of Economics, Houghton Street, W C 2 (July 1) A demonstrator in botany—The Secretary, King s College, Strand W C 2 (July 2) An assistant lecturer (woman) in the Department of Education—The Secretary, King s College, Strand, W C 2 (July 2) A junior forestry inspector under the Department of Agriculture—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (July 3) A resident lecturer (man) in geography and mathematics—The Principal, Normal College, Bangor (July 3) A chief instructor in the Engineering (Production) Department of the Wolverhampton and Staffordshire Technical College—Clerk to the Governors Education Office North Street, Wolverhampton (July 4) A research student in experimental physics—The Registrar Trinity College Dublin (July 5) A professor of geology at the University of Glasgow—The Secretary of the University Court University, Glasgow An assistant lecturer in biology, who will lecture in botany and a part time demonstrator in biology—The Warden and Secretary London (Royal Free Hospital) School of Medicine for Women, 8 Hunter Street W C 1 A civilian education officer Grade III, at the Royal Air Force Electrical and Wireless School—The Secretary Air Ministry Gwydyr House, Whitehall, S W 1 A full time lecturer in modern languages (French and German) at the Royal Technical College, Salford—Secretary for Education Education Office, Chapel Street Salford A principal of the Kenrick Technical College—Director of Education Education Offices Highfields West Bromwich A lecturer in biology and mathematics at the Bishop Otter College — The Principal Bishop Otter College Chichester An assistant with experience of biological and physical apparatus for sales department—Messrs Griffin and Tatlock Ltd Kemble Street, W C 2

Our Astronomical Column.

THE DISINTEGRATION OF COMETS —Mr N T Bobrovnikoff contributes an important study on this subject to *Lick Observatory Bulletin* No 408 He has prepared statistics on all the comets for which good determinations of magnitude are available they are 94 in number There is shown to be a strong correlation between brightness and period, those of short period being less luminous It is assumed as a working hypothesis that all comets came into existence at the same time, and that those of shorter period, having approached the sun more frequently, have suffered greater disintegration It is found that the comets of extremely small perihelion distance do not conform to the regression line given by the other comets, which is tolerably straight It is concluded that some special action such as partial evaporation of the nuclei, comes into play at these small distances It also appears from the statistics that the proportion of light due to the nucleus alone is greater for the comets of short period, indicating that these have lost a larger proportion of their gaseous envelopes

The indicated rate of loss leads to the conclusion that comets cannot be original members of the solar system, the age of which is estimated at thousands of millions of years Mr Bobrovnikoff estimates their age at about a million years, and concludes that they were all introduced into the solar system at the same time He endorses a conjecture which F Nolke put forward in 1909 that comets were introduced into the solar system at a time when the sun was passing through a nebulous region in space There are great difficulties in seeing how they could fail to describe hyperbolic orbits in this case Friction with the surrounding nebula could not be invoked, for all adjacent regions of the nebula would have the same acceleration towards the sun Nor could resisting medium in the solar system be invoked, as a million years is so small a fraction of the age of the solar system that the density of such a medium would not be appreciably greater then than now The number of close approaches to planets would be far too small to explain the great host of comets

However every attempt to explain the origin of comets is accompanied by grave difficulties The present paper undoubtedly establishes some important points and advances our knowledge on the subject even if we hesitate to accept all its conclusions

STELLAR PARALLAXES WITH THE YALE TELESCOPE AT JOHANNESBURG —Dr H L Alden, who with Mr O Connell is conducting the photographic determination of stellar parallaxes at Johannesburg, publishes his first list of fifty stars in *Astro Jour*, No 921 It is satisfactory to note that the parallax found for Alpha Centauri, which is 0 755" for the mean of the components, is in almost perfect accord with Gill and Elkin s value obtained with the Cape heliometer That for Proxima Centauri is 0 783", as this exceeds the value for Alpha in nearly the same ratio as the proper motion does it confirms the conclusion that Proxima belongs to the Alpha Centauri system

After this system, our next nearest neighbour is the Barnard star, for which Alden gives the parallax 0 555" The next largest parallax on the present list is that of Epsilon Indi 0 286", the parallax of this star was previously regarded as rather uncertain, so the new determination is welcome There are on the list two other stars the distance of which is less than five parsecs, these are 70 Ophiuchi, parallax 0 209", and Omicron 2 Eridani, 0 200"

All the parallaxes are relative, and need to be increased by about 0 005" to reduce to absolute values The negative value − 0 005" was found for Alpha Orionis, this confirms the fact of its great distance and huge size The number of plates used for each star varies from 15 to 23, the average probable error of a parallax is 0 0068"

Research Items

MAGIC IN BENGAL —The *Indian Antiquary* for April and May contains a study on magic in Bengal by Dr Biren Bonnerjea Magic was largely practised by the ancient Hindus and survives to a considerable extent among the modern inhabitants of Bengal Iron is one of the principal weapons against evil spirits They will not touch anyone who has any thing of iron or steel on them and a married woman is safe from them because of her bangle of iron which is usually covered with gold A pair of betel cutters is kept under the pillow of a sleeping child and when a woman dies in child birth a nail or piece of iron is hidden in the folds of her dress so that her spirit may not return and take away her child A traveller may contract dangerous infection from strangers hence anyone returning from say Europe must be purified by the ceremony known as Prayaścitta consisting in the polling of the hair and eating or at least touching with the lips of cowdung Ambassadors of native princes on returning from England have been considered so polluted as to require to be re born In Chittagong at a difficult child birth the doors must be thrown open corks taken from bottles and dogs and other animals set free Amulets made of the teeth and claws of tigers and crocodiles are worn because these are the most dangerous of the animals of Bengal To ensure the health and well being of a child during the coming year water is poured over it on its birth day through a sieve which contains ten different kinds of flowers and leaves and bits of gold or silver Many of the simple acts of life have peculiar rituals of their own For example a woman who cleans out her ears after nightfall runs the risk of bodily injury but she may do it with impunity if she asks the permission of anyone present If she is alone she asks permission of the wall A precaution against the dangers attendant on the common acts of life is to snap the thumb and middle finger of the right hand

EDENTATES OF ARGENTINA —The University of Buenos Aires has published a monograph on Los Edentata Argentinos submitted by José Yepes for the degree of Doctor en Ciencias Naturales (*Revista Univ Buenos Aires* Ser 2 Section 5) The work which contains short descriptions and summaries of the distribution within the Argentine and beyond it and full synonymies is well illustrated and forms a handy guide for the identification of the various forms Several of the species of the South American edentates have developed well marked geographical races so that the number of forms of this odd group now distinguished in the neotropical region numbers sixty eight Many of these are wide spread so that Argentina contains in all nineteen forms, of which only six are peculiar to it The most outstanding of these since they represent distinctive genera are *Chlamyphorus truncatus* and *Zaëdyus pichiy* but *Chætophractus*, all the four forms of which occur in the Argentine is also a genus of restricted distribution confined to that republic and Bolivia

EMBRYONIC MORTALITY IN FOWLS —Even under the best conditions the poultry farmer suffers a considerable loss from mortality among embryos during incubation Mr F B Hutt and Dr A W Greenwood have made an investigation into the causes of such mortality and have examined more than 12 000 eggs which failed to hatch during incubation (*Proc Roy Soc Edin* vol 49 Pt 2, 1929) They find that one of the major causes of failure to hatch is the malposition of the embryo in the shell Four main malpositions are described One of these, in which the head is buried between the legs definitely prevents the embryo from chipping the shell and so hatching The other three by preventing access to the air chamber of the shell hinder pulmonary respiration and so suffocate the embryo A further cause of embryonic mortality is the abnormality known as chondrodystrophy The occurrence of this abnormality is independent of the breed of fowl sex of embryo and age of dam Its incidence is highest in January and February and declines steadily to almost complete absence in June The incidence is inversely proportional to the amount of sunshine and it is suggested that lack of direct sunshine is a factor in the etiology of the abnormality There is a suggestion that the causal agency is an hereditary physiological abnormality in the dam A further percentage of the embryos in the eggs which failed to hatch were actual monstrosities The various types are described and their frequency noted There is a decline in the incidence of monstrosities from February to June Ninety three per cent of the monstrosities were characterised by various degrees of abnormality either in the brain cranium or eyes or in the combinations of these organs It is suggested that monstrosities are caused by the arrest of the development of the embryo at a critical stage probably by the chilling of those eggs laid in the early stages of gastrulation

PHYSIOLOGY OF THE EMBRYONIC DEVELOPMENT OF EARTHWORMS —While there is a considerable literature on the morphological side of development of Oligochæta the physiological processes of the development have never been studied and a recent paper by P G Svetlov (*Travaux du laboratoire zoologique et de la Station zoologique de Sébastopol* Académie des Sciences Leningrad Série 2 No 13 1928) contains much of interest in this respect while the morphology of embryonic development is also treated very fully Of particular interest are the observations made by the author on the osmotic pressure of the fluid in the cocoons of the two species studied It was found that in *Bimastus constrictus* Rosa the osmotic pressure is very low, while in *Eisenia fœtida* Sav it is almost as high as in the blood of adult worms Osmotic pressure in the cocoons of both species is closely connected with that of the environment that is that of the soil water this necessitates the presence in *B constrictus* of a special apparatus for regulating the osmosis (osmo regulating blastomeres), in the case of *Eisenia fœtida* this apparatus undergoes a reduction because this species has a high osmotic pressure little influenced by the external conditions On the whole, however the embryos of both species are not particularly well adapted to the osmotic conditions of their environment The importance for ecological studies of the osmotic relations between cocoons of earthworms and the environment is strongly emphasised by these observations

GERMINATION AND VIABILITY OF FERN SPORES —Whilst studies of seed viability and the effect of external conditions on seed germination abound, similar studies upon the unicellular spores of ferns are much less numerous although such studies may throw considerable light upon the physiological problems connected with the maintenance of viability and conditions for germination, etc The very extensive studies by F Okada, described in the *Science Reports* of the Tôhoku Imperial University, Vol 4, No 1, series 4 of the germination of the spores of five species of ferns and the retention of viability

under different conditions are, therefore, particularly welcome Okada finds that the spores of *Equisetum*, which rapidly lose viability under almost any conditions of storage (10 24 days under laboratory conditions), contain nearly 50 per cent water on fresh weight, whilst the much more durable spores of *Woodwardia* (174 191 days under laboratory conditions) contain only about 6 per cent water The spores of several species of ferns failed entirely to germinate in complete darkness, the spores of *Equisetum arvense* and *Osmunda japonica* would grow under these conditions The catalase content of the spores was examined and in every case it diminished with increasing age

YEAST FROM A THEBAN TOMB —The principal feature of the current Jahrbuch " of the Gesellschaft fur die Geschichte und Bibliographie des Brauwesens, E V (Institut fur Gärungsgewerbe, Berlin) is an article by Prof J Gruss on the contents of a beer jar from the tomb of Wah a Pharaoh of the eleventh dynasty Mr H E Winlock, the leader of the expedition from the Metropolitan Museum of Art, New York, which opened the tomb in 1920 considers that although the jar was found on its side, it was probably upset when the stopper blew off, and the contents are therefore almost certainly 4000 years old The microscopic examination is illustrated by twelve plates, and revealed diatoms probably from the Nile water aluminium silicate crystals from the pottery, cloth fibres starch grains, and fragments of emmer Bacilli, pediococci, diplococci, and citromycelia were also found, and in addition an autogenic yeast similar to Digora, which Prof Gruss has named *Saccharomyces Winlocki* It is distinguished by elliptical or round cells 5 μ in diameter and has a close grained plasma and nuclear vacuole The yeast was also found with *Schizomyces ducens n spec* and aleurone cells in pieces of beer loaf from the same tomb, and it is noteworthy that these pieces are contemporaneous with bread in the Berlin museum found in the tomb of Mentuhotep in the same cemetery The chemical analysis of the loaf indicates the addition of honey for sweetening purposes and of a fruit of the *Citrus Aurantium* type to produce bitterness The same publication also contains several interesting articles on the medieval monastic breweries of Germany, and a note by F Schuster on the 'ferula', a carved wooden sceptre which was formerly the symbol of the skilled brewer in Germany Apparently the name is derived from the plant *Ferula L*, a variety of fennel, the stalk of which figured in Bacchus worship (Narthex), and therefore had a special significance for the brewer

VOLUME TABLES FOR INDIAN TIMBER —It is only during the present century that the preparation of growth and volume statistics has been commenced in the forests of the British Empire, and its inauguration was due to the Indian Forest Service Statistics of the kind are now available for some of the more important timber species of India and Burma, such as deodar, sal, and teak In a recent number of the *Indian Forest Records* (vol 13, Pt 3, Sylviculture Series, 1928) commercial volume tables for sal (*Shorea robusta*) in the wet mixed forests of the Bengal Duars are published Several volume tables for this species are already in existence, but they relate chiefly to the growth of this tree in the drier climate of the United Provinces The latter tables, it is considered, can be safely applied to the drier types of Bengal sal forest, as also to similar forest in Assam They are inapplicable, however, to the moist type and it is for this latter that the new tables are designed The preparation of such tables involves considerable field work in connexion with the measurement of the crops on selected areas of forest, work in which the compiler, Mr Parma Nand Suri, statistical assistant to the sylviculturist of the Research Institute, was ably assisted by the local forest staff The same officer has also prepared (*Indian Forest Records*, vol 13, Pt 4, 1928) a set of tables the first of their kind, for the sundri (*Heritiera Fomes*) in the Sundarbans, the Gangetic delta south of Calcutta These tables have been drawn up for the two types of sundri forest, the salt water type and the fresh water type They should prove of great assistance in estimating the outturn of coupes and volume of growing stock In connexion with the Sundarbans sundri volume tables, Mr H G Champion, sylviculturist at the Research Institute writes in a preface Since the work was begun there has been published *Burma Forest Bulletin* No 15 (December 1926), a quarter girth volume out turn table for this species, for the Delta division of Burma There is a very fair agreement in the small overlapping portion suggesting that if larger trees are grown in the Sundarbans the Burma figures may prove useful Both pamphlets are illustrated and furnish evidence of the great strides made in the scientific aspects of forest work in India

PROGRESS OF SURVEYING IN INDIA —The Report for 1925–26 of the geodetic branch of the Survey of India, which is dated July 1928, has a record of much work Geodetic triangulation was resumed with work in Lower Burma, after an interval of eight years Previous work in that area dated from 1875 High precision levelling occupied several detachments Tidal observations with automatic gauges were continued at eight ports There are now more than fifty stations in Indian waters, including the Persian Gulf and Red Sea, at which automatic tidal observations have been taken for a number of years Among other interesting matters on which the report touches is the value of bench marks on trees In Canada such bench marks have been used Their constancy has not been tested with any permanent mark of the land established in precise levelling, but the topographical survey does not disfavour their use At Dehra Dun experiments have been made on tree bench marks and eleven of them have been connected at intervals, during twelve years, with the standard bench mark in the Geodetic Office grounds The conclusions of those tests are that for secondary precision, as in irrigation work, a tree bench mark is sufficiently good, but is not constant enough for lines of high precision In all cases the mark should be placed on the heart wood and not on the bark of the tree

OIL AND GAS IN WESTERN CANADA —The economics of the Canadian oil industry have changed much since the two well known volumes on petroleum and natural gas in the Dominion, by F G Clapp, were published in 1914–15 Then it was the eastern provinces which were mainly responsible for production, especially Ontario With the gradual decline of these eastern fields, however, attention is naturally being concentrated on the more westerly developments, and the performance of " Royalite No 4 " well in the Turner Valley Oilfield, Alberta, 1924, which raised this province to the leading position of production in the Dominion, a position since maintained, has naturally had a strong influence in reviving interest in this region Alberta has always swayed popular feeling, equally scientific interest, by its famous gas fields, but search for large oil pools has not often proved encouraging, save the instance cited It is characteristic that new possibilities of oilfield development in the western hemisphere should be the occasion of renewed literary activity, so that the bulletin now appearing under the above title from the pen of

G. S. Hume (Department of Mines, Canada) has for some time been anticipated by oil technologists. It is also characteristic that such bulletins should include what we may term 'chapters of instruction for the uninitiated', a kind of condensed text-book outlining the general features of oil origin, occurrence, accumulation, structures, and so on, much as occurs in the previous volumes cited. A modern note in this 'text' is struck by a chapter on geophysical methods for locating oil, but it is doubtful whether this outline would do more than confirm an inexperienced operator in the opinion that the subject was far beyond his (the operator's) comprehension; technically, such a chapter is too brief and sketchy to be of any value. The descriptions of the oil and gas fields of the western provinces are more to the point, though unnecessarily burdened with detailed well logs. The maps and sections given are, however, most valuable, and the description of the Turner Valley field particularly good.

QUANTISED TRANSITIONS.—In the correlation of the terms of line spectra with the stationary states of atoms, considerable use is made of a number of quantum rules that express the possibility and the probability of various types of transitions. A generalisation of the theory upon which these are based has been made by J. A. Gaunt in a paper in the May issue of the *Proceedings of the Royal Society* on the relativistic theory of an atom with many electrons. He finds that the selection rules are valid if there are no external fields; the rule '$\Delta\Sigma k$ is odd' is equally rigorous even in a uniform magnetic field, and that the summation rule for the intensities in a multiplet is true to a first approximation. The greater part of Mr. Gaunt's paper is of a general nature, but one practical point to which he refers specifically is of some significance in astrophysics. Certain lines of nebular spectra have been attributed to forbidden transitions between stationary states of the doubly charged ion of atomic oxygen; if they have been correctly identified, it would seem that their emission must occur in an electric field or in a non-uniform magnetic field, since they have $\Delta\Sigma k$ equal to zero.

REFLECTION CAUSTICS.—A note in the *Transactions of the Optical Society* (vol. 30, p. 134) from the Optics Department of the National Physical Laboratory contains an interesting set of photographs of reflection caustics which were obtained by the double reflection of light within a photographic lens. The reproductions, in spite of the fact that they do not show all the finer details of the original, include a number of beautiful patterns, mostly built up of various elliptical and cusped curves, and are of considerable interest as illustrations of an aberration which is not often encountered now in optical instruments. The usual absence of this effect, it is suggested by the authors, Messrs. T. Smith, J. S. Anderson, and L. C. Cordle—is possibly due to the fact that the main interest is now centred in systems so well corrected that faults of this type are masked by diffraction, and the caustics only reappear when the lens is used under conditions different from those for which it was designed. The same issue of the *Transactions* contains a pair of coloured reproductions of the appearance presented by a test bar when examined in plane polarised light and in circularly polarised light in the Coker strain testing apparatus, which are also of considerable educational value.

MAGNETOSTRICTION.—The phenomena of magnetostriction are anomalous in that, in spite of the way in which they are observed, they are far too large to be explained by purely magnetic forces. The corresponding difficulty which arises in connexion with Weiss's molecular fields in iron and similar bodies has recently been removed by Heisenberg's theory of ferromagnetism, which is based upon the 'exchange' properties of electrons, and it has now been shown by R. H. Fowler and P. Kapitza that the same theory can be extended with very little elaboration to include all the essential facts of magnetostriction and the phenomena of the Curie point. One striking feature of their paper on this subject in the issue of the *Proceedings of the Royal Society* for May 2 is the scarcity of accurate experimental data by which the theory—in itself still far from complete—can be tested. So far as magnetostriction is concerned, experiment does appear to be well ahead of theory, but the measurements of the allied change in the size of specimens when they lose their intrinsic magnetisation at the Curie temperature are particularly unsatisfactory. The experimental values for the changes in the specific heat at the Curie point are also perhaps uncertain, although they do suffice to show that nickel has probably one magnetisable electron per atom, whilst iron and magnetite have two or three effective electrons, the latter both being cases for which the quantum analysis has still to be constructed. Heisenberg's theory will require to be considerably extended before it can account for all the complex features of ferromagnetism, but it has certainly already removed the subject from its previous somewhat isolated position, and has at the same time emphasised the need for further experiment and indicated the lines upon which it should be attempted.

SOME PHYSIOLOGICO-OPTICAL EXPERIMENTS.—Prof. Bohuslav Brauner has recently communicated to the Bohemian Academy of Sciences a paper describing some remarkable physiologico-optical experiments which he first made fifty-five years ago under the inspiration of Helmholtz. He afterwards discussed them with the late Prof. Deyl, a prominent Central European ophthalmist, who was impressed by their novel character, and as they have never been published, Prof. Brauner was persuaded to lay them before the Bohemian Academy. The first to be described relates to artificial blindness, which can be induced by throwing the image of a well-illuminated body upon the blind spot of the retina. Thus, when the image of the moon is projected upon the blind spot, total blindness results in a few seconds. Other remarkable experiments concern the visibility of the observer's eye and stereoscopic results without the use of a stereoscope (results acquired after some practice in making the axes of the eyes parallel or crossed as circumstance and effect demand). In this connexion one of the experiments described is an amplification of an observation by Pouvilliers (see NATURE, April 14, 1923, p. 511). It appears that when two identical contour maps placed side by side with their centres 62 mm. apart were observed with the axes of the eyes nearly parallel, a double superposed picture much larger than the originals is observed in the middle, apparently below the level of the paper. The mountains stand out higher according to their contours, so that a relief map is obtained. When viewed with crossed axes, the combined picture is apparently much smaller than the originals, both of which are here pushed farther apart and appear relatively larger. In this instance the summits of the mountains appear as funnel-shaped depressions. It would seem that some of the effects obtained by Prof. Brauner can be explained by the fact that the accommodation of the eyes changes automatically with the change of the angle of the ocular axes.

South Africa Meeting of the British Association

PROGRAMMES OF SECTIONS

MATHEMATICS AND PHYSICS

AT the forthcoming South Africa meeting, Section A (Mathematics and Physics) will be under the presidency of the Right Hon Lord Rayleigh Representatives from Great Britain of all branches of the Section will support him and will communicate papers in the two centres of the meeting, Cape Town and Johannesburg Prof Hevesy, who is a foreign guest, will open a joint discussion with the Section of Chemistry on quantitative chemical analysis by X rays and its applications, and a second joint meeting, in this case with the Section of Geography, will be held for a series of papers on geodesy and surveying Recent work on atomic nuclei will be described by Sir Ernest Rutherford and Dr Aston, and spectroscopic papers presented by Prof McLennan, Prof A Fowler, Mr R H Fowler, and Mr A C Menzies Some aspects of the work of the National Physical Laboratory, to be dealt with by Dr Ezer Griffiths, should bring to the notice of South Africans the important part played by the Laboratory in the scientific and industrial life of Great Britain In Cape Town itself, some interesting communications are expected from Prof Ogg and his colleagues in the University of Cape Town

Cosmical physics, already strongly represented in South Africa itself, will receive the aid of Prof de Sitter as a foreign guest, the Astronomer Royal, Prof Eddington and Prof Chapman Lastly, the claims of mathematics will be met by papers from Sir Gilbert Walker, Mr F P White, and Dr Wrinch

CHEMISTRY

THE address of Prof G Barger as president of Section B (Chemistry), will be delivered at Cape Town, and is entitled "Applications of Organic Chemistry to Biology" Organic and biochemical subjects occupy the major portion of the Cape Town programme Prof K Freudenberg, of Heidelberg, will give a lecture on 'The Vegetable Tannins", a subject of special interest in South Africa, and it is hoped to hear an account of "Essential Oils from South African Plants" by Prof St J van der Riet, of Stellenbosch Although the nature of vitamins from the chemical point of view was discussed so recently as the Leeds (1927) meeting, the rapid development of our knowledge of the vitamins since that time makes the joint discussion with Section I (Physiology) particularly opportune On the one day at Cape Town devoted to general and inorganic chemistry, Dr N V Sidgwick will give a lecture on "Chemical Linkage" and Prof J Smeath Thomas, of Cape Town, will give an account of "Recently discovered Nitrate Deposits in S W Africa" From Cape Town it is hoped that the Section will have the privilege of visiting the factory of The Cape Explosives Co at Somerset West

The sectional programme at Johannesburg is to be devoted almost entirely to inorganic and physical chemistry Mr H A White, of the Geduld Proprietary Gold Mines, Ltd, is to give an account of "The Chemistry of Gold Extraction", and two special features of the Johannesburg programme are a joint discussion with Section A (Physics) on "Qualitative Analysis by X rays" to be opened by Prof G Hevesy, of Freiburg, and a lecture by Prof E C Franklin, of Stamford University, California, on "The Ammonia System of Compounds" Mr A C Egerton is to give an account of "The Influence of Antiknocks on the Combustion of Hydrocarbons", and other important contributions to the programme are being made by Prof H Bassett and Dr F H Constable

GEOLOGY

THE organisation of Section C (Geology) has been necessarily affected by the meeting of the International Geological Congress at Pretoria, and a programme has been adopted which, while enabling the section to carry on its work with the Association, yet allows its members to take some part in the proceedings of the Congress Two sessions will be held at Cape Town and two at Johannesburg Members of the Congress who wish to be present and take part in the proceedings at Johannesburg will be able to take advantage of the invitation which has been extended to them

Sir Albert E Kitson, of the Geological Survey of the Gold Coast, president of Section C, will deliver his address at Johannesburg on "The Utility of Geological Surveys to Colonies and Protectorates of the British Empire"

The special position that Africa takes in all questions involving continental drift makes the joint discussion with Sections D (Zoology) and K (Botany) specially appropriate Phases of the problem may be touched in the papers by Prof W T Gordon on "Some Limestone Erratics from the Beardmore Glacier", and Mr W N Edwards on "Triassic Rhætic Floras of the Southern Hemisphere" Dr F Dixey will describe the geology of the Lower Shire Zambezi Basin and Mr F P Mennell will put forward "Some Suggestions as to the Origin of the Diamond Pipes" Of wider interest is the paper of Prof P G H Boswell on "The Precipitating Action of Colloids on Fine grained Sediments" this opens a new field of investigation

As is usual with Section C, the excursions are a feature of the programme As these have been arranged by Dr A L Hall, of the Union Geological Survey, and secretary of the International Geological Congress their interest and importance is assured Two half day and one whole day excursion will be made in the neighbourhood of Cape Town The journey from Cape Town to Johannesburg will be spread over four days with stops at Laingsburg and Kimberley Between the two sessions at Johannesburg members will be able to join the Congress for the Witwatersrand excursion (three days)

GEOGRAPHY

THE president of Section E (Geography) for the South Africa meeting is Brigadier F M Jack, Director General of the Ordnance Survey, who will deal with "National Surveys" in his presidential address Following this a series of papers will be read by Capt McCaw, Dr Van der Sterr, and others, dealing in further detail with cartographical and survey problems relating to Africa in general, and to South Africa in particular In connexion with these, it may be recalled that at the Glasgow meeting the Section emphasised the importance of completing as soon as possible, the survey of the arc of the thirtieth meridian, and urged also the need for the publication of a uniform series of maps of Africa on a scale of 1 2,000,000, as the only satisfactory base for various distributional studies in Africa The significance of the latter will be further developed, along with other points, in a report to be presented by Mr A G Ogilvie of a special committee which has been investigating problems connected with the geography of tropical Africa

Various aspects of South African geography—both physical and human—will be analysed, both at Cape Town and Johannesburg, by local authorities, including Prof J H Wellington and Prof E Walker At Cape Town, Mr Van Reenen, chairman of the

Irrigation Commission, will review various problems connected with the utilisation of available water supplies in South Africa, while Prof Serton will examine critically the extent to which the term 'desert' may be justifiably applied to various regions of low rainfall (for example, the Western Karroo, with an average annual rainfall of less than 5 inches in parts)

A meeting in a region of winter rains such as south western Cape Colony provides a fitting opportunity for a critical survey of "the Mediterranean Climatic Type, its World Distribution and the Human Response", which Dr Marion Newbigin proposes to undertake The various important problems connected with the South African sector of Antarctica will also be presented in a paper prepared by Mr F Debenham, and it is hoped that General Smuts will take part in the discussion on the matters raised

The position of geography in South African education is not all that can be desired, and attention will be directed to this important aspect in a joint discussion that has been arranged with Section L at Johannesburg, a whole morning being devoted to the question

Outside of Africa various interesting papers are being presented dealing with parts of both the southern and northern hemispheres The significance of China's expansion in the Far East is to be considered by Prof P M Roxby, while among the papers on Europe will be one by Prof H J Fleure analysing the significance of various city types in the interpretation of the different cultural regions of the Continent

Dr Vaughan Cornish's interest in the æsthetics of scenery is now well known in Great Britain and a paper by him on "The Rural Scenery of England and Wales" will be welcomed in South Africa

ECONOMIC SCIENCE AND STATISTICS

THE programme for Section F (Economic Science and Statistics) of the British Association has now been arranged for the forthcoming meeting in South Africa, and, as was to be expected, special attention is to be devoted to those economic problems which are of importance in the Union Labour questions, for example, are to be discussed in the light of South African conditions, and for this purpose a joint discussion has been arranged with the Anthropological Section on "Economic Competition between Advanced and Backward Peoples", while Prof A Leslie is to speak on "Coloured Labour and Trade Unionism in Cape Town" Another economic topic of considerable importance to South Africa is the marketing of agricultural produce and the joint meeting which has been arranged with the agriculturalists on "The Problem of Stabilising Agricultural Prices, with special reference to Control Boards, Equalisation Funds, and other methods of Price Regulation", should lead to an interesting discussion It is anticipated that Mr R B Forrester, Dr Tinley, and Mr R J Thompson will participate in this discussion At Johannesburg, Dr J E Holloway is to speak on "Population Problems of South Africa", while Mr W H Clegg will describe "South African Banking"

ENGINEERING

ENGINEERS attending the South Africa meeting of the British Association will have papers and discussions at both Cape Town and Johannesburg The president of Section G (Engineering), Prof F C Lea, will deliver his address at Johannesburg

The principal subjects chosen for papers are of great importance to South Africa At Cape Town Dr Ezer Griffiths, of the National Physical Laboratory, and Mr E A Griffiths, of Cape Town, will give papers on recent research work carried out in England and South Africa in refrigeration The successful export of fruit from the Union depends largely on this work

The importance of transport, which is as great in South Africa as in any other country, will be dealt with from many different angles by English and South African authorities Sir Henry Maybury will describe the developments which have taken place in Great Britain during the past few years, referring to the effect of recent legislation on road administration Papers dealing with transport costs, alcohol fuels, railways, and roads as feeders to the railways will also be given Sir Henry Fowler's paper will describe chiefly the work of the Directing Committee, of which he is a member, appointed by the British Government to study aspects of mechanical transport likely to further the economic development of the overseas Empire and it is hoped that the discussions on these papers will be of great help to this committee

At Johannesburg cheap power will be dealt with Sir Charles Parsons will give a description of the more recent developments in steam turbine practice, chiefly in regard to the increased output per unit

Prof E W Marchant's paper on the limits of the economical transmission of electrical energy will have an added interest, for at the last South Africa meeting of the Association the late Prof Ayrton made an important contribution on the transmission of power from the Victoria Falls Mr C H Merz will describe the development of the national scheme of electricity supply in Great Britain, and discuss the anticipated economies and the probable effects of the cheapening of electric power on the distribution of population and industries

The acute problem in mining in South Africa is the cooling and ventilation of the deep mines, and the joint discussion of the Engineering and Physiological Sections on deep mine ventilation, to take place at Johannesburg, should prove very valuable

ANTHROPOLOGY

SOUTH African anthropologists have prepared a full and interesting programme for Section H (Anthropology), in which archæology figures largely There is ample evidence, however, that other branches of the science are not neglected in the Dominion, and it has been necessary to make arrangements for a subsection at Johannesburg to provide for a number of papers on physical anthropology by Prof Dart and other members of the Anthropological School which centres in the University of the Witwatersrand At Cape Town especial interest will attach to a series of papers on the Fish Hoek Caves, which will be followed by a visit to the caves themselves The meeting at Cape Town will, however, be curtailed to allow the members of the Section to proceed in advance of the main body to Kimberley, where the collection of skulls and archæological exhibits in the Museum will be visited, Mr Cronin's remarkable collection of photographs of South African natives will be viewed, and archæological excursions in the neighbourhood will be made

The programme at Johannesburg will be particularly interesting Prof Dart will exhibit the Taungs skull, and arrangements have been made for a visit to the site of discovery Mr Leakey will describe his discoveries in the prehistory of East Africa, and Mr. Wayland will deal with the present position of Stone Age research in Uganda Mr C von Riet Lowe will deal with the archæology of Sheppard Island, with an addendum on the associated fauna, and Prof. Dart will describe mammoths and other fossil elephants of the Transvaal, some of them not previously known.

The question of Bushman rock engravings will be discussed by Miss Wilman, a subject on which much illuminating discussion may be expected, in view of

the visit of L'Abbé Breuil to South Africa as a guest of the Association and the demonstration of the Late Palæolithic art of Spain which he will give at Cape Town Members of the party proceeding from England—Prof Fleure Prof Ruggles Gates, Miss Murray, and others—will contribute to the pro ceedings

The items in the sectional programme however, which are expected to arouse the keenest interest are the papers centring around Zimbabwe Dr Leo Frobenius will give an account of the explorations of prehistoric Rhodesia made to date by the expedition of which he is leader He will be followed by Miss Caton Thompson who will describe the results of the work undertaken at the request of the Association which she has carried out at Great Zimbabwe and on which she has been engaged since the beginning of the year on behalf of the Association

PHYSIOLOGY

SECTION I (Physiology) this year includes in its programme one or two unusual items Probably the most striking is a joint discussion with the other biological sections on The Nature of Life ', which General J S Smuts has promised to open Among the other speakers on this topic are Profs D'Arcy Thompson, J S Haldane, Wildon Carr, and E C C Baly That an agreement will be reached is more than can be expected, but it is certain that much of interest will be said

The Capetown part of the programme also includes joint meetings with Section D on experimental biology, one morning being mainly occupied by papers on this subject, and an afternoon being devoted to de monstrations on kindred topics in Prof Lancelot Hogben s new laboratory Many of the contributions, both here and at Johannesburg are from South African workers, and the matters discussed range over a wide field

At Johannesburg the most important feature prob ably is a joint discussion with Section G (Engineering) on Problems connected with Deep mine Ventila tion ' The economic importance of this matter is very considerable, and it is hoped that members of the Transvaal Mining and Metallurgical Society will also be able to participate

Of almost equal interest to physiologists and to economists is "The Problem of Dust Inhalation", on which also a discussion has been arranged The sectional programme is now, however, restricted to questions connected with the mining industry Papers are being contributed by local workers on the measure ment and effects of ultra violet light, and a varied programme includes a paper by Dr Monckton Cope man on "Diet and Cancer", and a description of "The Feeding Habits of Vampyrella", with kinemato graph accompaniment, by Prof F E Lloyd, of McGill University

PSYCHOLOGY

SECTION J (Psychology) meets this year under the presidency of Mr F C Bartlett, the Director of the Cambridge Psychological Laboratory, who in his address will discuss 'Experimental Method in Psychology" The programme is full and varied, in it nearly every department of psychology is repre sented A joint discussion has been arranged with Section L on "Psychological Tests in Relation to Education and Vocational Guidance" in which papers will be read by Prof Reyburn, Dr C S Myers, and Dr Shepherd Dawson

South African psychologists will present seven or eight papers, three of which, by Prof Wilcocks, Prof E[illegible]rs, and Dr Fick, will report the results of investi gations into the intelligence of South African children both white and black The philosophical aspects of psychology are represented by Prof G Dawes Hicks in a paper on The Notion of Fusion in Psychology by Prof H Wildon Carr, who will speak on Imagina tion and Reasoning and by Prof Forsyth of Bloem fontein who will read a paper on the Significance of Holism , a philosophical theory propounded by General Smuts

The Industrial Fatigue Research Board is repre sented by Mr Eric Farmer, who will give an account of some of his own work on accident proneness

BOTANY

SECTION K (Botany) has a very full programme both at Cape Town and at Johannesburg The large number of papers to be communicated by South African workers indicates clearly the very active interest which is being taken there in botany at the present time All branches of botany are well repre sented in the programme Prof Seward s presidential address on Botanical Records of the Rocks will be given at Johannesburg As might be expected much time will be devoted to papers on the South African flora and there will be a discussion on its origin and evolution in which Dr Marloth Prof Bews Prof Compton Dr Pole Evans Prof Adamson Prof Moss, and others will take part Dr Pole Evans will also give an account of the present position of the botani cal survey of South Africa Prof F E Lloyd will exhibit a film illustrating the mechanism of the trap of *Utricularia* and Dr A S Hitchcock of the Smithsonian Institution will speak on the subject of grasses in relation to man Miss Saunders will discuss her recent work on carpel morphology

Popular lectures will be given by Dr Margery Knight on Seaweeds, a Study of Adaptation and Opportunity , and by Prof Priestley on From Lake to Veld a Study of the Water Relations of the Higher Plant The forestry group also has an interesting programme in which contributions from persons interested in forestry problems in South Africa are prominent Numerous excursions to places of botanical interest have been arranged

EDUCATION

THE programme of Section L (Educational Science) is promising and varied Two objects have been kept in mind in its preparation (a) the desirability of showing the recent development in educational ad ministration, practice, and teaching in England, and (b) the presentation and discussion of South African problems

Dr Kimmins has chosen for his presidential address the subject Modern Movements in Education ' One session at Cape Town is to be devoted to general educational problems in South Africa when five separate papers will be given by leading experts

At Johannesburg a full session will be devoted to 'Education and the Native Races , four papers being expected At a joint session with Section J at Cape Town, leading psychologists from both countries will discuss psychological tests in relation to education and vocational guidance Other sessions at Cape Town will be given to discussions on the relation of examinations to the secondary schools and on the teaching of science, including biology and botany, in schools At Johannesburg, at a joint session with Section E, papers will be given on the teaching of geography by members from both countries

Committees of the Section will also present reports on science in the school certificate, formal training and training for life overseas

AGRICULTURE

PERHAPS the most significant development which has taken place in agricultural science is the realisation of the very close relationship between soil and animal nutrition problems as they exist in Great Britain and the various Dominions of the Empire.

The fact that much of the work in progress in the British Isles has a direct bearing on Dominion problems has resulted in a desire for closer touch and collaboration between research workers in various parts of the Empire. This trend was emphasised and focused at the Imperial Agricultural Conference in London in 1927 and practical recognition has been given by the creation in the British Isles of Agricultural Bureaux in Soil Science, Animal Nutrition, Plant Breeding, Animal Genetics, and Veterinary Science. It is fitting, therefore, that by far the greater part of the programme for Section M (Agriculture), which is meeting at Cape Town and Pretoria, should be occupied by the discussion of broad agricultural problems. Two whole sessions are being devoted to soil problems, the first at Cape Town to a discussion on soil fertility and its control, and the second at Pretoria to methods of soil investigations in field and laboratory.

A morning session will be occupied by a discussion on Empire wool growing problems with particular reference to South Africa and to the manufacturing requirements of Great Britain. Grassland and the production of stock is another problem of world wide range, the fundamental aspects of which are similar in all parts of the Empire. Major Walter Elliot will open a discussion on the mineral aspects of pasture nutrition in relation to the live stock industry, and representatives of the Rowett Research Institute, Aberdeen, and the South African Veterinary Research Station will contribute.

The possibility of stabilising agricultural prices and the methods of achieving the object in view continue to exercise the minds of farmers and economists the world over, and considerable experience has been acquired in South Africa, Canada, and New Zealand. Section M has arranged for a joint discussion with Section F (Economics) on this subject, with particular reference to the operation of control boards, equalisation funds and other methods of price regulation. Agriculture and the Empire will form the subject of Sir Robert Greig's presidential address to Section M, and the address, together with a discussion on Empire agricultural problems, will occupy the whole of the second morning session at Pretoria.

Some Function Problems attaching to Convergence[1]

THE arrangement of the conducting paths of the nervous system, branching and redistributing their impulses as they do, exhibits places where numerous convergent paths run into one. When at such places two or more of the converging arcs are concurrently active, the trains of impulses arriving by them can interact. Such convergent places are co-ordination points. An example of much importance, and relatively accessible to experiment, is that in the spinal cord, where the motor nerve cells innervating a muscle receive as a group the various afferent paths which reflexly operate the muscle. If two or more of the convergent afferent nerves are excited concurrently, the reflex interaction, as revealed by the muscle, exhibits three main sets of cases.

In one set of cases the muscular response under concurrent stimulation of two or more afferents shows a deficit in amount as compared with the sum of the responses obtainable from the several afferents taken separately. This occurs especially when the excitation of the reflexes is strong; it is most marked when they are of maximal strength. The contraction effect of one afferent may default altogether. The result might seem to indicate inhibition, but analysis shows that it is not referable to any form of inhibition.

The explanation lies in the limitations of the mechanical response of the muscle fibres of the motor units activated: the contraction effect pertaining to one afferent being 'occluded' for the time being by that pertaining to another. 'Occlusion' is a result of the overlap of different afferent arcs upon the same motor units: this overlap is 'central', for example, in the spinal cord. The amount of 'occlusion' as observed by the myograph gives a measure of the amount of that 'central' overlap. In such estimates, however, the assumption is made that the component motor units of the muscle all of them possess individually the average value of contraction tension which obtains for them. This in the knee flexor (cat) semitendinosus has a value which is only one third of that obtaining for gastrocnemius. It is, however, certain that the individual motor units differ considerably in contraction value within one and the same muscle. Examined by occlusion, the overlap of the constituent branches of a single large afferent nerve upon its motor units can be well above tenfold. This gives a functional picture in harmony with the histological picture furnished long since by Cajal.

In another set of cases, on the contrary, the contraction response of the muscle, under concurrent stimulation of two or more reflex arcs which are excitatory for it, shows a surplus of contraction as compared with the sum of the responses to the component afferents taken separately. This result is most evident with weak reflexes. As with the other set of cases this result also, although opposite to the previous class, brings evidence of the overlap of the convergent arcs upon the central ends of motor units held by them in common. Moreover, evidence is thus furnished that central states of excitement, individually too weak to provoke the motor units into discharging activity, can by summation become effective for that activation.

The reflex excitation provoking contraction of the muscle is shown to be accompanied regularly in the spinal centre by concomitant subliminal excitation in other spinal motor cells over and above those excited to actual discharge. The time relation of central subliminal excited states obtaining in certain typical reflexes has been determined (J. C. Eccles). By the summation of subliminal excited states this fringe of subliminal effect is a functional means of liaison enabling co-operation between different adjuvant parts of the nervous system. Although the neuron upon which convergent arcs interact is subject to their combined influence, and is to that extent an instrument passive in their hands, it is an instrument clearly with ways of its own. Thus, to receipt of a single stimulus it may react by a response consisting of a whole tetanic series of impulses.

Another and third set of cases arising from interaction at the convergence point is where the upshot is inhibition. The clash is between 'central' excitation and a central process which arrests or precludes it, but about which all that is known is that it antagonises excitation. Evidence was adduced of

[1] Summary of the David Ferrier Lecture delivered before the Royal Society on Thursday, June 20, by Sir Charles Sherrington, O.M., F.R.S.

quantitative interplay of the opposed influences upon the individual neuron Conditions favouring inhibition were discussed

Though trains of impulses are the sole reactions which enter and leave the central nervous system, it is clear that nervous impulses are not the sole reactions functioning within that system States of excitement which can sum together, and states of inhibition which can sum together, and states which represent the algebraical summation of these two, are among the central reactions The specific cell units, the neurons, far from behaving merely as passive recipients and transmitters of impulses, modify as well as transmit what they receive

Joint Russian-German Expedition to the Pamir

A JOINT expedition to the Pamir was organised last year by the Russian Academy of Sciences and the Notgemeinschaft der Deutschen Wissenschaft, consisting of eleven German members and about thirty Russians representing various branches of science, under the leadership of N P Gorbunov The expedition started in June from Osh (in Turkestan) and went through Gultcha into the Alai valley, then across the Transalai ridge to the alpine lake Kara kul, from there various sections of the expedition radiated in different directions, and the field work went on until November Scientific results of the expedition will take some time to work out fully, but a preliminary account, as published in the *Information Bulletin* of the Russian Academy (No 3 4, for 1929), already gives some idea as to their value

The geographical section of the expedition collected exhaustive information on the areas traversed Of particular interest was a study of Fedtchenko's glacier, which has been found to extend for more than 75 km, that is, it ranks amongst the largest glaciers in the world The topographical section accomplished the enormous task of surveying the wide expanse of Pamir, most of the work had to be done at the altitudes exceeding 4000 metres, which made it exceedingly difficult Nine astronomical and twelve triangulation points were determined, and altitudes of twenty two mountains estimated The meteorological and geophysical section made regular meteorological, aerological, actinometric and hydrological observations, 47 geomagnetic points and 150 gypsometric points were determined The geological section studied the history of the glaciation of the Pamir and prepared a general geological map of the area, the mineralogical collections are very rich and contain proofs of a number of useful minerals

The zoologists of the expedition collected more than 13,000 animals, mainly insects, it was interesting to find some southern forms at very great altitudes, thus at 3700 m, scorpions, Mutillid wasps, *Ammophila, Bombus melamorus*, etc, were found Experiments in hybridisation of *Ovis poli* with the domestic sheep were made and the progeny will be studied in detail Apart from the specimens collected, a considerable number of living local animals was sent from the Pamir to the Moscow Zoological Garden The linguistic section collected materials for a dictionary of the Tadzhik language, made phonograph records of native speech, and studied native customs and folk lore The radio section of the expedition had three transmitting stations at its disposal, apart from keeping in touch with central Russian stations, it made a series of experiments relating to the transmission under the peculiar local conditions A kinematographic section made about 9000 metres of films of all places and phases of the expedition The Alpine section made about thirty ascents to the highest peaks of the Pamir, the greatest height reached being 7120 m (Lenin's peak)

Scientific results of the expedition will be published in parts, as the working out of materials proceeds, it is suggested that the whole series, which will be published partly in Russian, partly in German, will be completed in 1930, apart from detailed monographs on different problems which will be published separately

University and Educational Intelligence

CAMBRIDGE —The Harkness Scholarship in geology has been awarded to L Bairstow, King's College The Anthony Wilkin Studentship in archeology and anthropology has been awarded to J B Charlesworth, of Christ's College

The following reappointments have been made F W Dootson, University lecturer in chemistry, P M S Blackett, University demonstrator in physics R G W Norrish, University demonstrator in chemistry, E M Taylor, University lecturer in agricultural chemistry, E H B Boulton, University lecturer in forestry, H E Woodman University demonstrator in agricultural chemistry, C E Tilley University lecturer in petrology W A Fell, University demonstrator in anatomy, F W Dootson, University demonstrator in chemistry

Dr W M Smart, of Trinity College chief assistant at the Observatory, has been reappointed to the John Couch Adams astronomership

Frank Smart Prizes have been awarded to H R Barnell, of Downing College, in botany, and to R J Pumphrey, of Trinity Hall, in zoology

The syndicate to consider the organisation and finance of the Botanic Garden has reported to the University The most important of its recommendations are the following

(1) The Botanic Garden should become an integral part of the Department of Botany and the responsible head of the Garden should be the professor of botany

(2) The duties of the Director of the Garden should be general responsibility for the management of the Garden and particular care for its development as an aid to the study of botany

(3) The stipend attaching to the office of Director should be variable according to the nature of the other offices held simultaneously by the Director

(4) A new University lectureship should be created for the teaching of systematic botany

(5) Consideration should be given to the fact that a part of the land adjoining the Garden could be sold under suitable restrictive conditions without detriment to the present or future needs of the Garden

(6) The town of Cambridge should be invited to contribute to the cost of the Garden, so long as it is made accessible to the general public

GLASGOW —Prof J W Gregory, having attained the age of sixty five years during the past session, has resigned the chair of geology in the University which he has held since 1904 Prof Gregory is not subject to the age limit regulation, but he has decided to retire to make way for a younger man and to devote his time to the completion of work in which he has been engaged

Among others, the honorary degree of LL D was conferred on June 19 on Prof H S Carslaw, professor of pure and applied mathematics, University of Sydney, Madame Marie Curie, of Paris, The Earl of Elgin, chairman of the Carnegie United Kingdom Trust, C O Hawthorne, chairman of the Repre

sentative Body of the British Medical Association, and Lord Lugard, ex Governor of Nigeria

LIVERPOOL —The Council of the University, at its meeting on June 18, elected Dr D B Blacklock, professor of tropical diseases of Africa, to the Walter Myers chair of parasitology Prof Blacklock is a graduate of the University of Edinburgh From 1911 until 1914 he was in turn assistant director and director of the Runcorn Research Laboratory In 1914 he became a member of the commission appointed to investigate the problems of sleeping sickness in West Africa, and was elected to a lectureship in parasitology in the University of Liverpool During the War period he was in charge of a pathological laboratory and conducted investigations on malaria on behalf of the War Office Prof Blacklock has been secretary and a vice president of the Tropical Section of the British Medical Association and has played an active part in the promotion of tropical medical research

At the same meeting the Council appointed Mr E C Titchmarch to the chair of pure mathematics in the University, and Dr J H Orton to the Derby chair of zoology Mr Titchmarch, a scholar of Balliol, was appointed in 1923 to a lectureship in mathematics at University College, London, and to a fellowship of Magdalen College, Oxford Since 1925 he has been reader in mathematical analysis in the University of London Dr Orton is a graduate of the Royal College of Science, London In 1914 he was appointed assistant naturalist at the Marine Biological Laboratory, Plymouth, and after War service returned to the laboratory, in which he was promoted in 1924 to the post of chief naturalist He has conducted extensive research on problems of marine biology, paying particular attention to the life history of the oyster

MANCHESTER —A limited number of research scholarships in technology, each of the value of not more than £100, are to be awarded in July by the Manchester Municipal College of Technology Application forms, returnable by, at latest, July 6, can be obtained from the Registrar of the College

KING'S COLLEGE, London, celebrated during the past week the hundredth anniversary of its foundation The celebrations, inaugurated on Tuesday by their Royal Highnesses the Duke and Duchess of York, included the dedication of the chapel and opening of the library and new wing of the Vincent Square hostel by the Archbishop of Canterbury, who is the official Visitor Beginning in 1829 with work of university standard in arts, science, and medicine, and a 'junior department' which became the present King's College School at Wimbledon, the growth of the College has been marked by the establishment of an engineering department in 1838, a hospital (now on Denmark Hill) in 1839, a theological department for the training of clergy in 1847, evening classes in 1856, a department for women (in Kensington) in 1885, and a teacher training department in 1890 The post War years have seen a remarkable further enlargement of its activities and increase in the number of its students, with the result that additional accommodation is urgently required, especially in the departments of chemistry and anatomy The building scheme designed to meet this need at a cost of £125,000 will, if carried out, improve the architectural amenity of the Thames frontage in the neighbourhood of Waterloo Bridge For this, and for the endowment of professorial chairs and scholarships the College is asking the public to subscribe to its centenary appeal fund

Calendar of Patent Records

June 29, 1722 —A patent was granted on June 29, 1722, to Martin Triewald, the Swedish engineer, for his invention of a "certain engine or machine for drawing water out of mines and collyeries by the power of the atmosphere" Triewald, who was in England when the first Newcomen engines were [illegible] set up and himself helped in the erection of one, built the first engine in Sweden, that for the Dannemora mines, and is the author of the earliest monograph on the steam engine, which was published at Stockholm in 1734 Triewald claims to have made improvements on the engine, but what these were and what was the construction for which his patent was granted he does not say

July 1, 1769 —The stamped brass trade dates from the patent of John Pickering, whose specification was enrolled on July 1, 1769 The invention consisted of a "new method of performing that kind of work commonly called chasing in gold, silver, brass, tin, or other metal, by a machine consisting of an oblong frame with two rods, in which a moving forcer is worked upon a striking block with a die fixed thereon formed for each respective purpose, whereby the work is executed in a much more expeditious manner and far superior to anything of the kind (not being actual chasing) ever yet performed by any other means"

July 1, 1877 —There was no common patent law for Germany before 1877, but for many years patents had been granted by the constituent States under their respective laws and regulations The first patent law of the German Empire, superseding the various State laws, came into force on July 1, 1877, and the first patent under it dates from the following day

July 3, 1769 —The practical application of the principle of roller drawing in cotton spinning is due to Sir Richard Arkwright, whose patent for the invention was sealed on July 3, 1769 Arkwright was partnered and greatly helped in the establishment of the industry which was started at Cromford Mill, Derbyshire, by Jedediah Strutt, the inventor of the rib stitch hosiery frame

July 3, 1861 —The manufacture of mechanical wood pulp for papermaking was the invention of F G Keller in 1845, but its commercial introduction and development are mainly due to Heinrich Voelter, papermaker, of Heidenheim, who was granted a Prussian patent for five years for his improved process on July 3, 1861

July 4, 1767 —On July 4, 1767, there was granted a patent to John Winn, a shipwright of Shadwell, for a method of saving life "in case of a ship being in distress on a lee shore where a boat cannot live" Ropes were sent ashore by means of a buoy, and the passengers and crew were then transported in a basket slung on one of the ropes and hauled to the shore

July 6, 1897 —The patent of Walther Nernst, of the University of Göttingen, for the electric lamp which is known by his name, was granted in Germany on July 6, 1897 At the time of its introduction, practically no improvement had been made in the earlier carbon filament lamp, other than in the details of the manufacturing processes, and Nernst utilised for his lighting element one of the refractory rare-earths, which allowed a current to pass after a preliminary heating, and withstood a greatly increased temperature He succeeded in reducing the consumption from the 4 watts per candle power of the carbon filament to 1 5 watts The lamp has now been very largely displaced by the metal filament lamp

Societies and Academies

LONDON

Royal Society June 13 —W S Stiles The scatter … theory of the effect of glare on the brightness … threshold The theory that the observed increase in the threshold due to the presence of a glare source in the field is caused by light scattered in the eye media is formulated mathematically Deductions from it are not in accord with observation The general conclusion is that the scattering effect can play only a subsidiary part in increasing the threshold Grace Briscoe and Winifred Leyshon Reciprocal contraction of antagonistic muscles in peripheral preparations using flashing neon lamp circuit for excitation of nerve Controlled and co ordinated rhythmic movements of a limb closely resembling natural movements are produced by suitable artificial stimulation of out efferent nerves If during this controlled rhythmic movement the mechanism producing phasic variation is stopped at any point the limb remains held in posture The method of stimulation is thus adequate for both movement and posture An analysis of the forces controlling movement shows that the control of relaxation is as important for smooth co ordination as the control of contraction —T Moran Critical temperature of freezing living muscle Up to 40 per cent of the water in amphibian muscle can be removed by freezing or drying and its original state completely recovered by restoring water On removal of 78 per cent the muscle immediately dies The critical water removal of 78 per cent corresponds to the freezing of the muscle to equilibrium at about 2° C Muscles frozen to equilibrium below 2° C undergo marked changes on thawing —E C Smith The formation of lactic acid in muscles in the frozen state Freezing (that is drying) upsets the balance making production exceed removal This upset is due to or accompanied by injury to the mechanism Below 1 6° C the mechanism of removal is destroyed that of production persisting Is the mechanism of removal the living part?—F M L Sheffield Chromosome linkage in *Oenothera* with special reference to some F_1 hybrids Most results can be brought into line with Cleland s hypothesis—absence of pairing due to lack of harmony between homologues Chromosome linkage may be inherited as a genetic character —A C Downing and A V Hill A new thermopile for the measurement of nerve heat production —A V Hill The heat production and recovery of crustacean nerve The heat production of crab s nerve in response to maximal excitation is at least $2\ 5 \times 10^{-5}$ calorie per gram of moist nerve per second of stimulus This is 33 times as great as in frog s nerve The crab s nerve is highly fatiguable The initial process, completed during stimulation, yields only about 2½ per cent of the total heat the recovery process lasting for 25 minutes at 16° C supplies the rest In respect of fatiguability and of oxygen requirement a crab s nerve probably presents a closer analogy to certain characteristics of the central nervous system than does a frog s sciatic

PARIS

Academy of Sciences May 22 —The president announced the death of M Depéret, non resident member, and of M Cornet foreign *correspondant* for the Section of Mineralogy —Léon Guillet, Jean Galibourg, and Michel Samsoen Extension tests at high temperatures Data are given for the elastic limits at 450° C for various alloy steels, including nickel, nickel-chromium, and nickel chromium-molybdenum steels No general conclusions can be drawn from the results but the previous heat treatment certainly has a considerable influence on the elastic characteristics at 450° C —Eduard Čech Some remarks relative to the differential projective geometry of surfaces —C Pawlowski Remarks on the disintegration of aluminium Discussion of the results obtained by the author and by Rutherford and Chadwick on the H rays of aluminium —Y Rocard The fall of a heavy gas in a light gas The stability of ozone in the upper atmosphere From considerations based on the kinetic theory of gases it is concluded that the velocity of ozone in nitrogen would be 22 metres per day and of ozone in hydrogen 17 metres per day In either case the atmospheric ozone is practically stable —L Genevois The variations of the respiratory intensity and of the intensity of fermentation in the tissues of the pea —Bounhiol Respiration in media containing an excessive percentage of oxygen The fact has been established by previous workers that animals breathing an atmosphere containing an excess of oxygen rapidly die Under these conditions there is a rapid increase in the proportion of urea in the blood and the accumulation of oxidation products in the blood prevents the fixation of fresh oxygen —L Lutz The soluble ferments secreted by the hymenomycete fungi The alkaloids and the anti oxygen function

LENINGRAD

Academy of Sciences (*Comptes rendus* No 2) —P P Lazarev Modern treatment of malignant tumours from the point of view of the ionic theory of excitation The success of treatment of malignant tumours by calcium salts is explained by the suggestion that calcium ions inhibit the development of tumour cells while those of potassium and sodium favour it V Vernadskij The concentration of radium by living organisms Radium from water solutions is absorbed by aquatic organisms both vegetable and animal and is concentrated there from solutions in soil it is absorbed by terrestrial plants and from drinking water by terrestrial animals In some cases the concentration of radium in an organism was found to exceed that in water 56 5 times —V Vernadskij Rare earths elements in massive rocks Minerals rich in rare earths are found mainly in pegmatite seams but their occurrence in the rocks proper is not clear probably because of insufficiently exact methods of examination —V Vernadskij The geochemical constants of some cultivated plants Geochemical energy of the best selected varieties is less than the energy of the varieties usually cultivated —A Vinogradov Chemical composition of plankton from the Ekaterininsky pond at Dietskoe Selo, near Leningrad —D Grave Magnetic anomalies A reply to the critical note by Kravetz (*Comptes rendus*, p 470 1928) —N Olenev Systematics and geographical distribution of Ixodidæ (3) The genus *Rhipicephalus* is represented in Russia by three species *R sanguineus* Latr *R bursa* Can et Fanz, and *R schulzei*, sp n The genus *Boophilus* is represented only by *B calcaratus* Birula The geographical distribution and hosts of each species are given —G Veretschagin and I Sidorytchev Winter chemical regime of the rivers Selenga and Uda The oxygen content of the water decreases sharply from the end of November and reaches its minimum early in February parallel to that process the carbon dioxide content increases This must be of great importance to fish life

(*Comptes rendus*, No 3) —V A Silberminz The deposits of cerite, bastnæsite, and a new mineral, lessingite, in the Kyshtym district Urals The deposits are described, and descriptions and chemical

analyses of the three minerals are given —**A Mordvilko** The anolocyclic plant lice of *Pistacia* and the distribution of pistachios during the Tertiary period The genus *Pistacia* was very widely distributed in the Tertiary, extending northwards as far as Greenland, where the plant lice *Triphidaphis phaseoli*, representing a migrant form from pistachios, survive until the present time While *Pistacia* disappeared in such high latitudes under the influence of cold climate, it is impossible to account in the same way for the disappearance of *Pistacia* in some Mediterranean countries where in places only root forms of pistachio aphids are to be found at present — **A Frank-Kamenetskii** The fat of *Phoca sibirica* Gmel Physical and chemical properties of the fat are described fully —**D D Ivanenko** A geometrical generalisation which may be useful in the quantum mechanics

(*Comptes rendus*, No 4)—**P Lazarev** The causes of plasticity of substances The greater plasticity of loam as compared with sand is due to the ability of particles of loam to bind water on their surfaces Capillarity must also play some part in the plasticity - **L A Kulik** The Mamra meteorite A description of a meteorite which fell at Mamra in Kazakstan (Kirghiz Steppes) at night on May 5, 1927 The meteorite belongs to the stony meteorites and, probably, to sulphurous chondrites —**V I Romanovskii** The law of probability of frequencies subject to linear conditions and Pearson's criterium χ^2 —**A A Birula** The pelvic bone of *Rhytina stelleri* Oser Amongst the semi fossil remains of *Rhytina stelleri* found at the Komandor islands, pelvic bones are rare , a detailed description of one such bone is given and illustrated —**A A Birula** A preliminary communication on the mammals of the kitchen midden of a Stone Age habitation on the Verkholensk mountain near Irkutsk Remains of twelve species of mammals have been identified —**N Smirnov** Diagnoses of some geographical varieties of *Phoca hispida* Schreb Two new subspecies and one new form are described — **E G Shramkov** The stability of the permanent magnetism of some rocks —**B V Numerov** The relation between the local anomalies of gravity and the derivatives of the potential

PRAGUE

Czech (Bohemian) Academy of Arts and Sciences (second class, Natural Sciences and Medicine), Mar 8 —**J Petrbok** Stratigraphy of the Pleistocene and Holocene in the plain of Arsuf in Palestine —**Fr Cechura** Geomagnetic examination of the contact of Algonkian and granite near Příbram —**J Sekanina** The symmetry of tourmaline —**J Hýbl** The dependence of saturated vapour pressure on temperature The author tested various formulæ with the vapour pressure data of liquid carbon dioxide, sulphur dioxide, ammonia, water, and hydrocarbons , the best record is given by a shortened formula of Kamerlingh Onnes : $\log p = a - \frac{b}{T} - cT + dT^2$ —**Jar Hahn** *Monocystis Mrázeki* —**J Křepelka** and **F Toul** The dissolution of silver in water Silver passes as Ag^+ into water containing atmospheric gases, being oxidised The amount, determined by nephelometry, potentiometry, and conductance, varies between 0 01 mgm and 0 037 mgm Ag^+ per litre —**K Petr** The composition of *n* ary quadratic forms —**E Votoček** and **F Rác** The identity of E Fischer's quinovose with *d* glucomethylose (isorhodeose) Reduction of quinodose with sodium amalgam and identification of the methylpentite obtained with isorhodeite leads the authors to the same conclusion as Freudenberg and Raschig on the isolation of crystalline quinovose

ROME

Royal National Academy of the Lincei, Mar 17 — **P Vinassa de Regny** The law of simple parametral relations and the distances of the components of the solar system It has been recently shown that Haüy's law concerning simple and rational parametral relations holds not only for crystal lattices, but also for the distances of the electrons from the atomic nucleus A similar relationship is now shown to exist in the cases of the sun's planets and of the satellites of Mars, Jupiter, Saturn, and Uranus — **E Soler** The second gravimetric campaign on the Carso Measurements made in 1926 at S Canziano give for the gravitational constant the observed values, 980 568 cm outside and 980 604 inside the cave, these becoming 980 698 and 980 696 respectively when corrected for the reduction in free air, and 980 661 and 980 684 when Bouguer's and topographical corrections are applied The discrepancy between these values is considerably greater than the mean errors and is to be discussed later The normal gravity value, derived from Helmert's formula (1901), is 980 676 cm —**U Pierantoni** The symbiotic organ of *Silvanus surinamensis* (L) —**G Bemporad** Photographic position of planet (1036) —**T Boggio** Hypersurfaces of spaces of constant curvature — **V Glivenko** Certain general forms of the law of large numbers — **A Kolmogoroff** The law of large numbers —**Maria Pastori** Total and partial commutation relative to derived tensors – **G Scorza-Dragoni** The continuous dependence of the integrals of the equation $y' = f(x, y)$ on the initial values —**Pia Nalli** The principal value of an integral —**S Finikoff** The congruences of Demoulin —**M Manarini** The motion of two variable masses which attract one another according to Newton's law Vranceanu's equations (1928) have indicated the difficulty of this problem, but the introduction of a simple and plausible hypothesis regarding the variation of the masses furnishes a means of simplifying the investigation and of obtaining results comparable with those of Armellini (1915) and of Pizzetti (1915) —**A Clementi** investigations on arginase (7) Ureotelic character of the nitrogen metabolism of Chelonia The urine of *Testudo Græca* and *Emys Europæa*, like that of *Bufo*, contains uric acid in very small proportions only, which are usually too minute to be determined In the summer season the content of urea in the urine of these two organisms corresponds approximately with that in the urine of *Bufo* at the same period, namely, about 0 5 part per 1000 Oral administration of ammonia to *Testudo* and *Emys* causes a very marked increase in the urea content *proprio* and per 1000 of the urine, this being contrary to what is observed with uricotelic animals (birds) Hence, the nitrogen metabolism of the Chelonia is not, as with other reptiles and with birds, uricotelic, but ureotelic —**V Rivera** Experimental cicatrisation of the stem of *Ricinus communis*, determined by *Pseudomonas fluorescens* (Flugge) Migula Cuts made aseptically in the stem of *Ricinus*, and afterwards inoculated with a pure culture of *Pseudomonas fluorescens*, gradually seal up as a result of pronounced cellular proliferation at the sides of the cut, whereas control cuts, uninoculated, undergo no such sealing It may, therefore, be assumed that this organism, which is of universal occurrence, is the cause of the cicatrisation often observed after a root or a stem has been wounded

WASHINGTON, D C

National Academy of Sciences (*Proc* , Vol 15, No 2, Feb. 15) —**Arthur M Banta** and **L A Brown** Control of sex in Cladocera (3) Localisation of the critical period for control of sex Females of *Moina macrocopa*

produce parthenogenetic eggs or, under adverse conditions, sexual eggs Crowding of the females leads to production of eggs giving males, the critical time for crowding is about four hours (at 20° C) before oviposition, which is more than three hours before spindle formation in the nuclei —**Chas W Metz** and **Silka S Ullian** Genetic identification of the sex chromosomes in *Sciara* (Diptera) The males alone of these dipterans have two peculiar 'sex limited' chromosomes, but these chromosomes are transmitted by all sperms Sex chromosomes distinct from these have been detected by tracing the inheritance of a sex linked character, swollen wing veins —**Gregory Pincus** A spontaneous mutation in the house mouse —**G A Miller** Possible n automorphisms of non Abelian groups —**W L Ayres** (1) On continuous curves having certain properties —(2) On simple closed curves and open curves —**I A Barnett** On a relation between conformal and projective groups in function space —**Francis D Murnaghan** On elements of content in metrical geometry —**G C Evans** and **E R C Miles** Potentials of general masses in single and double layers The relative boundary value problems —**H S Vandiver** Summary of results and proofs on Fermat's last theorem (4) —**Francis B Sumner** The analysis of a concrete case of intergradation between two subspecies A mouse, *Peromyscus polionotus*, common in Florida and Alabama, has two races distinct in several characters, one existing on the coastal region and the other inland The races are interfertile, but trapping them at a line of stations running inland shows an abrupt transition from one to the other The coastal form seems to have arisen from the inland or a similar ancestral race, in adaptation to life on a background of pale sand —**Edwin B Wilson** and **Margaret M Hilferty** Note on C S Pierce's experimental discussion of the law of errors The mean and standard deviation for many observations of an identical experiment repeated on 24 days vary much more than is predicted by the law of errors —**Edwin H Hall** Photoelectric emission and thermionic emission once more A theoretical criticism of experiments suggesting that photoelectric and thermionic work functions are equal —**Gilbert N Lewis** and **Joseph E Mayer** The quantum laws and the uncertainty principle of Heisenberg In earlier papers, the second and third laws of thermodynamics were deduced from a single statistical principle implying that the properties of a system can be described by assuming a finite number Ω of possible states Assuming that Ω is a minimum *sufficient* to account for the whole *behaviour* of a system, the fundamental laws of the quantum theory are developed —**E L Nichols** and **H L Howes** The transformation spectrum of the ruby An incandescent ruby gives a continuous spectrum on which is superimposed a system of narrow emission bands The latter appear in the temperature range corresponding to changes in the absorption of light by the ruby and occur in sets, including also the absorption and fluorescence bands of the ruby, with a constant frequency interval —**Leonard B Loeb** and **Karl Dyk** The effects of a homologous series of amines on the mobilities of ions in hydrogen gas With *N* propyl amine, there is a large initial drop in mobility of both positive and negative ions With methylamine the negative ion mobility is decreased but the positive ion mobility is unaffected Although the results are consistent with the formation of addition products with only one or two molecules, this explanation is not accepted —**Marius R Campbell** Late geologic deformation of the Appalachian Piedmont as determined by river gravels The rocks of this region are old, but minor flexures of more recent date have been discovered by tracing high level gravels in the area. Sections and a map are given

Diary of Societies.

FRIDAY, JUNE 28.

PHYSICAL SOCIETY (at Imperial College of Science), at 4 45 —Dr Teresa J Dillon The Relation between Hydrogen Pressure and Filament Resistance in a Tube containing Glowing Tungsten.—Dr Frances Lowater The Band Systems of Titanium Oxide —F E Smith The Absolute Measurement of Sound Intensity —A Demonstration of an Apparatus for the Measurement of Electrical Resistance at High Temperatures will be given by Dr J L Haughton.

MONDAY, JULY 1

ROYAL SOCIETY OF EDINBURGH, at 4 30 —Gunning Victoria and Makdougall Brisbane Prizes to be presented —Prof R. A Sampson and Prof A E Conrady Description of Three Huygens Lenses in the Possession of the Royal Society of London —W J M'Callien The Metamorphic Rocks of Kintyre —Dr T M Finlay Old Red Sandstone of Shetland (North Western Area).

ROYAL INSTITUTION at 5 —General Meeting

TUESDAY, JULY 2

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (jointly with Institution of Engineers and Shipbuilders in Scotland) (at Newcastle upon Tyne), at 10 A M —Sir Westcott S. Abell The Story of Safety at Sea.—J Ireland The Applications of Monel Metal in Engineering and Shipbuilding

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham), at 11 A M.

ROYAL SOCIETY OF MEDICINE, at 4 30 —Annual General Meeting

BRITISH WATERWORKS ASSOCIATION (at Portsmouth) (continued on July 3, 4, and 5).

WEDNESDAY, JULY 3.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (jointly with Institution of Engineers and Shipbuilders in Scotland) (at Newcastle upon Tyne), at 10 A.M —J L Adam Some Notes on Damage to Ships —R P Sloan Developments in the Uses of Electricity

FRIDAY, JULY 5

INSTITUTION OF CIVIL ENGINEERS (Birmingham and District Association), at 8.30 A M —Visit to Liverpool to see the Work in connexion with the Mersey Tunnel

OVERHEAD LINES ASSOCIATION at 12 15 P M —Visit to the Mid-Cheshire Electricity Supply Company

GEOLOGISTS' ASSOCIATION (in Architectural Theatre University College, Gower Street), at 7 30.—Christopher T A Gaster Chalk Zones in the Neighbourhood of Shoreham, Brighton, and Newhaven, Sussex.—H G Smith Some Features of Lamprophyres, near Sedbergh, Yorkshire

SATURDAY, JULY 6

PHYSIOLOGICAL SOCIETY (at Oxford).

TUESDAY JULY 9

SOCIETY OF CHEMICAL INDUSTRY (at Manchester), at 10 15 A M —Annual General Meeting —Dr A. D Little Science and Labour

WEDNESDAY JULY 10

SOCIETY OF CHEMICAL INDUSTRY (at Manchester), at 10 A.M —Annual Meeting.—Prof T H Pear The Human Factor in Industry —Dr A. D Little Process Development.

INSTITUTION OF MINING ENGINEERS (at University College, Nottingham), at 11 A.M —General Meeting —Dr W Hancock A G R. Whitehouse, and Dr J S Haldane The Salts lost by Sweating owing to High Air-temperatures (Sixteenth Report to the Committee on The Control of Atmospheric Conditions in Hot and Deep Mines).—Dr J S. Haldane Work of the Committee of the Institution of Mining Engineers on The Control of Atmospheric Conditions in Hot and Deep Mines.—The following papers will be submitted for further discussion —W S. Cooke and I C F Statham The Flow of Air at Bends and in Straight Airways (Sixth Report of the Midland Institute Committee on the Ventilation of Mines).—Dr T David Jones Spontaneous Combustion in North Staffordshire. Part II A Record of Analyses of Air-samples taken during the Combating of a Fire.—Dr T F Wall: Electro-magnetic Testing of Wire Ropes.—2.15 —The General Meeting will be resumed —3 30 —The General Meeting will be closed.

CONFERENCE.

JULY 1 TO 5

MUSEUMS ASSOCIATION (at Worthing).

Monday, July 1

Tuesday, July 2, at 10 A.M. (in Connaught Hall).—Sir Henry A. Miers Co-operation—the Association's Task (Presidential Address).—Reading and Discussion of Papers.

At 3 (in Connaught Hall).—Reading and Discussion of Papers.

Wednesday, July 3, at 10 A.M. (in Connaught Hall).—Reading and Discussion of Papers bearing on the Co-operation of Museums in this Country and throughout the Empire, and on the Work of the Association in this Connexion.

At 2 15 (in Connaught Hall).—Reading and Discussion of Papers.

Thursday, July 4, at 10 A M.—Reading and Discussion of Papers.

At 11 30 A.M —Annual Business Meeting.

Friday, July 5 —Excursions.
